These diesel train emissions were accounted for by adding the train emissions to the motor traffic-related emissions in the CAL3QHC model. Diesel locomotive emission factors were based on USEPA guidance reproduced in Appendix 4.9-A.[12] As a result, the air quality modeling for the diesel alternatives represents the total air quality impact. As discussed below, analysis also considered the impact of diesel locomotives idling at the stations (and thus generating higher pollutant concentrations than would occur with a moving train).

For the diesel Build Alternatives, two scenarios were evaluated in the analysis of each receptor; the train idling in the station and the train traveling along the rail line. The first scenario was analyzed by treating the train idling at the station in the CAL3QHC model as an unsignalized intersection with the train sitting idle for 70 seconds of the 120 second cycle which equates to a conservative 35 minutes of idling during an hour. The emission factors used for the train idling were the “Large Switch” emissions factors which are the closest locomotive emission factors for “idling” available in the USEPA guidelines. In addition to the train idling, a moving train along the rail line was also analyzed at each receptor. These moving trains were assessed as freeflow links in the CAL3QHC model and assumed “Passenger Commuter Rail” locomotive emission factors from the USEPA guidelines. The number of trains on the freeflow links (a maximum of 5 trains per hour) was based on the estimated rail schedules. The locomotive emissions factors assumed in the air quality analysis reflect the assumption that all locomotives added to the rail corridor for the South Coast Rail project would be new locomotives.

Analysis of Sensitive Areas for NO_x—In addition to air quality analysis conducted for the intersections in proximity to the stations, the impacts of the alternatives on air quality in the vicinity of proposed overnight layover facilities were examined. USEPA’s atmospheric model AERMOD modeling procedures were used to model locomotive emissions at stations, layover facilities, and environmentally sensitive areas, such as the Hockomock Swamp. AERMOD is appropriate for chemically stable, gaseous or fine particulate pollutants, such as CO, NO_x, and PM. It incorporates multiple sources, meteorological data, source emission data, stack and building geometry, and detailed surrounding land use and topography. These data were incorporated into AERMOD to generate concentrations that demonstrate whether or not the proposed project would comply with the NAAQS or cause air impacts.

Mesoscale Analysis Methodology

The predominant sources of regional pollution impacts anticipated from the proposed South Coast Rail project are emissions reductions resulting from modal travel shifts from private automobiles to rail service. The mesoscale analysis uses traffic and emissions data for existing and future (No-Build and Build) conditions for each alternative. The general modeling process to determine whether the alternatives would have air quality impacts utilized link-by-link data from the Central Transportation Planning Staff (CTPS) state-wide traffic model and emission factors derived using the USEPA’s MOBILE6.2 emission factor model. The link-by-link traffic data includes daily vehicle volumes as well as free flow and congested speeds over each link. The vehicle volumes are combined with the link lengths in order to determine the daily VMT over the link. The VMT is then multiplied by the appropriate speed-specific emission factors in order to arrive at the total daily emissions for each link.

The roadways included in the mesoscale study area include the roadways coded in the CTPS state-wide model and generally includes Eastern Massachusetts. The mesoscale analysis estimated the future regional VOCs, NO_X, CO_2, CO, and PM emissions due to the changes in average daily traffic volume,

[12] Emission Factors for Locomotives United States Environmental Protection Agency, Office of Transportation and Air Quality, EPA-420-F-09-025 April 2009.

roadway characteristics, and vehicle emissions. The mesoscale analysis traffic (volumes, delays, and speeds) and emission factor data were developed for the above listed conditions.

The objective of the mesoscale analysis was to estimate the change in area-wide emissions of ozone precursor VOCs, NO_X, CO, and PM emissions during a typical day and CO_2 emissions during the entire year resulting from implementing the proposed South Coast Rail project. The daily area-wide emissions are presented in kilograms per day to be consistent with conformity criteria and SIP budgets and in terms of tons per year to be consistent with Massachusetts GHG policy.

The air quality study used traffic data (volumes, delays, and speeds) developed for each analysis condition. The microscale analysis used the evening peak hour traffic conditions during the CO season (winter). The mesoscale analysis for VOC and NO_x emissions used typical daily peak and off-peak traffic volumes for the ozone season (summer). Vehicle speeds are developed based upon traffic volumes, observed traffic flow characteristics, and roadway capacity.

Stationary Source Air Quality Modeling Methodology

Stationary source analysis for greenhouse gases included direct and indirect CO_2 emissions. The following outlines the stationary source analysis approach for the proposed stations and layover facility alternatives.

Station Analysis—A stationary source analysis was not conducted for the stations because there are no buildings proposed as part of the stations for the South Coast Rail project. The stations would only include a platform. There are some electrical requirements for each station but the emissions related to the minimal electrical requirements are considered negligible.

Layover Facility—A stationary source analysis was conducted for the layover facilities and is presented in Section 4.9.3.8. The stationary source analysis assessed the emissions due to the trains idling and/or plugging-in at the layover facilities. The layover facilities would be open buildings with no heating fuel emissions.

Greenhouse Gas Analysis

The Massachusetts Executive Office of Energy and Environmental Affairs has established a GHG emissions policy. The policy requires that proponents of projects undergoing MEPA review quantify greenhouse gas emissions and identify measures to avoid, minimize, and mitigate those emissions. MEPA has developed procedures and guidelines for implementing this policy, which was originally released in 2007. The most recent version of the policy was released in 2010 with an effective date of May 5, 2010.

The MEPA Certificate for the South Coast Rail project called for the GHG modeling of direct and indirect sources. These sources include motor vehicles, buses, diesel trains, electric trains, stations, layover facilities, and buildings.

Additional GHG effects, including an assessment of the greenhouse implications of a Smart Growth scenario are discussed in Chapter 5, *Summary of Indirect Effects and Cumulative Impacts*. The Smart Growth scenario analyzed in Chapter 5 is primarily anticipated to affect the GHG emissions caused by motor vehicles, which would be affected by implementing smart growth and transit-oriented development policies. Smart Growth programs include other “green” policies and goals in addition to

transportation improvements, such as building energy efficiency, travel behavior changes, etc. The development patterns associated with the Smart Growth programs, such as Transit Oriented Development in the vicinity of new or existing transit stations may result in different (higher) building densities, and other characteristics, thereby potentially resulting in different GHG reduction benefits, including those recognized by the State under the Global Warming Solution Act (GWSA).

Modeling

Mesoscale mobile source emissions were calculated for all of the major transportation modes in eastern Massachusetts for different years. The modes consist of on-road vehicles such as autos, trucks, and buses as well as certain off-road sources like water transportation and commuter rail. The methodology being used for the South Coast Rail project is the same one that is used for the Federal Certification Activities conducted by the Metropolitan Boston Planning Organization (Boston Region MPO). This methodology has been used in the Regional Metropolitan Transportation Planning process, Air Quality Conformity Determination, and numerous other highway and transit projects.

Mobile vehicle emissions were modeled using USEPA's MOBILE6.2 emission factor model and CTPS's regional travel demand model. This was conducted for existing conditions and No-Build and Build Alternatives. Bus emissions were calculated separately using a mesoscale analysis.

In order to have a net reduction in greenhouse gas emissions, a Build Alternative would have to divert automobile travel to transit to a degree that the reduction in motor vehicle emissions from automobiles would more than offset the increase resulting from a Build Alternative's CO_2 emissions. The extent to which Build Alternatives would reduce greenhouse gas emissions associated with vehicular travel depends on the estimated diversion of the use of motor vehicles to transit. This "mode-shift" from motor vehicles to transit results in reductions of VMT, which reduces motor vehicle emissions. It also contributes to reduction in traffic congestion, which can also reduce vehicular emissions due to lower emissions associated with improved traffic flow, rather than stop-and-go.

Motor Vehicles—The USEPA's MOBILE6.2 emission model for autos and trucks includes:

- Description of the calculation for auto and truck (motor vehicles) emissions as a function of the MOBILE6.2 emission rates and the Regional Travel Demand Models (RTDM) estimate of VMT and congested speed.
- Description of the sources of emissions rates and the method used to calculate pollutant emissions for the public transportation vehicles.
- The end product is the estimate of total emissions for a scenario and year.

The unit for measuring emission rates for motor vehicles is grams per mile and were calculated using MOBILE6.2, the software developed by USEPA. The MPO coordinated with MassDEP to develop the inputs to the MOBILE6.2 model for application by the Boston MPO in their air quality modeling. MOBILE6.2 requires a wide range of input parameters, including inspection and maintenance program information and other data such as hot/cold start mix, emission failure rates, vehicle fleet mix, and fleet age distribution. The inputs used for the 2000 Base Year were the same as those used in determining the latest emissions inventory for the Commonwealth of Massachusetts. The inputs used for the years 2009 through 2035 were also received from DEP and include information on programs that were submitted to the USEPA as the strategy for the Commonwealth to obtain ambient air quality standards.

MOBILE6.2 produces a lookup table showing grams produced per mile of travel; stratified by roadway type, and speed for each pollutants and season. Lookup table 1 contains freeway emission rates for 2035 and Lookup table 2 contains emission rates for arterials. Emissions rates are provided for the greenhouse gas (CO_2) using MOBILE6.2. It should be noted that the current MOBILE6.2 emission factor model can only generate a CO_2 grams per mile based on fleet average fuel economy for the year modeled and does not vary based on vehicle speed, or roadway type. USEPA's next motor vehicle emission model, "MOVES -Motor Vehicle Emissions Simulator", provides improved capabilities for assessing greenhouse gas emissions, but was not available for official use at the time this study was prepared.[13]

The calculation of emissions for the greenhouse gas (CO_2) produced by motor vehicles, including park-and-ride and kiss-and-ride trips are a function of four factors:

- VMT
- Congested speeds on the roadways
- Type of roadway (limited access vs. full access)
- Emission factors for the pollutants from MOBILE6.2 by season

The Regional Travel Demand Model (RTDM) includes every major highway, arterial, and collector in the study area. The centroid connectors are a proxy for the local roads. These roadways are represented as links, segments of roadways that have motor vehicles assigned to them in each alternative. Each roadway link and centroid connector has a roadway type and distance associated with it. The highway assignment process calculates how many vehicles are on each link and centroid connector and what its congested speed would be by time of day. VMT is a function of how many vehicles are on a link and the length of that link. This parameter was calculated for every link in the model area. The emission factors were held constant in this study for 2035.

The emission factor for CO_2 identified for each link and centroid connector based on its roadway type and congested speed. The emissions produced on each link and centroid connector was simply the product of the emission rate for CO_2 and the VMT. The total emissions were simply the sum of CO_2 for all of the links in the study area by time period. The four time periods are summed to arrive at an emission estimate for an average weekday in 2035.

Observed emission changes are due to mode shifts from auto to transit, resulting in lower VMT and possibly lower congested speeds on the roadway network. Hence, the more auto diversions there are, the more likely the air quality measures will improve from this mode.

Train Emissions—Diesel train emissions were modeled using the most recently approved USEPA train emission factors and the train network and volumes as discussed below. The electric train emissions are modeled based upon the amount of electricity that they use which is also discussed in more detail below.

[13] The Notice of Availability approving the MOVES2010 model for SIP development and transportation conformity regional emissions analysis was published in the Federal Register on March 2, 2010. A two-year grace period is provided before MOVES2010 is required for new regional emissions analyses. At the time of the preparation of the DEIS/DEIR, MOVES2010 had not yet been approved for project-level CO and PM hot-spot analysis pending the release of EPA guidance and a separate Federal Register notice.

The South Coast Rail train emissions are calculated by using the USEPA passenger/commuter train emission factors and the total distance between South Station and the endpoints of the Southern Triangle for each alternative. Estimates of rail emissions in the Eastern Massachusetts region are based upon the factors received by CTPS in 2009 guidance from the USEPA Office of Transportation and Air Quality (OTAQ) and documented on their web site at: www.epa.gov/otaq/locomotives.htm.

The number of train miles is estimated from a breakdown of track mileage by train line and community. Train mileage is a function of the train frequency data using present, and proposed commuter rail schedules. Multiplying the train miles per day by the vehicular emissions per train mile yields the estimated vehicular emissions per day in the Eastern Massachusetts for CO_2. Using the CO_2 emission factors provided by the E.P.A. (Emission factor = 3405.67 g/mile), the total emissions for each alternative for the years 2016 and 2030 are calculated as follows:

- Total CO_2 Emissions (by alternative) = CO_2 Passenger/Commuter Train Emission Factor (tons per year)* Total Distance Traveled by each Train * Number of trains per day

Similarly, the project CO_2 emissions produced by the electric trains in the electric alternatives were also calculated. The total amount of travel time is calculated for each train per trip, which includes the time for traveling round-trip plus the amount of time to move to the layover facility and back to the terminal station. The projected electric consumption for each train trip is calculated as follows:

- Total electric consumption = Kilowatts consumed by 1 train per trip * the amount of travel for each train trip time required for each trip (in kilowatt-hours (kWh))

The electric consumption for each train per trip in kWh is then converted into tons of CO_2 per year as follows:

- Total GHG consumption = kWh * 1megawatt-hours (mwh)/1,000kwh * number of trains per day * 1,107lbs/Mwh *0.0005 tons/lbs*365 days/year

The emission rate of 1,107 lbs of CO_2 per mwh is based on the 2005 marginal emission rate for New England electricity generation as calculated by ISO New England Inc.[14] (the New England Independent System Operator [ISO] for electricity). This rate takes into account the various electricity sources used in the New England system (coal, nuclear, natural gas, hydroelectric etc.).

4.9.3 Analysis of Impacts

The following identifies potential long-term air quality impacts resulting from implementation of the alternatives. The discussion of potential air quality impacts begins with the No-Build Alternative and continues to the Build Alternatives including alignments, stations, and layover facilities. Figure 4.8-1 shows the South Coast Rail alternatives and existing stations.

4.9.3.1 No-Build (Enhanced Bus) Alternative

The No-Build Alternative would consist of enhancing current bus service along existing roads and highways. It was assumed that the limited increase in bus service along the roadways would have a minimal effect on the air quality within the study area. Table 4.9-2 presents a summary of the air quality

[14] See the ISO New England Inc. 2007 New England Marginal Emission Rate Analysis, Table 5.6. http://www.iso-ne.com/genrtion_resrcs/reports/emission/2007_mea_report.pdf.

levels for the mesoscale (regional) analysis for the Existing Conditions and No-Build (Enhanced Bus) Alternative for the various pollutants.

Table 4.9-2 Mesoscale No-Build Analysis Emissions Results

	Units	2010 Existing	2035 No-Build
Vehicle Miles Traveled (VMT)	Average Miles/day	109,926,000	118,897,192
Volatile Organic Compounds (VOC)	Kg/day	48,810	22,200
Oxides of Nitrogen (NO_x)	Kg/day	118,010	19,256
Particulate Matter 10 (PM_{10})	Kg/day	4,780	3,240
Particulate Matter 2.5 ($PM_{2.5}$)	Kg/day	3,010	1,490
Carbon Monoxide (CO: Winter)	Kg/day	1,516,100	1,050,356
Carbon Dioxide (CO_2)[1]	Tons/year	22,334,463	24,717,339

1 The CO_2 was calculated assuming an annualization factor of 365 days/year and 1000kg/1 ton.
Note: Emissions quantities rounded to the nearest 10.

The mesoscale and microscale analyses indicate that reductions in pollutant concentrations are expected to occur over time relative to the Existing Condition. With the exception of carbon dioxide, all of the calculated future No-Build regional emissions are less than the existing conditions emissions. These reductions can be mostly attributed to more efficient vehicles with enhanced emissions control technologies and the benefits of the Massachusetts Vehicle Inspection and Maintenance program.

The intersections that were analyzed as part of the microscale analysis are representative of the air quality impacts in the study areas surrounding the proposed train stations. Table 4.9-3 summarizes the results of the No-Build conditions for the microscale analysis. Table 4.9-3 shows the highest CO, $PM_{2.5}$ and PM_{10} concentrations at each intersection under the 2016 and 2030 No-Build conditions. No exceedances of the NAAQS are anticipated.

4.9.3.2 Southern Triangle Study Area (Common to all Build Alternatives)

Portions of the rail lines within the southern part of the South Coast Rail study area are common to all Build Alternatives. These rail lines form a rough triangular shape between the Fall River Secondary and the New Bedford Main Line, and are therefore referred to as the Southern Triangle. The northern part of the South Coast Rail study area is encompassed by the other Build Alternatives described in subsequent sections.

The mesoscale analysis for the Southern Triangle is included in the alternatives analysis presented in this section (Stoughton and Whittenton Alternatives) due to the regional nature of the analysis and the need to analyze the rail line as a whole in order to assess its regional air quality benefits. The following sections summarize the microscale (local) analysis results for the Southern Triangle stations.

Fall River Secondary Rail Segment

The existing Fall River Secondary freight track would be upgraded to Federal Rail Administration (FRA) Class 5[15] for the South Coast Rail project. Public at-grade road/railroad crossings that would remain open would be reconfigured and/or improved to meet current safety standards. The existing freight service using the Fall River Secondary is diesel-powered; no electrical infrastructure is present. New

[15] 49 CFR 213.9 Classes of Track: Operating Speed Limits

catenary supports and wires would need to be constructed along the length of the line and two new traction power facilities would need to be constructed for the electric alternatives. Two new stations would be constructed in Fall River (Battleship Cove and Fall River Depot) and one new station would be constructed in Freetown (Freetown). One new layover facility would be constructed in Fall River, at either the Weaver's Cove site or the ISP site.

Tables 4.9-4 and 4.9-5 summarize the microscale (local) analysis results for the Southern Triangle portion of the project for the Fall River Secondary for the diesel and electric alternatives, respectively. As shown in the tables there are minor differences between the diesel and electric alternatives for the microscale (local) analysis. Figure 4.9-1 shows the microscale air quality study area for Fall River, and Figure 4.9-2 shows the Freetown study area. All of the pollutant concentrations are well below the NAAQS standards for both the diesel and electric alternatives.

New Bedford Main Line Rail Segment

The existing New Bedford Main Line freight track would be upgraded to FRA Class 5 for the South Coast Rail project. Public at-grade road/railroad crossings that would remain open would be reconfigured and/or improved to meet current safety standards. The existing freight service using the New Bedford Main Line is diesel-powered; no electrical infrastructure is present. New catenary supports and wires would need to be constructed along the length of the line, and four or five traction power facilities (depending upon the alternative selected) would need to be constructed for the electric alternatives. Two new train stations would be constructed in New Bedford (Whale's Tooth and King's Highway) and one new train station would be constructed in Taunton (Taunton Depot). One new layover facility would be constructed in New Bedford, at the Wamsutta site.

Tables 4.9-6 and 4.9-7 summarize the microscale (local) analysis results for the Southern Triangle portion of the project for the New Bedford Main Line stations for the diesel and electric alternatives, respectively. Figure 4.9-3 shows the New Bedford microscale air quality study area. As shown in the tables there are minor differences between the diesel and electric alternatives for the microscale (local) analysis. All of the pollutant concentrations for both the diesel and electric alternatives are well below (in compliance with) the NAAQS.

4.9.3.3 Stoughton Electric Alternative

The Stoughton Electric Alternative alignment comprises a portion of the Northeast Corridor, the entire Stoughton line, and the Southern Triangle. This alternative would use the Northeast Corridor only from South Station to Canton Junction. From Canton Junction, the existing Stoughton Line would be used to the Stoughton Station. From there, commuter rail service would be extended, reconstructing a railroad on an out-of-service railroad bed, south through Raynham Junction to Weir Junction in Taunton. This alignment joins the New Bedford Main Line at Weir Junction, the northern end of the Southern Triangle. This evaluation focuses on the existing and extended Stoughton Line segment.

The existing Stoughton Line commuter rail track from Canton Junction to Stoughton Station would be upgraded to FRA Class 5 for the Stoughton Electric Alternative. New track would be placed on the out-of-service railroad bed from Stoughton Station south to Weir Junction. The existing public at-grade road/railroad crossings would be reconfigured and/or improved to meet current safety standards.

The mesoscale analysis represents travel from South Station to the southern end points in New Bedford and Fall River. The difference in average vehicles miles traveled a day between the No-Build and the Stoughton Electric is approximately a 256,000 reduction with the implementation of the Stoughton Electric Alternative. This VMT reduction results in a reduction in all of the study pollutants as well (except particulate matter), as presented in Table 4.9-8.

Table 4.9-8 Mesoscale Mobile Source Analysis Results, Stoughton Electric Alternative

Stoughton Electric	Units	2035 No-Build	2035 Build	Build/No-Build Difference
Vehicle Miles Traveled (VMT)[1]	Average Miles/day	118,897,192	118,641,260	-255,932
Volatile Organic Compounds (VOCs)	Kg/day	22,200	22,160	-40
Nitrogen Oxides (NO_x)	Kg/day	19,256	19,159	-98
Particulate Matter 10 (PM_{10})	Kg/day	3,240	3,240	0
Particulate Matter 2.5 ($PM_{2.5}$)	Kg/day	1,490	1,490	0
Carbon Monoxide (CO: Winter)	Kg/day	1,050,356	1,048,074	-2,281
Carbon Dioxide (CO_2)[1]	Tons/year	24,717,339	24,656,479	-60,859

1 The CO_2 was calculated assuming an annualization factor of 365 days/year and 1000kg/1 ton.

As discussed in the methodology section, the intersections that were analyzed as part of the microscale analysis are representative of the air quality impacts within the study areas surrounding the proposed train stations. Table 4.9-9 presents a summary of the results of the microscale air quality analysis for the stations associated with the Stoughton Electric Alternative. Figures 4.9-5, 4.9-6 and 4.9-7 show the microscale study areas for the Stoughton Electric Alternative. The highest CO, $PM_{2.5}$ and PM_{10} concentrations and its receptor locations are presented in Table 4.9-9. These values represent the highest concentrations for each intersection. As shown in the table, all of the pollutant concentrations at the receptors for each of the five study intersections analyzed for the Stoughton Electric Alternative are well below (in compliance with) the NAAQS. As indicated in Section 4.9.2, the study intersections presented in Table 4.9-9 represent the intersections that would incur the greatest impact from the train stations and rail lines associated with the Stoughton Electric Alternative. Since the emissions at these intersections, which represent the worst case scenario (i.e. highest volumes and delays), are well below the NAAQS standards it is expected that the remainder of the study area for the Stoughton Electric Alternative would also fall below (in compliance with) the NAAQS.

4.9.3.4 Stoughton Diesel Alternative

The Stoughton Diesel Alternative is identical to the Stoughton Electric Alternative with the exception of the locomotive power source. Table 4.9-10 presents a summary of the mesoscale (regional) analysis for the Stoughton Diesel Alternative. Similar to the Stoughton Electric, the mesoscale analysis represents travel from South Station to the southern end points of New Bedford and Fall River. The estimated reduction in average number of vehicle miles traveled per day is approximately 240,000 with the implementation of the Stoughton Diesel Alternative. The estimated reduction in VMT as well as the reductions in the concentrations of pollutants is greater with the electric alternative (approximately 16,000 more). This is partially due to the greater estimated time savings experienced with the electric alternative over the diesel alternative. This time savings makes the electric alternative more attractive and thus shifts more people onto the train and out of motor vehicles. This results in greater reduction in VMT and associated air pollutants for the electric alternative compared to diesel.

Table 4.9-10 Mesoscale Mobile Source Analysis Results, Stoughton Diesel Alternative

	Units	2030 No-Build	2030 Build	Build/No-Build Difference
Vehicle Miles Traveled (VMT)[1]	Average Miles/day	118,897,192	118,656,844	-240,348
Volatile Organic Compounds (VOCs)	Kg/day	22,200	22,160	-40
Nitrogen Oxides (NO_x)	Kg/day	19,256	19,210	-46
Particulate Matter 10 (PM_{10})	Kg/day	3,240	3,241	1
Particulate Matter 2.5 ($PM_{2.5}$)	Kg/day	1,490	1,491	1
Carbon Monoxide (CO: Winter)	Kg/day	1,050,356	1,048,400	-1,956
Carbon Dioxide (CO_2)[1]	Tons/year	24,717,339	24,688,173	-29,166

1 The CO_2 was calculated assuming an annualization factor of 365 days/year and 1000kg/1 ton.

Table 4.9-11 summarizes the microscale (local) analysis results for the Stoughton Diesel Alternative. The microscale analysis for Stoughton Diesel Alternative also takes into account the emissions from the trains at the study receptors in the vicinity of the study intersections. Even with the train emissions taken into account, all pollutant concentrations under the Stoughton Diesel Alternative are well below (in compliance with) the NAAQS.

4.9.3.5 Whittenton Electric Alternative

The Whittenton Electric Alternative is a variant of the Stoughton Electric Alternative alignment described in Section 4.9.3.3. At Raynham Junction, the route would divert to the southwest, following the out-of-service Whittenton Branch. This alignment would connect with the Attleboro Secondary at Whittenton Junction in Taunton, and then continue on toward the southeast to connect with the New Bedford Main Line at Weir Junction. The southernmost portion of the Stoughton Line (from Raynham Junction to Weir Junction) and the northwestern-most portion of the Attleboro Secondary (from the Attleboro Bypass to Whittenton Junction), would not be used if this alternative is selected. This evaluation focuses on the Whittenton Branch component.

Table 4.9-12 presents a summary of the mesoscale (regional) analysis for the Whittenton Electric Alternative. The mesoscale analysis represents travel from South Station all the way to the southern end points of Whale's Tooth and Battleship Cove. The difference in VMT between the No-Build and the Whittenton Electric Alternative is an approximately 201,000 reduction with the implementation of the Whittenton Electric Alternative. This VMT reduction results in a reduction in emissions of the analyzed pollutants as well.

Table 4.9-13 summarizes the microscale (local) analysis results for the Whittenton Electric Alternative stations. As shown in the table, under the Whittenton Electric Alternative all of the pollutant concentrations are well below (in compliance with) the NAAQS.

Table 4.9-12 Mesoscale Mobile Source Analysis Results, Whittenton Electric Alternative

	Units	2030 No-Build	2030 Build	Build/No-Build Difference
Vehicle Miles Traveled (VMT)[1]	Average Miles/day	118,897,192	118,695,960	-201,232
Volatile Organic Compounds (VOCs)	Kg/day	22,200	22,170	-30
Nitrogen Oxides (NO_x)	Kg/day	19,256	19,169	-88
Particulate Matter 10 (PM_{10})	Kg/day	3,240	3,240	0
Particulate Matter 2.5 ($PM_{2.5}$)	Kg/day	1,490	1,490	0
Carbon Monoxide (CO: Winter)	Kg/day	1,050,356	1,048,554	-1,801
Carbon Dioxide (CO_2)[1]	Tons/year	24,717,339	24,667,849	-49,490

1 The CO_2 was calculated assuming an annualization factor of 365 days/year and 1000kg/1 ton.

4.9.3.6 Whittenton Diesel Alternative

The Whittenton Diesel Alternative is identical to the Whittenton Electric Alternative with the exception of the locomotive power source. Table 4.9-14 presents a summary of the mesoscale (regional) analysis for the Whittenton Diesel Alternative. Similar to the previous alternatives, the mesoscale analysis represents travel from South Station to the southern end points of New Bedford and Fall River. The estimated reduction in average number of VMT per day is approximately 186,000 with the implementation of the Whittenton Diesel Alternative. The estimated reduction in VMT as well as the reductions in the concentrations of pollutants is greater with the electric alternative (approximately

15,000 more). This is partially due to the greater estimated time savings experienced with the electric alternative over the diesel alternative. This time savings makes the electric alternative more attractive and thus shifts more people onto the train and out of motor vehicles. This results in greater reduction in VMT and associated air pollutants for the electric alternative compared to diesel.

Table 4.9-15 summarizes the microscale (local) analysis results for the Whittenton Diesel Alternative stations. Similar to the previous diesel alternative, the microscale analysis for the Whittenton Diesel Alternative also takes into account the emissions from the trains at the study receptors in the vicinity of the study intersections. Even with the train emissions taken into account, under the Whittenton Diesel Alternative all pollutant concentrations are well below (in compliance with) the NAAQS.

Table 4.9-13 Predicted Maximum Pollutant Concentrations, Whittenton Electric Alternative

4.9.3.7 Stations

This section evaluates the potential air quality impacts of train locomotive emissions on receptor locations adjacent to the train stations. A stationary source analysis was not conducted for the train stations because there are no buildings proposed as part of the stations for the South Coast Rail project. The stations would only include a platform. There are some electrical requirements for each station but the emissions related to the minimal electrical requirements are considered negligible. The air quality analysis evaluated the potential for impact of train locomotives on residential receptor locations adjacent to the train stations by calculating the worst-case pollutant concentrations and the distance from the train stations that they would occur. The trains that would be used on the South Coast Rail alternatives could be electric or diesel. The electric trains do not emit air pollutants and would not have any air quality impacts on receptor locations adjacent to the train stations. An analysis of the impacts of the diesel commuter rail trains on the closest residential area adjacent to the train stations was conducted using USEPA's AERMOD air dispersion model. The primary pollutants of concern from diesel trains are CO, NO_x, PM_{10}, and $PM_{2.5}$. AERMOD calculated the highest concentrations of each pollutant and the distances from the train station that they would occur. These results represent a worst-case condition.

The result of the air quality analysis demonstrates that all of the pollutant concentrations would be below the NAAQS. Receptor locations that are located further away from the train stations would experience lower pollutant concentrations due to additional dilution with greater distances. The worst-case modeling results, distances from the train stations, background, project contributions, and total concentration values are presented in Table 4.9-16. The air quality analysis represents a worst-case condition because it was conducted for 2016. While train emissions do not change frequently, it is reasonable to assume that by 2030 the train emissions and pollutant concentrations presented in Table 4.9-16 would be lower. It should be noted that the pollutant increases from train locomotives are relatively small.

Table 4.9-16 2016 Station Concentrations ($\mu g/m^3$)

Pollutant	Averaging Time	NAAQS (ug/m^3)	Distance from Emission Source (ft)	Background Concentrations (ug/m^3)	Project Contribution (ug/m^3)	Maximum Concentrations (ug/m^3)
CO	1-Hour	40,000	164	3,428.6[1]	367.0	3,795.6
	8-hour	10,000	328	2,400.0[2]	206.5	2,606.5
NO_x	Annual	100	492	44.8	1.1	45.9
PM_{10}	24-Hour	150	328	45.7	0.7	46.4
$PM_{2.5}$	24-Hour	35	328	29.7	0.7	30.4
	Annual	15	492	11.7	0.0	11.7

1 1-hr CO background concentration 3.0 ppm = 3,428.6 ug/m^3
2 8-hr CO background concentration 2.1 ppm = 2,400.1 ug/m^3

4.9.3.8 Layover Facilities

This section evaluates the potential air quality impacts of train locomotive emissions on receptor locations adjacent to the layover facilities. The layover facilities would be open air storage areas for the trains. There are some electrical requirements for each layover facility but the emissions related to the minimal electrical requirements are considered negligible. The air quality analysis evaluated the potential for impact of train locomotives on residential receptor locations adjacent to the layover

facilities by calculating the worst-case pollutant concentrations and the distance from the train stations that they would occur. The trains that would be used on the South Coast Rail alternatives could be electric or diesel. Electric trains do not emit air pollutants and would not have any air quality impacts on receptor locations adjacent to the layover facilities. An analysis of the impacts of the diesel commuter rail trains on the closest residential area adjacent to the layover facilities was conducted using USEPA's AERMOD air dispersion model. The primary pollutants of concern from diesel trains are CO, NO_x, PM_{10}, and $PM_{2.5}$. AERMOD calculated the highest concentrations of each pollutant and the distances from the layover facility that they would occur. These results represent a worst-case condition for both the Wamsutta and Weaver's Cove East layover facilities.

The result of the air quality analysis demonstrates that all of the pollutant concentrations would be below (in compliance with) the NAAQS. Receptor locations that are located further away from the layover facilities would experience lower pollutant concentrations due to additional dilution with greater distances. The worst-case modeling results, distances from the layover facilities, background, project contributions, and total concentration values are presented in Table 4.9-17. It should be noted that the pollutant increases from train locomotives are small. Under the Stoughton Diesel or Whittenton Diesel Alternatives, plug-ins and electric block heaters would be used at the rail layover facilities to minimize criteria pollutant emissions.

Table 4.9-17 2016 Layover Concentrations (μg/m³)

Pollutant	Averaging Time	NAAQS (ug/m³)	Distance from Emission Source (ft)	Background Concentrations (ug/m³)	Project Contribution (ug/m³)	Maximum Concentrations (ug/m³)
CO	1-Hour	40,000	164	3,428.6	734.0	4,162.6
	8-hour	10,000	328	2,400.0	413.1	2,813.1
NO_x	Annual	100	492	44.8	2.2	47.0
PM_{10}	24-Hour	150	328	45.7	1.3	47.0
$PM_{2.5}$	24-Hour	35	328	29.7	1.3	31.0
	Annual	15	492	11.7	0.1	11.8

The air quality analysis also calculated the potential GHG emissions from the layover facilities. The GHG emissions are the dominant emission source from diesel trains using electric plug-ins to keep the engines warm on winter nights. For analysis purposes it was assumed that the layover facilities at New Bedford and Fall River can store up to a total of 7 trains combined. The yearly electric consumption for the trains stored at the layover facilities was estimated in kilowatt hours and converted to CO_2 emissions. The results are presented in Table 4.9-18. Train activity at the two layover facilities would result in 1,272 tons of CO_2 emission per year.

Table 4.9-18 Estimated CO_2 Emissions at the Proposed Layover Facilities

	Hours/day	Number of Trains	Kwh	Mwh	Tons of CO_2/year
Layover Facilities	6	7	258	0.258	1,272

4.9.3.9 Analysis of Locomotive Emissions on Adjacent Receptors

This section evaluates the potential air quality impacts of train locomotive emissions on receptor locations adjacent to the train tracks. The air quality analysis evaluated the potential for impact of train

locomotives on adjacent residential receptor locations by calculating the worst-case pollutant concentrations and the distance from the train track that they would occur. The trains that would be used on the South Coast Rail alternatives could be electric or diesel. The electric trains do not emit air pollutants and would not have any air quality impacts on receptor locations adjacent to the train tracks. An analysis of the impacts of the diesel commuter rail trains on the closest residential area adjacent to the train tracks was conducted using USEPA's AERMOD air dispersion model. The primary pollutants of concern from diesel trains are CO, NO_x, PM_{10}, and $PM_{2.5}$. AERMOD calculated the highest concentrations of each pollutant and the distances from the train tracks over which they would occur. These results represent a worst-case condition.

The results of the air quality analysis demonstrate that all of the pollutant concentrations would be below (in compliance with) the NAAQS. Receptor locations that are located further away would experience lower pollutant concentrations due to additional dilution with greater distances. The worst-case modeling results, distances from the train tracks, background, project contributions, and total concentration values are presented in Table 4.9-19. The emissions from train locomotives initially rise above the train engine due to the high exit temperatures and flow rate out of the exhaust. The emissions are subsequently carried away from the train track and gradually fall to the ground. The air quality analysis calculated the pollutant concentrations at various distances from source and sorted for the highest concentrations at the location that it would occur. Pollutant concentrations closer to the train tracks would be lower or zero depending upon the initial exhaust plume rise and rate that the train locomotive emissions fall to the ground. It should be noted that the pollutant concentration increases from train locomotives emissions are very small. These increases represent 1.5 percent or less of the worst-case total concentrations and would not result in any air quality impacts on receptor locations adjacent to the train tracks.

Table 4.9-19 2016 Train Track Concentrations (µg/m^3)

Pollutant	Averaging Time	NAAQS (ug/m^3)	Distance from Emission Source (ft)	Background Concentrations (ug/m^3)	Project Contribution (ug/m^3)	Maximum Concentratio ns (ug/m^3)
CO	1-Hour	40,000	164	3,428.6	7.65	3,436.25
	8-hour	10,000	328	2,400.0	4.30	2,404.30
NO_x	Annual	100	492	44.8	0.56	45.36
PM_{10}	24-Hour	150	328	45.7	0.33	46.03
$PM_{2.5}$	24-Hour	35	328	29.7	0.33	30.03
	Annual	15	492	11.7	0.01	11.71

4.9.3.10 Microscale Sensitive Area Analysis

This section evaluates the potential for aerial deposition of oxides of nitrogen (NO_X) from train-generated emissions on environmentally sensitive areas (such as the Hockomock Swamp and other wetlands adjacent to the train tracks). The air quality analysis evaluated the potential for impact of train locomotives on adjacent environmentally sensitive areas by calculating the worst-case pollutant concentrations and the distance from the train track that they would occur. The primary pollutant of concern from diesel trains passing through these environmentally sensitive areas is oxides of nitrogen (NO_X). USEPA's AERMOD air dispersion model was used calculate the worst-case concentrations of NO_X.

The air quality analysis demonstrates that the aerial deposition of train-generated emissions is not a

substantial source of pollution of water resources (wetlands) because of the very low concentrations of pollutants in the vicinity of the train track. The NAAQS annual arithmetic mean of NO_X is 100 $\mu g/m^3$. The air quality analysis calculated a worst-case concentration of NO_X 45.8 $\mu g/m^3$ at a distance of 500. The background component is 44.8 $\mu g/m^3$ and the project contribution is 1.0 $\mu g/m^3$. The pollutant increases from train locomotives are very small. These increases represent 2 percent or less of the worst-case total concentrations.

The air quality analysis demonstrates that the aerial deposition of train-generated emissions is not a significant source of pollution of water resources because of the very low concentrations of pollutants in the vicinity of the track. The train-generated emissions would be lower at distances further away from the train tracks and would be reduced in the future with the use of cleaner fuels. The electric trains would have no appreciable air quality impact on environmentally sensitive receptors, such as the Hockomock Swamp and other wetlands, since they do not emit any NO_X.

4.9.4 Temporary Construction–Period Impacts

4.9.4.1 Construction Activities

Temporary air quality impacts could result from construction activities associated with utility relocation, grading, excavation, track work and installation of systems components. Such impacts may occur in residential areas and at other sensitive land uses located within several hundred feet of the alignment. In addition to direct emissions of criteria pollutants and greenhouse gases by construction equipment and construction worker travel, particulate emissions from construction sites can occur due to fugitive dust. Construction best management practices, including dust control measures, outlined in the following section can reduce these impacts and help ensure air quality standards are not exceeded.

4.9.4.2 Construction Mitigation

In an effort to reduce criteria pollutants and GHG emissions from temporary construction activities, construction contractors would be contractually required to adhere to all applicable regulations regarding control of construction vehicles emissions. This would include, but not be limited to, maintenance of all motor vehicles, machinery, and equipment associated with construction activities and proper fitting of equipment with mufflers or other regulatory-required emissions control devices. Also, the prohibition of excessive idling of construction equipment engines would be implemented, as required by MassDEP regulations in 310 CMR 7.11.

Construction specifications would stipulate that all diesel construction equipment used on-site would be fitted with after-engine emission controls such as diesel oxidation catalysts (DOCs) or diesel particulate filters (DPFs).[16] Construction contractors would be required to utilize ultra-low sulfur diesel fuel for all off-road construction vehicles as an additional measure to reduce air emissions from construction activities. Idling restriction signs would be placed on the premises to remind drivers and construction personnel of the State's idling regulation, which requires that the engine must be shut down if the vehicle will be stopped for more than five minutes (310 CMR 7.11(1)(b)).[17]

The contractor would be required to implement protective measures around the construction and demolition work to protect pedestrians and prevent dust and debris from leaving the site or entering the surrounding community. Dust generated from earthwork and other construction activities like

[16] This is consistent with the Certificate of Construction Equipment Standard Compliance Form required for all bids to the MBTA.
[17] http://www.epa.gov/region1/topics/air/sips/ma/MA_Reg11.pdf

stockpiled soils would be controlled by spraying with water to mitigate wind erosion on open soil areas. Other dust suppression methods would be implemented to ensure minimization of the off-site transport of dust. Regular sweeping of the pavement of adjacent roadway surfaces would be required during the construction period to minimize the potential for vehicular traffic to create airborne dust and particulate matter.

4.9.5 Summary of Impacts by Alternative

All alternatives comply with the Clean Air Act Amendments (CAAA) and the Executive Office of Energy and Environmental Affairs (EEA) policy on Greenhouse Gas emissions. The ozone mesoscale analysis demonstrated that the Build Alternatives would result in a decrease of VOC and NO_X emissions, as compared to the No-Build Alternative.

The alternatives would incorporate reasonable and feasible mitigation measures (as described in Chapter 4.1, *Transportation*) to reduce CO_2 and greenhouse gas (GHG) emissions consistent with DEP guidelines. All Build Alternatives meet the EEA policy on GHG emissions because they include mobile and stationary source mitigation measures that would reduce the GHG emission from levels expected from a project without mitigation.

The air quality study demonstrates that all alternatives conform to the CAAA and to the EEA GHG policy because:

- They would implement reasonable and feasible emission reduction mitigation measures.
- No new violation of the NAAQS would be created.
- No increase in the frequency or severity of any existing violations would occur.
- No delay in attainment of any NAAQS would result.

The following provides a summary of the air quality impacts of each of the South Coast Rail alternatives.

4.9.5.1 Mesoscale Analysis Results

The air quality study included a mesoscale analysis that estimates the area wide emissions of VOCs, NO_X, CO_2, CO, and PM emissions. The mesoscale analysis evaluated the changes in emissions based upon changes in the average daily traffic volumes, roadway lengths, and vehicle emission rates. To demonstrate compliance with the USEPA criteria, the air quality study must show the proposed South Coast Rail project's change in daily (24-hour period) VOC and NO_X emissions. Using USEPA recommended air quality modeling techniques, total pollutant emissions were calculated for the No-Build Alternative and the Build Alternatives. The mesoscale analysis calculated the 2035 mobile source emissions from the major roadways in the study area as well as train emissions.

The No-Build Alternative VOC and NO_X emissions are typically lower than the Existing Conditions emissions due to the implementation of state and federal emission control programs, such as the Federal Motor Vehicle Emission Control Program, the Stage II Vapor Recovery System, and the Massachusetts Inspection and Maintenance program. Table 4.9-20 presents the mesoscale analysis results for all the alternatives.

All Build Alternatives would reduce emissions of $NO_{X,}$, CO, and CO_2, in comparison to the No-Build

Alternative (See Table 4.9-20). All of the Build Alternatives have a negligible effect on particulate matter emissions. The electric alternatives all have lower emissions than the corresponding diesel alternative for all of the pollutants. The difference between the diesel and electric is most notable with the NO_X emissions where the emissions for the electric alternative are substantially less than the corresponding diesel alternative. This is due to the higher NO_X output related to the locomotives burning diesel fuel. The Stoughton Electric Alternative generally results in the greatest reduction in emissions which is consistent with the estimated highest reduction in VMT.

Transit Emissions

Feeder Bus System

A review of the feeder bus system that could be provided with the Stoughton Electric and Whittenton Electric Alternatives was conducted. Three regional transit authorities, Brockton Area Transit Authority (BAT), SRTA, and GATRA currently provide local bus service to the SCR corridor. Most of the feeder bus routes that would serve each of the proposed stations are diversions of existing routes. Based on this, it is anticipated that the feeder buses would further reduce greenhouse measures because the overall greenhouse emissions of the bus diversions would be outweighed by the VMT saving of the riders of the feeder bus system. This GHG savings, however, would be negligible compared to the overall GHG savings realized by the proposed Stoughton Electric or Whittenton Electric Alternatives. Because most of the feeder buses would be diversions of existing routes (adding approximately 22.5 miles for all the routes serving the South Coast Rail stations), it is not anticipated that a new fleet would be required to provide the feeder bus system. The existing fleet would be commissioned. It is likely that as the fleets of the various transit providers that provide feeder buses to the stations are replaced, alternative fuels would be considered for replacement.

Transit Vehicles

In addition to the assessment of auto and truck emissions related to the South Coast Rail project, the emissions related to transit systems within the study area for the No-Build Alternative, the Stoughton Electric and Whittenton Electric Alternatives were evaluated and are included in the totals shown in Table 4.9-20. The emissions savings of the replacement of the transit vehicles (No-Build TSM option) with the proposed South Coast Rail electric trains are minimal compared to the overall project emission savings (savings from the reduced VMT). The transit vehicle emission savings are the same for Stoughton and Whittenton Electric Alternatives. The transit VMT is expected to be reduced by 3,700 transit vehicles per day with replacing the transit vehicles with the electric rail which is 0.003 percent of the overall VMT for the study alternatives. This VMT equates to a savings of 6 kg/day of CO, 42 kg/day of NO_x, and 2,800 tons per year of CO_2.

Table 4.9-20 Summary of the 2035 Mesoscale (Regional) Air Quality Analysis for the South Coast Rail Alternatives

		Vehicle Miles Traveled (VMT)[1]	Volatile Organic Compound (VOC) (kg/day)	Oxides of Nitrogen (NO_x) (kg/day)	Particulate Matter 10 (PM_{10}) (kg/day)	Particulate Matter 2.5 ($PM_{2.5}$) (kg/day)	Carbon Monoxide (CO-Winter) (kg/day)	Carbon Dioxide (CO_2) (tons/year)
No-Build	Total	118,897,192	22,200	19,256	3,240	1,490	1,050,356	24,717,339
Stoughton Electric	Total	118,641,260	22,160	19,159	3,240	1,490	1,048,074	24,656,479
	Difference from No-Build	-255,932	-40	-98	0	0	-2,281	-60,859
Stoughton Diesel	Total	118,656,844	22,160	19,210	3,241	1,491	1,048,400	24,688,173
	Difference from No-Build	-240,348	-40	-46	1	1	-1,956	-29,166
Whittenton Electric	Total	118,695,960	22,170	19,169	3,240	1,490	1,048,554	24,667,849
	Difference from No-Build	-201,232	-30	-88	0	0	-1,801	-49,490
Whittenton Diesel	Total	118,710,886	22,170	19,227	3,241	1,491	1,048,908	24,703,175
	Difference from No-Build	-186,306	-30	-29	1	1	-1,448	-14,164

1 VMT represents the vehicle miles traveled on an average weekday in 2035.
2 The Build Alternatives used for the air quality analysis include the physical and operational mitigation proposed to improve traffic operations (as outlined in Chapter 4.1, *Transportation*).
Note: Includes transit-related emissions changes (bus and rail).

4.9.5.2 Microscale Analysis Results

The air quality analysis evaluated the potential for impact of motor vehicles and train locomotives on hotspot locations around stations. Hotspot locations are typically congested intersections. USEPA guidelines require that the project intersections be ranked by their level-of-service and their total traffic volumes and that the air quality analysis model the highest three intersection in each ranking. The intersections in the study area were ranked based on traffic volumes and level of service. In order to ensure adequate coverage of the study area, additional intersections were added, one for each station site that would be impacted by station-related traffic. The microscale analysis included motor vehicle and train emissions to calculate worst-case concentrations.

The trains that would be used on the Build Alternatives could be electric or diesel. The electric trains do not emit air pollutants and would not have any contribution to air quality impacts on receptor locations around the stations. The microscale analysis, which typically focuses on motor vehicle emissions, added the emissions of the diesel commuter rail trains to the intersection receptor locations to calculate the highest concentrations of CO, PM_{10}, and $PM_{2.5}$. The results represent a worst-case condition. All of the pollutant concentrations are below (in compliance with) the NAAQS. The Build Alternatives would not substantially change any of the concentrations of CO, PM_{10}, and $PM_{2.5}$. All of the increases are less than 1ppm for CO and less than 0.3 $\mu g/m^3$ for PM_{10} and $PM_{2.5}$.

The results demonstrate that all alternatives would meet the NAAQS for CO, PM_{10}, and $PM_{2.5}$. The worst-case modeling results are presented in the tables in Section 4.9.3. The alternatives would not:

- cause any new violation of the NAAQS;
- increase the frequency or severity of any existing violations; or
- delay attainment of any NAAQS.

4.9.5.3 Greenhouse Gas Emissions

The Executive Office of Energy and Environmental Affairs (EEA) has developed a policy that requires project proponents to identify and describe the feasible measures to minimize GHG emissions. The Policy requires that projects quantify the project's direct and indirect GHG emissions and identify measures to avoid, minimize, or mitigate such emissions. Projects generate GHG emissions through the use of electricity and fossil fuels typically from building sources including boilers, heaters and internal combustion engines. EEA/MEPA's GHG policy requires that the analysis include a no-build, build, and build with improvements conditions. The build condition represents the stationary source emissions that would occur if the proposed Project were to be built using typical construction materials and rooftop equipment that are built to the Massachusetts Building Code. The build with improvements condition should include improved building materials and rooftop equipment, and renewable resources, such as solar, wind, geothermal, green power, and energy star measures.

While the alternatives would help reduce GHG emissions, there would be no buildings associated with the alternatives that would generate GHG emissions. The stations and layover facilities would all be open to the outside and would not need heating/air conditioning equipment. Therefore, the air quality analysis did not evaluate cumulative impacts by alternative, nor did it compare building under the current state building codes to proposed building with mitigation measures. Because no buildings are associated with any of the alternatives, no discussion and consideration of recommendations of the

Massachusetts Zero New Energy Building Task Force was included. In absence of buildings associated with the alternatives the air quality analysis did not include an evaluation of renewable energy sources and commitment to appropriate LEED and Energy Star elements.

The air quality analysis did evaluate the motor vehicle and train locomotive GHG emissions and did discuss a commitment to using train engine plug-ins and electric block heaters at layover facilities. All Build Alternatives represent a GHG mitigation measure because they are all designed to reduce vehicle miles of travel. All Build Alternatives would reduce GHG emissions as compared to the No-Build conditions. The GHG emission results by alternative are presented in Section 4.9.3. A discussion of GHG is also included in Chapter 5.

Indirect Effects

The mobile source CO_2 emissions indirectly resulting from the No-Build Alternative would be 74,676 tons per year (tpy). For the Stoughton Electric Alternative as compared to the No-Build Alternative, mobile source GHG emissions would be reduced as a result of reductions in VMT. The Stoughton Electric Alternative would indirectly result in 74,482 tpy CO_2 emissions, a reduction of 194 tpy. The total indirect changes in GHG emissions from mobile and stationary sources would be an increase of 32, 974 tpy over the No-Build Alternative for the Stoughton Electric Alternative. For the Whittenton Electric Alternative as compared to the No-Build Alternative, mobile source GHG emissions would be reduced as a result of reductions in VMT. The Whittenton Electric Alternative would indirectly result in 74,516 tpy CO_2 emissions, a reduction of 160 tpy. The total indirect changes in GHG emissions from mobile and stationary sources would be an increase of 33,008 tpy over the No-Build Alternative for the Whittenton Electric Alternative.

4.9.5.4 Air Toxics

The air quality study qualitatively evaluated the potential for impact due to air toxics, as required in The Secretary of Environmental Affairs Certificate on the Environmental Notification Form (ENF). Most air toxics originate from human-made sources, including on-road mobile sources, non-road mobile sources (e.g., airplanes), area sources (e.g., dry cleaners) and stationary sources (e.g., factories or refineries).

Mobile sources emit “hazardous air pollutants” or air toxics that can cause cancer and other serious health effects. The Clean Air Act provided an initial list of 188 hazardous air pollutants, 93 of which USEPA has identified as being emitted by mobile sources.[18] The Clean Air Act also required USEPA to conduct research on human health effects of air toxics and prescribed the approach to setting emissions standards and other regulatory requirements to control air toxic emissions. Specific to mobile sources, Section 202(l)(2) of the Clean Air Act requires USEPA to set emission standards to control air toxics from motor vehicles and motor vehicle fuels. Unlike the criteria pollutants for which NAAQS are established, the Clean Air Act did not grant USEPA the authority to establish health-based ambient air quality standards for MSATs. As part of the 2007 Control of Hazardous Air Pollutants from Mobile Sources rule, USEPA identified seven compounds with substantial contributions from mobile sources that are among the national and regional-scale cancer risk drivers from their 1999 National Air Toxics Assessment (NATA). These are acrolein, benzene, 1,3-butadiene, diesel particulate matter plus diesel exhaust organic gases (diesel PM), formaldehyde, naphthalene, and polycyclic organic matter (POM).

For each alternative, the amount of MSATs emitted would be proportional to the VMT, assuming that

[18] U.S. Environmental Protection Agency. *Final Rule, Control of Hazardous Air Pollutants from Mobile Sources*, 72 F.R. 8427, February 26, 2007.

other variables such as fleet mix are the same for each alternative. The VMT for each alternative are presented above in Table 4.9-20. The VMT estimated for each of the Build Alternatives are lower than that for the No-Build Alternative, because any of the South Coast Rail alternatives would remove vehicles (and therefore reduce VMT) from the study area roadways by shifting mode choice to public transportation (i.e. the South Coast Rail). This reduction in VMT would lead to lower MSAT emissions for the Build Alternatives. The differences in VMT between the various alternatives would result in similar differences in the MSAT emissions.

Based on an FHWA analysis using USEPA's MOVES2010b model even if national VMT increases by 102 percent as assumed from 2010 to 2050, a combined reduction of 83 percent in the total annual emissions for the priority MSAT is projected for the same time period.[19] Local conditions may differ from these national projections in terms of fleet mix and turnover, VMT growth rates, and local control measures. However, the magnitude of the USEPA projected reductions is so great (even after accounting for VMT growth) that MSAT emissions in the study area are likely to be lower in the future in all cases.

4.9.6 Regulatory Compliance

4.9.6.1 MassDEP Air Quality Regulations

All of the pollutant concentrations at the receptors for all study intersections analyzed for the Stoughton Electric and Whittenton Electric Alternatives are well below (in compliance with) the MassDEP ambient air quality standards (310 CMR 6.0) for PM10 and CO which follow the USEPA guidelines under 40 CFR part 50. The South Coast Rail project would also follow all MassDEP regulations outlined in 310 CMR 7.0. The project would include the following (but not limited to):

- reduce single occupant commuter vehicle use;
- reduce overall emissions with the reduction of VMT; and
- require implementation of low sulfur fuel use on all construction vehicles.

4.9.6.2 General Conformity

As noted in Section 4.9.1.2, the South Coast Rail project is subject to General Conformity (Title 40 Code of Federal Regulations (CFR) Part 93, Subpart B). General conformity provisions only apply in nonattainment and maintenance areas. The project area is nonattainment for the 8 -hour ozone standard, therefore the relevant pollutants for consideration are the two ozone precursors- VOCs and NO_x. As a regional issue, microscale analysis is not applicable to ozone precursors. The long-term effect of the Stoughton and Whittenton Alternatives on VOC and NO_x emissions is beneficial (e.g. reduced emissions relative to the No-Build Alternative). Therefore, a conformity determination would not be required to address long-term operational emissions, even if such emissions could be practically controlled by the Corps. As discussed in Section 4.9.1.2, long-term operation emissions (such as from diesel locomotives under the diesel Build Alternatives), are not indirect emissions within the scope of General Conformity because the Corps cannot control them and has no continuing program control over the rail line.

However, General Conformity also applies to peak year construction emissions (unlike transportation conformity that exempts consideration of construction emissions if construction activities last less than

[19] http://www.fhwa.dot.gov/environment/air_quality/air_toxics/policy_and_guidance/aqintguidmem.cfm

five years in any one location). For the SCR project, construction-related emissions are a reasonably foreseeable consequence of the Corps' Section 404 permit decision. If construction emissions exceed certain de minimis criteria, a General Conformity determination could be required. The de minimis criteria for this project (ozone nonattainment area in an ozone transport region) are as follows:

- VOC- 50 tons/year
- NO_x- 100 tons/year

The construction schedule and staging of the Build Alternatives have not been defined in sufficient detail at this point in the development of the project to quantify construction period VOC and NO_x emissions for comparison to the de minimis criteria. The Corps would require the preparation of a General Conformity applicability analysis for peak construction year emissions of the preferred alternative prior to the NEPA Record of Decision. If the *de minimis* criteria are not exceeded, no further review would be required. If the criteria are exceeded, a General Conformity determination (including 30-day public review period) would be required prior to project implementation.

South Coast Rail Coordination

Ridership and traffic estimates associated with each alternative were developed and calibrated by the Central Transportation Planning Staff (CTPS) using its Regional Travel Demand Model (RTDM). The inputs for the RTDM included land use assumptions, transportation service assumptions, and modeling methods. The RTDM and the subsequent analysis were developed from information provided by and coordinated with various federal, state, regional, and local entities. Many parts of the model used in this analysis were examined and accepted by FTA as part of various New Starts and Environmental Review documents. The State of Rhode Island provided information to CTPS on the Rhode Island RTDM, including land use assumptions, and specific projects such as the TF Green Rail project. CTPS coordinated with the state of Massachusetts to ensure that utilized data was consistent across state agencies such as MassDOT and the MBTA in developing service plans. The Metropolitan Area Planning Council (MAPC), the Old Colony Planning Council (OCPC), and the Southeastern Regional Planning & Economic Development District (SRPEDD) provided information to CTPS as used in their last adopted Regional Long Rang Transportation Plan. This information generally consisted of land use assumptions, transit system details, and highway characteristics; both present and future. Local communities provided CTPS with information regarding details on where the stations would be located, the amount of parking that could be built, as well as other service characteristics. CTPS coordinated with the parties above and others in establishing appropriate planning assumptions for its Regional Travel Demand Model (RTDM).

4.10 PROTECTED OPEN SPACE AND AREAS OF CRITICAL ENVIRONMENTAL CONCERN

4.10.1 Introduction

This chapter describes existing conditions and analyzes potential impacts on protected open space and state-designated ACECs. Although not subject to regulatory jurisdiction, important privately owned conservation lands adjacent to each alternative are also included, where applicable. An overview is presented below of the definition of the resources, their regulatory context and the methodology used to inventory the resources and evaluate potential impacts. Section 4.10.2 identifies the project study area, summarizes regional public or private open space and ACEC resources, and describes the protected public and selected private open space and ACECs along each alternative alignment. Section 4.10.3 identifies the effects to protected open space or designated ACECs that may result from implementing each of the South Coast Rail alternatives, and describes potential mitigation measures that may be implemented to offset direct impacts to protected open spaces and ACECs. A summary of the regulatory programs that address protected open spaces and ACECs is provided in Section 4.10.4.

The Secretary of the EEA issued a certificate on the ENF on April 3, 2009. The certificate included a number of requirements that defined the scope of the DEIR. Specific requirements for protected open spaces and ACECs were:

- "The DEIR should identify ecosystems within each ACEC and conservation area that would be impacted by the various alternatives, and include a quantitative and qualitative analysis of impacts to wetlands and water quality, wildlife habitat, water supply, and floodplain."

- "The DEIR should include a detailed analysis of the proposed disposition [of DCR property in the Blue Hills Reservation], which should include a quantitative and qualitative description of potential land impacts, a map showing the area that would require a disposition, and a demonstration of how the disposition would comply with the EOEEA's Article 97 Land Disposition Policy. The DEIR should include an evaluation of feasible alternatives to the disposition. The DEIR should also identify and describe any other potential impacts to DCR property."

- "The DEIR should include a detailed analysis of the potential impacts of project alternatives on the Hockomock Wildlife Management Area and other protected open space. The DEIR should identify all Article 97 lands that would be impacted by the alternatives, clarify if state or municipality owned, describe potential impacts and, where applicable, discuss consistency with EOEEA's Article 97 Land Disposition Policy."

The Secretary's Certificate on the DEIR, dated June 29, 2011, included the following requirements for the FEIR in regard to open space:

- "*Hockomock Swamp Wildlife Management Area*. The proposed Stoughton route uses an inactive railroad Right-of-Way that crosses through the Hockomock Swamp [Wildlife Management Area]. The FEIR should include a detailed analysis of the project's potential impacts to open space within the Hockomock Swamp, including any impacts relating to infrastructure, such as access roads for construction or ongoing maintenance of the trestle and rail ROW. The FEIR should include a detailed plan to avoid and minimize impacts and/or

to mitigate unavoidable impacts to open space. The FEIR should clarify whether proposed work falls within the existing ROW or to what degree it will extend beyond it."

- "*Taunton Wild and Scenic River*. The FEIR should include an update on consultations with the National Park Service regarding the status of Taunton River as a National Wild and Scenic River, and to discuss issues relating to water quality impacts from construction and stormwater runoff, rail line crossings of the Taunton and its tributaries, impacts to natural and cultural landscape features, selection and siting of layover facilities, and construction of the Fall River Depot station."

- "*Acushnet Cedar Swamp National Natural Landmark*. The FEIR should describe proposed measures to avoid and minimize construction and train operational noise impacts during critical wildlife breeding season in spring and early summer."

- "*Article 97 and other Open Space*. The open space impact estimates presented in the DEIR's summary tables are limited to Article 97 land and are not representative of the full range of potential impacts to open space. The FEIR should quantify all open space impacted by the project and describe mitigation commitments. The FEIR should expand upon the evaluation in the DEIR/S to demonstrate consistency with the EEA Article 97 Land Disposition Policy. MassDOT should consult with the Department of Conservation and Recreation during FEIR preparation to discuss policy requirements and a land disposition agreement."

4.10.1.1 Resource Definition

Protected public open space includes public parks, public conservation areas, public recreation areas, and wildlife refuges owned by a public agency, such as the local or state government. Ballfields, athletic fields, or playgrounds associated with public schools have also been included where such resources are publicly accessible. Private open space preserved for conservation and owned by a non-profit land trust, or other similar entity that is available for public use or benefit is also included in the analysis. Public benefit may include activities for the public, such as educational programs or recreation, and/or ecological services provided by the open space, such as wildlife habitat or vital ecosystems. Privately owned recreational facilities such as golf courses are not included.

ACECs are places in Massachusetts that receive special recognition because of the quality, uniqueness, and significance of their natural and cultural resources. These areas are identified and nominated at the community level and are reviewed and designated by the state's Secretary of Environmental Affairs. Under the state program, ACECs are designated to promote awareness and stewardship of these important natural areas, although developed areas may be included within an ACEC's boundaries. The designation works through the existing state environmental regulatory and review framework and does not change local regulations or zoning.[1] The ACEC program is managed by the Massachusetts Department of Conservation and Recreation (DCR).

4.10.1.2 Regulatory Context

Projects within an ACEC that are subject to state agency jurisdiction or regulation requiring a state permit, or are funded by a state agency, are reviewed with close scrutiny to avoid or minimize adverse environmental impacts.[2] The principal state agencies with regulations referring to ACECs are the

[1] DCR. 2009. ACEC Regulatory Summary. Website http://www.mass.gov/dcr/stewardship/acec/reqsum.htm.
[2] Ibid

Massachusetts Office of Coastal Zone Management (CZM), the MEPA Office, and MassDEP. MEPA regulations require that state agencies study the environmental consequences of their actions, including permitting and financial assistance, and take all feasible measures to avoid, minimize, and mitigate damage to the environment.[3] The proponent of any project (as defined by the MEPA regulations) located within an ACEC must file an ENF for MEPA review, unless the project consists solely of one single-family dwelling. The ENF for the South Coast Rail project was filed in November 2008 and the Secretary of the Executive Office of EEA's Certificate[4] on the ENF requires that an EIR be filed.

Article 97 of the Massachusetts Constitution protects all publicly owned lands used for conservation or recreation purposes. This provision protects lands acquired for natural resources values, meaning "conservation, development and utilization of the agricultural, mineral, forest, water, air, and other natural resources."[5] Before these properties can be sold, transferred, or converted to a different use, the following is required: action by the local Conservation Commission and Parks and Recreation Commission; a two-thirds vote by the municipal government; and a roll call two-thirds vote of the State House of Representatives and Senate.

According to the EEA's Division of Conservation Services, conservation and recreation land within a community is protected (also referred to as "in perpetuity") if it is owned by the local Conservation Commission, a state conservation agency, a nonprofit land trust, or if the municipality received state or federal monies for the improvement or purchase of the land.[6] Private property can also be permanently protected if there is a deed restriction, if the land is listed as having an Agricultural Preservation Restriction, or if the MassDEP has placed a restriction on the property for wetland conservation. Typically, land owned by other agencies (such as a municipal Parks and Recreation Commission or the local school system) may not be presumed to be permanently protected.

Publicly owned open space may also be subject to protection under Section 4(f) of the Department of Transportation Act of 1966[7] for any actions undertaken by the Federal Transit Administration, Federal Railroad Administration, or Federal Highway Administration. Section 4(f) of the Act states, "the Secretary of Transportation will not approve any program or project that requires the use of any publicly-owned land from a public park, recreation area, or wildlife and waterfowl refuge of national, state, or local significance or land from an historic site of national, state, or local significance as determined by the officials having jurisdiction thereof, unless there is no feasible and prudent alternative to the use of such land and such program, and the project includes all possible planning to minimize harm resulting from the use."

Section 4(f) resource categories include:

- Public parks;
- Public recreation areas;

[3] MEPA Regulations 301 CMR 11.00. ACECs are specifically addressed at 301 CMR 11.03(11).

[7] United States Department of Transportation Act of 1966, Section 4(f). In 1983, the Act was re-codified and Section 4(f) is now 49 USC, Section 303, "Policy on lands, wildlife and waterfowl refuges, and historic sites."

- Publicly-owned wildlife and waterfowl refuges of national, state, or local significance; and
- Historic sites of national, state, or local significance (including properties listed in or eligible for listing in the National Register of Historic Places and archaeological sites warranting preservation in place).

Playgrounds on public school properties are also considered Section 4(f) public recreation areas if they are publicly owned, open to the public after normal school hours, used for recreation, and are considered a significant recreational resource in the community by the officials having jurisdiction over the resource.

4.10.1.3 Methodology

Available mapping (2005 MassGIS data), supplemented by field visits and information provided by South Coast municipalities, were used to identify, characterize, and map open space and ACECs within 0.25 mile distance of each section of the alternative corridors that is not currently in passenger transportation use. The distance of 0.25 mile was selected as the maximum extent of resource areas that could potentially be affected by the alternatives. Each municipality through which an alternative passes received a letter in December 2008 requesting information on additional public or private open space parcels not identified by MassGIS. The request letters and municipality responses received are provided in Appendix 4.10-A.

4.10.2 Existing Conditions

This section identifies public parks, public conservation areas, public recreation areas, and wildlife refuges (protected open space) and ACECs within 0.25 mile of each proposed alternative. Although not subject to regulatory jurisdiction, important privately owned conservation lands adjacent to each corridor are also identified and described. These open space parcels are described below and depicted in Figures 4.10-3a-d through 4.10-9a-b.

4.10.2.1 Regional Overview

The South Coast Rail project would serve and could impact the following ten communities: Canton, Stoughton, Easton, Taunton, Raynham, Berkley, Lakeville, Freetown, Fall River and New Bedford. South Coast Rail alternative alignments pass through these communities, and new station sites are within or near each. Accordingly, these ten communities constitute the Public Open Space and ACECs study area. Protected public open space, selected private open space, and ACECs within each of these municipalities, relative to the alternative alignments and station sites, are discussed below.

In 2008, just over 18 percent of the South Coast communities'[8] land area was considered permanently protected public open space.[9] Of the ten communities impacted by the Build Alternatives, most of the protected public open space is in Easton and the coastal communities of Fall River and New Bedford, and the towns of Freetown, Lakeville and Taunton. An important permanently protected public area is the Freetown-Fall River State Forest, which includes 5,441 acres of public open space. The southern

[8] This refers to the 27 South Coast communities analyzed in the DEIS/DEIR, not the 10 communities that constitute the Public Open Space and ACEC Study Area in this FEIS/FEIR.

[9] EOT and Massachusetts Office of Housing and Economic Development. 2009. *South Coast Rail Economic Development and Land Use Corridor Plan.* Commonwealth of Massachusetts, Executive Office of Transportation and Office of Housing and Economic Development. Prepared by Goody Clancy: Boston.

coastal communities generally contain more undeveloped land than the northern inland communities within the South Coast region.

Public open space within the study area includes one National Historic Park (New Bedford Whaling National Historic Park), the Freetown-Fall River State Forest, conservation areas, and recreation areas. Recreation areas, both developed parks and natural forested areas, are the most common types of public open space. Although not permanently protected, fields and play areas at public schools within the study area have also been identified.[10]

In addition to the protected public open space properties described below, several properties owned by non-profit and/or non-governmental organizations are located within 0.25 mile of the South Coast Rail corridors. Figure 4.10-1 depicts the major public and private open space and recreation resources.[11]

ACECs in the South Coast Rail study that are either crossed by or adjacent to the Build Alternatives include Canoe River Aquifer, Hockomock Swamp, Three Mile River, and Fowl Meadow and Ponkapoag Bog (Figure 4.10-2).

4.10.2.2 Existing Conditions within the Study Corridor

Southern Triangle (Common to All Build Alternatives)

All Build Alternatives would require improvements to the existing active rail infrastructure south of Weir Junction in Taunton (the New Bedford Main Line and the Fall River Secondary). This section identifies and describes the state-designated ACECs and public parks, public conservation areas, public recreation areas, and wildlife refuges within 0.25 mile of the New Bedford Main Line (Figures 4.10-3a-d) and the Fall River Secondary (Figures 4.10-4a-c). Identified privately owned open space is also described.

Areas of Critical Environmental Concern

No designated ACECs are present in the areas adjacent to the New Bedford Main Line and Fall River Secondary.

Protected Public Open Space

Table 4.10-1 lists all of the identified protected public open space within 0.25 mile from the New Bedford Main Line and the Fall River Secondary. Selected protected public open spaces adjacent to the New Bedford Main Line or the Fall River Secondary are described below.

Howland Road Area—The Howland Road Area[12] is in the southwestern portion of Lakeville (Figure 4.10-3c), adjacent to the New Bedford Main Line and the Assonet Cedar Swamp Wildlife Sanctuary (owned by the Massachusetts Audubon Society and described below). The Town of Lakeville owns the 636-acre parcel surrounding a 560-acre farmland.

[10] Public school fields and play areas are only public if they are open to the general public after hours. This report includes all fields as hours of operation and availability of these resources were not available at the time of this report.

[11] Major public and private open spaces are those that are generally greater than 20 acres and visible at the scale of the figure.

[12] Southeastern Regional Planning and Economic Development District, Town of Lakeville Priority Development and Priority Protection Area Plan, June 2008, page 12.

Table 4.10-1 Southern Triangle Protected Public Open Space

Key: NPS National Park Service; DCR Massachusetts Department of Conservation and Recreation.
R = Recreation; C = Conservation; B = Conservation and Recreation; E = Educational Facility with publicly used recreation facilities; H/C = Historic/Cultural

Acushnet Cedar Swamp State Reservation—The Acushnet Cedar Swamp State Reservation is an approximately 1,000-acre property owned by DCR in New Bedford and Dartmouth, north of the New Bedford Airport and adjacent to portions of the New Bedford Main Line (Figures 4.10-3d). It includes an outstanding example of an Atlantic white cedar swamp and provides habitat for state-listed rare wetlands wildlife and other state-listed rare, endangered, or special concern species. This is one of eight cedar swamps in public ownership in Massachusetts, and has been designated as a National Natural Landmark.[14] The New Bedford Main Line, currently used for freight rail service, forms the eastern boundary of the State Reservation.

[13] Schools have been listed in this report because they contain recreational resources; however, school fields are only considered public open space if they are available to the public after hours. It was not currently possible to confirm this information. Additionally, school properties are not considered protected because they may be sold in the future.

[14] Sorrie, B.A. and H.L. Woolsey, 1987. The Status and Distribution of Atlantic White Cedar in Massachusetts. In A. Laderman, Atlantic White Cedar Wetlands, Westview Press. pp. 135-142.

New Bedford Whaling National Historic Park—The New Bedford Whaling National Historic Park is in downtown New Bedford (Figure 4.10-3d). The park is generally the area between MacArthur Drive, Union Street, Acushnet Avenue, and Kempton Street. Established in 1996 as a National Historic Landmark District, the park's mission is to preserve, protect, and interpret certain districts, structures, and artifacts that are associated with the history of whaling and related social, economic, and environmental themes for the benefit and inspiration of this and future generations. Some of the properties within the boundary of the park are owned by the National Park Service (NPS).

Forge Pond—Forge Pond is the uppermost and largest pond along the Assonet River in Freetown (Figure 4.10-4a). The Fall River Secondary passes through the protected public open space associated with Forge Pond and adjacent to the pond itself. Forge Pond is approximately 4 acres and is managed by the Town of Freetown Board of Selectmen. The protected open space shown on Figure 4.10-4a associated with Forge Pond is accessible only from the water at Forge Pond. The pond's primary purpose is passive recreation and conservation.

Freetown-Fall River State Forest—The Freetown-Fall River State Forest is a 5,441-acre property with access from Slab Bridge Road in Freetown and located along the Fall River Secondary (Figures 4.10-4a-b). The State Forest provides recreational facilities, including a picnic area and 50 miles of unpaved roads and trails used for hiking, mountain biking, horseback riding, and snowmobiling. Hunting and fishing are also popular uses of the State Forest, particularly Rattlesnake Brook, which is stocked with brook trout. The Freetown-Fall River State Forest abuts the existing Fall River Secondary in Freetown. None of the active public recreation areas or trails is adjacent to the Fall River Secondary tracks.

Turner Playground—Turner Playground is a small parcel of approximately 2.4 acres located adjacent to the Fall River Secondary in Fall River (Figure 4.10-4c). The playground is at the intersection of Cherry and Locust Streets. According to the description from the latest Fall River Open Space and Recreation Plan,[15] the playground is in poor condition. The playground contains two lighted basketball courts and one playground.

Fall River Heritage State Park—Fall River Heritage State Park is adjacent to the Fall River Secondary in Fall River Figure 4.10-4c), and is owned and operated by the DCR. The approximately 8.5-acre park overlooks Battleship Cove and is home to the World War II battleship, U.S.S. Massachusetts. The park follows the shore of the Taunton River (Mount Hope Bay) and has a boardwalk, benches, groves of trees, an antique carousel, public sailing programs, and a 3-acre meadow used for summer concerts, craft festivals, and family picnics.[16]

Heritage Park—Owned and managed by the City of Fall River, Heritage Park is separated from Heritage State Park by Route 79. It is adjacent to the Fall River Secondary in Fall River (Figure 4.10-4c) and is approximately 2.7 acres. Heritage Park is used primarily as a neighborhood park, providing green space and walking trails to nearby residents.

Ponta Delgada Plaza—The Ponta Delgada Plaza (also called Gates of the City Plaza) is a 2.2-acre site on Water Street adjacent to the Fall River waterfront and the Fall River Secondary (Figure 4.10-4c); this is the site of the proposed Battleship Cove Station. The site is a rectangular-shaped parcel, currently

[15] Green Futures. 2004. *Open Space and Recreation Plan for the City of Fall River.* Green Futures website accessed at: http://www.greenfutures.org/projects/osp/default.html on January 16, 2009.

[16] DCR. 2009. Fall River Heritage State Park. Website. http://www.mass.gov/dcr/parks/southeast/frhp.htm accessed on January 12, 2009.

owned by the City of Fall River. It contains the Gates of the City, a large triple archway that is a replica of gates in Ponta Delgada, Sao Miguel, Azores, Fall River's sister city. The site also contains parking and a grassed area.

Private Open Space

Private open space located adjacent to the New Bedford Main Line or the Fall River Secondary is briefly described below, based on readily available information.

Assonet Cedar Swamp Wildlife Sanctuary—The Assonet Cedar Swamp Wildlife Sanctuary is a 1,000-acre parcel of conservation land owned by the Massachusetts Audubon Society in southwest Lakeville, near the Berkley and Freetown town lines (Figure 4.10-3b). The New Bedford Main Line passes through the wildlife sanctuary and the Fall River Secondary passes nearby. This property consists largely of the wetlands bordering the Cedar Swamp River south of Myricks Junction. These wetlands include extensive Atlantic white cedar swamps and support numerous state-listed species.

Stoughton and Whittenton Alternatives

This section identifies and describes the state-designated ACECs and public parks, public conservation areas, public recreation areas, and wildlife refuges within 0.25 mile of the Stoughton Electric and Diesel Alternatives (Figures 4.10-5a-e), as well as within 0.25 mile of the Whittenton Electric and Diesel Alternatives (Figures 4.10-6a-b). Identified privately owned open space is also described. In general, protected open space and ACECs adjacent to the Northeast Corridor alignment segment have been excluded from the existing conditions discussion as the Build Alternatives do not include any construction activity along the Northeast Corridor.

Areas of Critical Environmental Concern

The Stoughton and Whittenton Alternatives pass through or near four ACECs: Fowl Meadow and Ponkapoag Bog, Hockomock Swamp, The Canoe River Aquifer, and the Three Mile River Watershed (Figure 4.10-2, Figure 4.10-5a-e and Figures 4.10-6a-b). These resources are described below.

Fowl Meadow and Ponkapoag Bog—The Fowl Meadow and Ponkapoag Bog ACEC, designated in 1992, encompasses approximately 8,350 acres[17] and is located in the metropolitan Boston region, including Boston, Canton, Dedham, Milton, Norwood, Randolph, Sharon, and Westwood. The Northeast Corridor passes through the Fowl Meadow portion of this ACEC from near the Readville Station to near the Canton Junction Station (Figure 4.10-5a). The ACEC is fragmented by several major transportation corridors, including I-95, I-93, Route 24, Route 138, Route 1, and other roadways. It also includes upland areas that are developed commercial and residential lands as well as undeveloped forested upland and farmland.

The central resource features of the Fowl Meadow and Ponkapoag Bog ACEC are the Neponset River and the Ponkapoag Pond and Bog. An 8-mile stretch of the Neponset River and its tributaries, the adjacent wetlands and floodplains, the associated aquifers and public water supplies, and the diverse habitats form the core resources of the Fowl Meadow portion of the ACEC. Ponkapoag Bog and Pond and the natural communities and wildlife habitats form the core resources of the Ponkapoag Bog

[17] DCR. 2013. Fowl Meadow and Ponkapoag Bog. Website: http://www.mass.gov/eea/agencies/dcr/conservation/acec/fowl-meadow-and-ponkapoag-bog.html.

portion of the ACEC. Historical and archaeological resources and the recreational and educational values of both areas support their overall significance to the people and communities of the area.

The Fowl Meadow area includes the largest wetland and floodplain areas in the Neponset River basin. There are several municipal public wells that provide water to the communities of Canton, Dedham, and Westwood. The northern Fowl Meadow area and Ponkapoag Bog have been designated a National Environmental Study Area by the NPS. Approximately 2,330 acres of the ACEC are owned by DCR, and are managed as part of the Blue Hills Reservation.

The Northeast Corridor forms the eastern boundary of the ACEC between Neponset Street in Canton and I-95, and forms the western boundary of the ACEC southwest of the I-95/I-93 interchange. The Northeast Corridor passes through the ACEC north of I-95, where the existing rail line parallels the Neponset River.

Hockomock Swamp ACEC—The Hockomock Swamp ACEC, designated in 1990 includes approximately 16,950 acres[18] in Bridgewater, Easton, Norton, Raynham, Taunton, and West Bridgewater. The ACEC is fragmented by several major transportation corridors, including Routes 24, I-495, 138, 106, other major roadways, and the existing, abandoned MBTA-owned railroad grade/right-of-way and it includes substantial upland areas within the watershed of the Hockomock Swamp. These uplands include developed commercial and residential lands as well as undeveloped forested upland and farmland. The Stoughton and Whittenton alignments pass through the Hockomock Swamp ACEC from near Purchase Street in Easton to Bridge Street in Raynham (Figures 4.10-5c-d), along the aforementioned abandoned MBTA-owned railroad grade/right-of-way.

The Hockomock Swamp and associated wetlands and water bodies are described by DCR as the largest vegetated freshwater wetland system in Massachusetts, with outstanding natural resource qualities. The wetlands, which include Hockomock Swamp, Dead Swamp, Titicut Swamp, and Little Cedar Swamp, serve as the headwaters of the Town River, a tributary of the Taunton River, and overlay a system of high and medium yield aquifers that supply public drinking water through wells in Raynham and West Bridgewater.

The Hockomock Swamp ACEC provides habitat for several species listed as rare, endangered, or of special concern by the NHESP and much of the ACEC is designated as BioMap Core Habitat. The DCR describes the Hockomock Swamp ACEC as one of the most extensive inland wildlife habitats in southeastern Massachusetts. The Atlantic white cedar swamp and acidic fen wetland communities scattered throughout the ACEC are considered to be outstanding examples of these unique natural communities. The ACEC is important for its significant scenic sites.

The Massachusetts Division of Fisheries and Wildlife (DFW) owns approximately 5,000 acres within the Hockomock Swamp. The Hockomock Swamp Wildlife Management Area (WMA) provides public access to the swamp and to several recreational areas. Additional public and nonprofit lands are located within the ACEC. The area is popular for hunting, fishing, boating, canoeing, swimming, and for observing and studying flora and fauna.

The MBTA has continued to own the railroad right-of-way through the WMA and the ACEC from Route 123 in Easton to I-495 in Raynham. This land was acquired by the MBTA from the New York, Hartford

---

[18] DCR. 2009. Hockomock Swamp. Website http://www.mass.gov/dcr/stweardship/acec/acecs/l-hcksmp.htm. Accessed on September 1, 2009.

and New Haven Railroad in 1973 and reserved as a public transportation corridor. Although the right-of-is used as an informal recreation trail, including the use of all-terrain vehicles both on and off the right-of-way, this is not an authorized use, as this is a designated transportation land and cannot be converted to recreational use. The right-of-way is not subject to Article 97 because it is not a public "land or easement taken or acquired for the conservation of forest, water, air, and other natural resources."

Canoe River Aquifer ACEC—The Canoe River Aquifer ACEC, designated in 1991, covers approximately 17,200 acres[19] in Easton, Foxborough, Mansfield, Norton, Sharon, and Taunton. The associated areas within this ACEC include Snake River, Watson Pond, and Lake Sabbatia. As the Whittenton Branch crosses the Raynham-Taunton town boundary, it passes near this ACEC (Figure 4.10-6a).The ACEC is fragmented by several major transportation corridors, including I-495, Route 123, Route 106, and other major roadways. It includes substantial upland areas that are developed commercial and residential lands as well as undeveloped forested upland and farmland.

The Canoe River Aquifer ACEC is located adjacent to the Hockomock Swamp ACEC and within the Taunton River basin. It is generally defined by the Canoe River watershed and the underlying aquifer. It has an extensive system of surface waters, wetlands, floodplains, and high-yield aquifers. The aquifers provide high quality drinking water from wells to four of the towns located within the ACEC, Easton, Sharon, Mansfield and Norton.

The ACEC provides a rich and diverse habitat for wildlife including rare and endangered species habitat and Atlantic white cedar swamps. The upland portions of the area are a mix of open fields, deep woods, transitional woodlands, and more than 1,000 acres of productive farmland and cranberry bogs. The ACEC also includes municipal and nonprofit conservation and recreational lands, and rich archaeological and historic resources, as further detailed in Chapter 4.8, *Cultural Resources*.

Three Mile River Watershed ACEC—The Three Mile River Watershed ACEC, designated in 2008, covers approximately 14,276[20] acres in Dighton, Norton, and Taunton. The ACEC is fragmented by Route 140, a major transportation corridor, and several other major roadways. It includes substantial upland areas that are developed commercial and residential lands as well as undeveloped forested upland and farmland. The Attleboro Secondary and Whittenton Branch are in close proximity to the Three Mile River Watershed ACEC in the vicinity of Whittenton Junction (Figure 4.10-6a).

The Three Mile River Watershed is located south and adjacent to two other designated ACECs, the Canoe River Aquifer and Hockomock Swamp. The ACEC includes a wetland and stream complex tributary to the Taunton River and is located within the Taunton River Watershed. The resources of the area include fishery habitat, inland wetlands, inland surface waters, water supply areas, natural hazard areas including floodplains, agricultural areas including farmland and forestry land, archaeological and historical resources, habitat resources including state-listed rare species habitat, and special use areas including undeveloped natural areas, public recreational areas, and scenic areas.

The Three Mile River Watershed ACEC provides habitat for at least seven species listed as rare, endangered, or of special concern by the Natural Heritage and Endangered Species Program (NHESP) and contains many important habitats. Approximately 5,881 acres within the ACEC are identified as Core

[19] DCR. 2013. Canoe River Aquifer, Snake River, Watson Pond, and Lake Sabbatia. Website: http://www.mass.gov/eea/agencies/dcr/conservation/acec/canoe-river-aquifer-snake-river-watson-pond.html.
[20] DCR. 2013. Three Mile River Watershed. Website: http://www.mass.gov/eea/agencies/dcr/conservation/acec/three-mile-river-watershed.html.

Habitat Area according to the NHESP's BioMap data. The floodplain provides essential breeding habitat for many reptile and amphibian species, including several NHESP listed species, as further detailed in Chapter 4.15, *Threatened and Endangered Species*.

The surface waters of the Three Mile River are the core of the ACEC and were a former herring run. Currently, the river provides one of the best warm water fisheries in the area. The quality of the water in the river, due in part to the largely undeveloped river corridor and surrounding lands, enables the Three Mile River Watershed to provide a large area of outstanding habitat.

Protected Public Open Space

Table 4.10-2 lists the protected public open space within 0.25 mile of the Stoughton Line and the Whittenton Branch, shown in Figures 4.10-5a-e and 4.10-6a-b. Selected protected public open spaces adjacent to the Stoughton Line are briefly described, based on readily available information, in the following paragraphs.

D. Forbes Estate—Located in Stoughton, adjacent to the Stoughton Line (Figure 4.10-5a), the D. Forbes Estate is conservation land owned and managed by the Town of Stoughton Conservation Commission. The conservation land totals approximately 22 acres and has limited access. The only frontage is approximately 200 feet on Island Street.

Stoughton Memorial Conservation Land—The Town of Stoughton's Memorial Conservation Land (which includes the Bird Street Conservation Lands) is a 675-acre parcel west of the Stoughton Line (Figure 4.10-5b), extending from Plain Street to the Easton town line and west of the Bird Street Conservation Area (which is not within 0.25 mile of the corridor). The Stoughton Conservation Memorial Lands represent the largest contiguous conservation area owned by the Town of Stoughton.[21] The area includes the original 55-acre parcel owned by the Bird family from the mid-1700s through the 1870s before becoming a dairy farm owned by the Connor family.

The majority of the land is wooded, but it also contains large areas of open fields. The area supports a variety of habitats, including a former quarry, old fields, a pond, marshes, forested wetlands, and forested uplands. The 14-acre pond is used for swimming and fishing. The principal access to the property is off Bird Street. The gated entrance allows pedestrians to access a system of trails used for hiking, horseback riding, and cross-country skiing that extend throughout the area and provide additional pedestrian access from West Street and Plain Street. The Conservation Commission has developed an inventory of plant and animal species observed on the property and has published a guide to the nature trails established on the land.

The area extends to the right-of-way in two locations, with a total of approximately 1,500 feet of frontage. One location is a narrow strip where the railroad closely parallels Route 138 south of Morton Street. The second location is south of Totman Farm Road, extending to the Easton town line on the west side of the right-of-way. The majority of the area and all of the developed trail system are more than 1,000 feet from the MBTA right-of-way.

Hockomock Swamp Wildlife Management Area—A description of this area is included above in the discussion of the Hockomock Swamp ACEC.

Pine Swamp Conservation Area—Pine Swamp is a 275-acre wetland system located in western Raynham and consisting of several properties that are owned by the Town of Raynham Conservation Commission. The Stoughton Alternatives crosses the swamp in a 1-mile segment from King Phillip Street to East Britannia Street (Figure 4.10-5-d); however, the Whittenton Alternatives would avoid crossing this area as the Whittenton Branch diverges to the southwest at Raynham Junction, north of the Pine Swamp. The Pine Swamp Conservation Area consists of forested and marsh wetlands associated with Pine Swamp, an area that is located within estimated habitat of several rare wetlands species, and supports an Atlantic white cedar swamp community. The former railroad bed through the Conservation Area is owned by the Taunton Municipal Light Corporation, and maintained as a utility corridor with an overhead power line. As indicated by the Town of Raynham municipal assessor office's maps, the utility corridor right-of-way is not owned by the Town of Raynham as Conservation Land.

The Taunton Municipal Light Corporation periodically maintains the right-of-way by clearing vegetation on the right-of-way and in the adjacent wetland. Although there are no trails or designated points of public entry, the former rail right-of-way is used by pedestrians, all-terrain vehicles, off-road motorbikes, and other vehicles.

Hartshorn Park—Hartshorn Park is off Longmeadow Road and adjacent to the Stoughton Line in Taunton. The park is immediately east of the proposed Taunton (Dean Street) Station site (Figure 4.10-5e). Owned by the City of Taunton and operated by the Parks and Recreation Department, Hartshorn Park contains two baseball diamonds used for adult softball and a children's play area.

Private Open Space

Private open space within 0.25 mile of the Stoughton Line or the Whittenton Branch consists of the Sheep Pasture area described below.

Sheep Pasture—Sheep Pasture is east of the Stoughton Line and southeast of Easton Village in Easton (Figure 4.10-5b). The pasture is adjacent to the Old Baldwin Street Dump. The approximately 154-acre Sheep Pasture is owned and managed by the Natural Resources Trust of Easton and serves as the Natural Resources Trust of Easton's headquarters. Sheep Pasture is a wildlife sanctuary and the Natural Resources Trust of Easton operates many educational programs from this site, including day camps for children.

4.10.3 Analysis of Impacts and Mitigation

This section identifies the effects to protected open space or designated ACECs that may result from implementing each of the proposed South Coast Rail project alternatives (including railroad or highway alignments, train or bus stations, and layover facilities).

4.10.3.1 Impact Assessment Methodology

As required by the CEQ under NEPA, the analysis of the environmental consequences includes discussion of the direct and indirect effects of a proposed action, and their significance. Direct effects are defined as those "which are caused by the action and occur at the same time and place." Indirect

effects are defined as those "which are caused by the action and are later in time or farther removed in distance, but are still reasonably foreseeable. Indirect effects may include growth inducing effects and other effects related to induced changes in the pattern of land use, population density or growth rate, and related effects on air and water and other natural systems, including ecosystems."

Similarly, MEPA requires "a detailed description and assessment of the negative and positive potential environmental impacts of the Project and its alternatives. The EIR [Environmental Impact Report] shall assess (in quantitative terms, to the maximum extent practicable) the direct and indirect potential environmental impacts from the Project that are within the Scope. The assessment shall include both short-term and long-term impacts for all phases of the Project (e.g., acquisition, development, and operation) and cumulative impacts of the Project, any other Projects, and other work or activity in the immediate surroundings and region."

- The impact assessment focuses on acquisition of property within protected open spaces or ACECs, responding to these aspects of the Certificate requirements listed above. Other requirements, such as evaluation of wetlands, water resources, biodiversity, and rare species within protected open spaces or ACECs, are addressed in detail in other sections specific to those issues and summarized in this section.

The methods for evaluating of potential direct and indirect effects of the South Coast Rail alternatives to protected open spaces and ACECs are described below.

Method for Assessing Direct Impacts

Potential direct impacts to protected open spaces and ACECs were evaluated by reviewing areas where new construction would be required for each of the alternative alignments with respect to mapped sites to identify where the corridors passed through, were adjacent to, or were proximate to (within 0.5 mile of) these sites. For the purposes of this evaluation, "new construction" is defined as upgrading existing rail lines, reconstructing rail lines along historic railroad alignments, replacing existing railroad bridges and culverts, constructing new permanent or temporary railroad bridges, reconfiguring at-grade road/railroad crossings, and constructing new grade-separated road/railroad crossings.

The analysis was conducted to determine if:

- Land acquisition would be required; or
- The temporary or permanent use of protected open space or ACECs would adversely affect traffic patterns near or access to or within those protected open spaces or ACECs.

For the purposes of this evaluation, "land acquisition" is defined as taking a greater than 500-square-foot portion, or a sliver great than 10 feet wide, of any parcel outside of the existing rights-of-way to accommodate permanent construction impacts, and are based upon conceptual engineering plans. Parcel acquisition below this threshold was excluded because using small portions of the protected open space or ACEC is unlikely to change the conservation or recreation function of the parcel. Final engineering for the selected alternative would allow more specific identification of land acquisition requirements of small portions of parcels. Minor open spaces, such as landscaping elements along public roadways, were also not considered in the evaluation of land acquisition. Temporary construction impacts outside of the existing rights-of-way would not require land acquisition and are therefore not considered in this evaluation. However, obtaining a temporary construction easement in an Article 97

land could require approval by the legislature. Land acquisition within ACECs was only reviewed with respect to publicly owned parcels.

Aerial photographs were examined in reference to preliminary engineering plans to identify encroachments into protected open spaces or ACECs, and to identify potential substantive changes access to the sites based upon any necessary road closures or realignments. Final engineering plans may show an increase or decrease of the actual area of acquisition required.

The most current version of the South Coast Rail design was reviewed to identify where open space impacts may occur. Potentially impacted locations were evaluated to determine acquisition requirements and ascertain the nature and extent of certain open space resources, such as visual and recreational values (e.g., Wild and Scenic River designation), at each location.

Specific resource aspects of protected open spaces or ACECs are addressed in other chapters, as follows:

- Chapter 4.14, *Biodiversity, Wildlife, and Vegetation*, includes an assessment of the alternatives' impact to biodiversity in protected open spaces or ACECs.
- Chapter 4.11, *Farmland Soils*, includes a review of agricultural development to identify locations where activities associated with each alternative could adversely impact prime farmland, unique farmland, or farmland of statewide or local importance, within protected open spaces or ACECs.
- Chapter 4.8, *Cultural Resources*, includes a review of cultural resources data to identify locations where alternatives could adversely impact historic or archaeological resources in protected open spaces or ACECs.
- Chapter 4.15, *Threatened and Endangered Species*, includes a review of biological data to identify locations where alternatives could adversely impact rare species in protected open spaces or ACECs.
- Chapter 4.17, *Water Resources*, includes a review of hydrologic data to identify locations where alternatives could adversely impact water quality or hydrology in protected open spaces or ACECs.
- Chapter 4.16, *Wetlands*, identifies wetlands where alternatives could adversely impact the functions and values of these resources in protected open spaces or ACECs.

Method for Assessing Indirect Impacts

Potential indirect effects to protected open spaces and ACECs are addressed in Chapter 5, *Summary of Indirect Effects and Cumulative Impacts.* The analysis of indirect effects was conducted to identify any growth-inducing effects and other effects related to induced changes that may result in a change in use of protected open spaces or ACECs.

4.10.3.2 Impacts of Alternatives by Element

No-Build (Enhanced Bus) Alternative

The No-Build Alternative (Enhanced Bus) would improve transit service to Boston from New Bedford, Fall River, and Taunton by adding more buses but using smaller capital investments than are proposed in the Build Alternatives. Under this alternative, no new rail or bus service would be provided to Southeastern Massachusetts.

The No-Build Alternative plan includes bus schedule enhancements, transportation demand management, and transportation policy enhancements for commuter bus. In addition to these enhancements, and incentives would enable the private commuter bus service operators to acquire a new fleet of fuel efficient and clean emission buses. Ideally, these buses would provide rider comfort and amenities comparable to commuter rail service.

Existing commuter bus service to Boston from New Bedford, Fall River, and Taunton is currently provided by three commuter bus carriers: DATTCO provides Boston – New Bedford service; Peter Pan provides Boston – Fall River bus service; and Bloom provides Boston – Taunton service.

Some of these alignments and associated Park and Ride facilities pass through or are in proximity to protected open spaces and/or ACECs. However, given that these alignments would not change and no new construction or land acquisition would be required for the No-Build Alternative, this alternative would not directly affect protected open spaces and/or ACECs. Should three of the Park-and-Ride facilities that are at capacity need to be expanded or relocated, such could be achieved without requiring construction within protected open spaces and/or ACECs.

Southern Triangle (Common to All Build Alternatives)

Portions of the rail lines within the southern part of the South Coast Rail study area are common to all Build Alternatives. These rail lines form a rough triangular shape running south from Myricks Junction to Fall River (the Fall River Secondary) and from Weir Junction through Myricks Junction to New Bedford (the New Bedford Main Line), and are therefore referred to as the Southern Triangle (Figure 1.4-1). The following sections describe the environmental consequences to protected open spaces and ACECs that may result from new construction for these two components of the Build Alternatives. The northern part of the South Coast Rail study area is described in subsequent sections.

Fall River Secondary Rail Segment

The 12.3 miles of existing freight track along the existing Fall River Secondary freighttrack would be upgraded and maintained to Federal Rail Administration (FRA) Class 7 options[22] for the South Coast Rail project. The line would be double-track from Weir Junction to Myricks Junction, with a 0.9-mile third track for freight movements near Taunton Depot Station. A short segment of the line would be double-track south of Myricks Junction, 0.8 mile. The remainder of the line would be single-track, with the exception of a 1.8-mile double-track section in Freetown and a 1.7-mile section in New Bedford. Public at-grade road/railroad crossings that would remain open would be reconfigured and/or improved to meet current safety standards. The existing freight service using the Fall River Secondary is diesel-powered; no electrical infrastructure is present. New catenary supports and wires would need to be

[22] FRA. 2009. 49 CFR 213.9 Classes of Track: Operating Speed Limits. US Department of Transportation, Federal Rail Administration.

constructed along the length of the line, and traction power facilities at selected locations, for the electric alternatives.

Two new stations would be constructed in Fall River (Battleship Cove and Fall River Depot) and one new station would be constructed in Freetown (Freetown). One new layover facility would be constructed in Fall River, at the Weaver's Cove East site. Potential impacts to protected open spaces and ACECs resulting from constructing and using the new stations and layover facility along the Fall River Secondary are considered in Sections 4.10.3.3 and 4.10.3.4, respectively.

Several protected open spaces are adjacent to the Fall River Secondary. No ACECs are present along this corridor and, accordingly, no direct effects to ACECs would result from the Fall River Secondary construction activities. Although protected open spaces are near the Fall River Secondary, no protected open space land would be acquired for improving the line for either the electric or the diesel alternatives. Figure 4.10-4a-c shows the Fall River Secondary alignment construction disturbance limits and the nearby protected open spaces.

Access to protected open spaces along the Fall River Secondary would not be affected by the Build Alternatives.

New Bedford Main Line Rail Segment

The 19.4-mile existing freight tack along the New Bedford Main Line would be upgraded to FRA Class 7 options for the South Coast Rail project. The line would be double-track from Weir Junction to Myricks Junction, with a 0.9-mile third track for freight movements near Taunton Depot Station. A short segment of the line would be double-track south of Myricks Junction, 0.8 mile. The remainder of the line would be single-track, with the exception of 1.8-mile double-track section in Freetown and a 1.7-mile section in New Bedford. Public at-grade road/railroad crossings that would remain open would be reconfigured and/or improved to meet current safety standards. The existing freight service using the New Bedford Main Line is diesel-powered; no electrical infrastructure is present. New catenary supports and wires would need to be constructed along the length of the line, and traction power facilities at selected locations, for the electric alternatives. Two new train stations would be constructed in New Bedford (King's Highway and Whale's Tooth) and one new train station would be constructed in Taunton (Taunton Depot). One new layover facility would be constructed in New Bedford at either the Wamsutta site. Potential impacts to protected open spaces and ACECs resulting from constructing and using the new stations and layover facility along the New Bedford Main Line are considered in Sections 4.10.3.3 and 4.10.3.4, respectively.

The New Bedford Main Line passes through or is adjacent to several protected open spaces (Figures 4.10-3a-d). No ACECs are present along this corridor and, accordingly, no direct effects to ACECs would result from the New Bedford Main Line construction activities.

No protected open space would be acquired for improving the New Bedford Main Line, and public access to nearby protected open spaces would not be impacted.

Stoughton Electric Alternative

The Stoughton Electric Alternative north of the Southern Triangle would comprise two segments: a portion of the Northeast Corridor and all of the Stoughton Line. This alternative would use the Northeast Corridor from South Station to Canton Junction. From Canton Junction, the existing Stoughton Line

would be used to the existing Stoughton Station. Commuter rail service would be extended, reconstructing a railroad on an out-of-service railroad bed, south through Raynham Junction to Weir Junction in Taunton. This alignment joins the New Bedford Main Line at Weir Junction, the northern end of the Southern Triangle.

This evaluation focuses on the existing and extended Stoughton Line segment. No construction would be required in the Northeast Corridor segment for this alternative, and the Southern Triangle portions were addressed above.

The existing single track commuter rail line would be upgraded and maintained to FRA Class 7. A new second track would be constructed from Canton Junction to the existing Stoughton Station, a distance of 3.8 miles, where existing passenger service ends. A new double track would extend south of Stoughton Station to the proposed North Easton Station. The remainder of the line south to Weir Junction would be single- track, with a 2.2-mile long double-track section in Raynham, and a 0.6 mile long double-track section in Taunton. Approaching Weir Junction, an additional 0.4 mile siding track would be provided for freight use only. All of the existing at-grade road/railroad crossings would be reconfigured and/or improved to meet current safety standards. New catenary supports and wires would be constructed along the length of the line, and electric substations at selected locations.

One existing train station along the Stoughton Line would be reconstructed (Canton Center). Four new train stations would be constructed along this alignment (Stoughton, North Easton, Easton Village, Raynham Park, and Taunton). No new layover facilities would be constructed along this segment. Potential impacts to protected open spaces and ACECs from reconstructing the existing and developing the new stations along the Stoughton Line are considered in Section 4.10.3.3.

One ACEC is present along this corridor, the Hockomock Swamp ACEC. The Stoughton Line passes through the Hockomock Swamp ACEC beginning at Depot Street in Easton and extending south to near I-495 in Raynham. A 1.6-mile long trestle would be constructed where the Stoughton Line passes through the Hockomock Swamp within the ACEC. The Stoughton Line also passes through or is adjacent to numerous protected open spaces, including Pine Swamp south of Taunton.

The estimated area of protected open space and publicly owned parcels in the ACEC required for constructing the Stoughton Electric Alternative north of the Southern Triangle is listed in Table 4.10-3 and shown in Figures 4.10-5a-e. As a result of the ongoing refinement of the design since publication of the DEIS/DEIR, and in particular the track alignment, acquisition requirements of Article 97-protected properties have been reduced by avoiding or minimizing encroachments into these properties. For example the DEIS/DEIR estimated that the Stoughton Electric Alternative would impact 0.29 acre of Easton Conservation Land, an Article 97-protected property. However, the current design of the Stoughton Electric Alternative no longer requires that land acquisition. Based on the current level of design, this alternative would require the acquisition of a small portion of one parcel of Article 97-protected property.

The required acquisition in Stoughton, a 0.16-acre portion of the 19.38-acre Stoughton Memorial Conservation Land, would be used to re-route Morton Street (Figure 4.10-7). This acquisition of Article 97-protected land would be necessary in order to accommodate the western edge of the new road and an embankment sloping down from the road bed to the adjacent natural ground surface. The Easton acquisition would be used for a traction power facility (TPSS-1).

Table 4.10-3 Stoughton Electric Alternative Protected Open Space Acquisition

City/Town	Name	Ownership	Use	Acquisition Area (acres)
Stoughton	Stoughton Memorial Conservation Land	Public	Conservation/Recreation	0.16
Easton	Southeast Regional Vocational Tech School	Public	Recreation	0.50
Total				0.66

Sources: MassGIS 2002, 2005; municipal data 2009, aerial mapping and online research (various).

No land would be acquired from the Hockomock Swamp WMA or the Pine Swamp protected open space. The existing railroad grade is already owned by MBTA and is therefore not Article 97 land.

The existing right-of-way through the Hockomock Swamp is typically 66 feet wide, and all work for the trestle would be accomplished within the right-of-way. No land acquisition from the Massachusetts Division of Fisheries and Wildlife would be required within the Hockomock Swamp WMA. Access for constructing the trestle would be from the north at Foundry Street and from the south at Racetrack Crossing. There would be no requirement for a separate access road, either within or outside the right-of-way. Access for operations and maintenance would be from the trestle structure. A track turnout is proposed on the superstructure for maintenance vehicles. Areas below the superstructure would be accessed from each of the piers with a ladder. There would be no need for vehicular access at ground level.

Impacts to the Hockomock Swamp open space would include the loss of public access to the swamp along the railroad alignment, and a 0.5 acre property acquisition for the construction of a traction power facility (TPSS-1) within the Hockomock Swamp ACEC, located at the Southeast Regional Vocational Tech School in Easton.

No street closures in the immediate vicinity of protected open spaces or the ACEC are planned for the Stoughton Electric Alternative. During operations, temporary delays in traffic flow may occur at any road/railroad at-grade crossings; none of these delays are considered likely to substantively impact access to protected open spaces or the ACEC. Access to the Hockomock Swamp ACEC and WMA would be impacted along the Stoughton Line railroad bed: informal recreational usage of the railroad bed by pedestrians, bicyclists, all-terrain vehicles, and other similar users would be terminated. Those users would be forced to seek other sites or abandon these activities. It is not known if relocated recreational activities would be likely to occur elsewhere within the Hockomock Swamp or at other sites that are not either protected open spaces or ACECs.

Stoughton Diesel Alternative

The Stoughton Diesel Alternative is identical to the Stoughton Electric Alternative with the exception of the locomotive power source. Diesel-powered train service differs from electric-powered service in not requiring electrical infrastructure. There would be no overhead catenary system or traction power facilities for the Stoughton Diesel Alternative. All other aspects of the Stoughton Diesel Alternative are common with the Stoughton Electric Alternative, as described above.

The estimated area of protected open space required for constructing the Stoughton Diesel Alternative in Stoughton Line segment is listed in Table 4.10-4 and shown in Figure 4.10-7. This land acquisition is necessary for the rerouting of Morton Street. This parcel is owned by the Town of Stoughton, and would therefore be considered Article 97 land subject to the provisions of the EEA's Article 97 Land Disposition Policy.

Table 4.10-4 Stoughton Diesel Alternative Protected Open Space Acquisition

City/Town	Name	Ownership	Use	Acquisition Area (acres)
Stoughton	Stoughton Memorial Conservation Land	Public	Conservation/Recreation	0.16

Sources: MassGIS 2002, 2005; municipal data 2009, aerial mapping and online research (various).

Whittenton Electric Alternative

The Whittenton Electric Alternative is identical to the Stoughton Electric Alternative alignment described above except for the segment of the Stoughton Line between Raynham and Weir Junctions. Specifically, at Raynham Junction the Whittenton Alternative would divert to the southwest to connect to the abandoned Whittenton Branch. The Whittenton Branch would extend south and west to the Attleboro Secondary at Whittenton Junction. Along the Attleboro Secondary, the Whittenton Electric Alternative would extend to Weir Junction in Taunton. Track infrastructure improvements would include 3.6 miles of new single-track on the Whittenton Branch and 2.2 miles of single-track reconstruction on the Attleboro Secondary with a 0.3-mile siding reserved for the proposed Dana Street Station. The southernmost portion of the Stoughton Line, from Raynham Junction to Weir Junction (a distance of 5.1 miles), would not be used if this alternative is selected.

This evaluation focuses on the Whittenton Branch and Attleboro Secondary components; other portions of this alternative are described in in the preceding Southern Triangle and Stoughton Electric Alternative sections.

New track would be placed on the out-of-service Whittenton Branch railroad bed from Raynham Junction to Whittenton Junction, and 2.5 miles of the Attleboro Secondary track infrastructure would be reconstructed. Existing public at-grade road/railroad crossing would be reconfigured and/or improved to current safety standards. New catenary supports and wires would be constructed along the length of the line. One new station (Dana Street) would be constructed along the Attleboro Secondary.

The Whittenton Branch and Attleboro Secondary do not pass through nor are they adjacent to any ACEC. Although these portions of the Whittenton Electric Alternative are near the Canoe River Aquifer ACEC, the Three Mile River ACEC and the southern limit of the Hockomock Swamp ACEC, no ACECs or protected open space would be acquired. Additionally, the Whittenton Electric Alternative would not use the southernmost portion of the Stoughton Line, and would therefore not pass through the Pine Swamp protected open space, south of Raynham.

Refinements to the track design of the Whittenton Electric Alternative have eliminated the protected open space acquisition described in Section 4.10.3.2 of the DEIS/DEIR. No protected open space, including land protected by Article 97, would be acquired for the Whittenton Branch or Attleboro Secondary. Thus the Whittenton Electric Alternative would have the same impacts on protected open space and ACECs as the Stoughton Electric Alternative (see Table 4.10-3 above).

No public street closures in the vicinity of the protected open space or the Hockomock Swamp ACEC are planned. During operations, temporary delays in traffic flow may occur at the road/railroad at-grade crossings; none of these delays are considered likely to permanently impact access to the protected open space or the ACEC.

Whittenton Diesel Alternative

The Whittenton Diesel Alternative is identical to the Whittenton Electric Alternative with the exception of the locomotive power source. As described above for the Stoughton Diesel Alternative, diesel-powered train service differs from electric-powered service in not requiring electrical infrastructure. The footprint of the affected area would be smaller since power traction facilities would not be necessary. The Whittenton Diesel Alternative would not require the acquisition of any protected open space, including land protected by Article 97, along the Whittenton Branch or Attleboro Secondary portions of the alignment. As such, the Whittenton Diesel Alternative would have the same impacts on protected open space and ACECs as the Stoughton Diesel Alternative (see Table 4.10-4above).

4.10.3.3 Stations

This section provides basic descriptions of each train station, an indication of its location in or near any protected open space or ACEC, and a qualitative evaluation of the direct and indirect impacts to these sites potentially resulting from constructing (or reconstructing) and using each station for the South Coast Rail project. Because stations have different types of impacts and settings and are in several cases shared among multiple alternatives they were addressed separate from the alignments, in order to avoid redundant discussion.

Battleship Cove Station

The Battleship Cove Station (Figure 4.10-8) would be a new station constructed along the Fall River Secondary that would serve all Build Alternatives. It would be located on Water Street in Fall River, near the southern terminus of the Fall River Secondary. The Battleship Cove Station would not include any parking facilities; it is intended as a drop-off/pick-up station.

The Battleship Cove Station site is immediately adjacent to land previously developed by the city for the Ponta Delgada Plaza, a protected open space. The site is also near three other protected open spaces: Fall River Heritage State Park, Heritage Park, and Turner Playground. This site is not within or near any ACECs. No protected open space acquisition would be required for constructing the Battleship Cove Station. An agreement with the City of Fall River would be negotiated to use the Ponta Delgada Plaza as a drop-off/pick-up point for passengers using the train station.

Increased automobile traffic at the Ponta Delgada Plaza may result from using the new Battleship Cove Station there, as the commuters may use cars to transport themselves to and from the drop-off/pick-up station. Water Street also provides access to the Fall River Heritage State Park; access to this protected open space may also be impacted by increased traffic congestion at the Battleship Cove Station. However, the level of service on the adjacent streets would not change, and peak traffic usage (morning and evening commute times) would not coincide with likely park recreational use (mid-day).

Canton Center Station

The Canton Center Station (Figure 4.10-9) is an existing train station along the Stoughton Line that would be reconstructed and would serve all Build Alternatives. Located at 710 Washington Street in Canton, this station is an active transit facility that is near the Curtis Road Conservation Area and Bolivar Swimming Area protected open spaces. This site is not within or near any ACECs.

The Canton Center Station is located on Washington Street, which also provides local access to the nearby Curtis Road Conservation Area. The Bolivar Swimming Area is accessible from Bolivar Street,

which intersects Washington Street. Given the current active use of the Canton Center Station as a transit facility and the distance to these protected open spaces, substantive changes in access to the Curtis Road Conservation Area or the Bolivar Swimming Area are unlikely to occur as a result of further developing the Canton Center Station.

Dana Street Station

The Dana Street Station (Figure 4.10-10) would be a new station constructed along the Attleboro Secondary that would serve the Whittenton Alternative only. The proposed Dana Street Station site is located just south of the Danforth Street grade crossing, on the east side of the railroad between the alignment and Dana Street.

The Dana Street Station site is a currently vacant lot that is not near any protected open spaces or ACECs. No protected open space land would be acquired for constructing the Dana Street Station.

Easton Village Station

The Easton Village Station (Figure 4.10-11) would be a new train station constructed along the Stoughton Line that would serve all Build Alternatives. The Easton Village Station site is on Sullivan Avenue at the transition point to Mechanic Street (near the intersection with Pond Street) in Easton.

The Easton Village Station site is a partially developed parcel that is adjacent to the Veterans Memorial Park, Frothingham Park, and Ricker Field protected open spaces. It is not within or near any ACECs. No protected open space land would be acquired for constructing the Easton Village Station.

The Easton Village Station site is on Sullivan Street, across the road from Veterans Memorial Park. Local traffic likely uses Sullivan Street to access the park. Temporary delays due to traffic congestion resulting from commuters accessing the Easton Village Station may impact traffic patterns and access to this proximate protected open space. However, peak traffic usage (morning and evening commute times) would not coincide with likely park recreational use (mid-day). Frothingham Park is accessed from Barrows Street or Sheridan Street, neither of which would be directly impacted by the Easton Village Station. Ricker Field is accessed from Main Street, a surface street separated from Sullivan Street by the Stoughton Line. Access to Ricker Field is unlikely to be impacted by use of the Easton Village Station.

Fall River Depot Station

The Fall River Depot Station (Figure 4.10-12) would be a new station constructed along the Fall River Secondary to serve all Build Alternatives. It would be located near the intersection of North Davol Street and Pearce Street in Fall River.

The Fall River Depot Station site is a previously developed parcel that is near five protected open spaces. This site is not within or proximate to any ACECs. No protected open space land would be acquired for constructing the Fall River Depot Station.

Local traffic is unlikely to use the surface streets in the immediate vicinity of the Fall River Depot Station site to access the nearby protected open spaces, all of which are separated from the site by major highways (Routes 138 and 79) or the existing Fall River Secondary, and have better access from other streets. No changes in access to the protected open spaces are expected.

Freetown Station

The Freetown Station (Figure 4.10-13) would be a new station constructed along the Fall River Secondary to serve all Build Alternatives. It would be located along South Main Street in Freetown.

The Freetown Station site is a previously developed parcel that is near the Freetown-Fall River State Forest protected open space. It is not proximate to or within any ACECs. No protected open space land would be acquired for constructing the Freetown Station.

The portion of the Freetown-Fall River State Forest proximate to the Freetown Station site is an isolated parcel, separated from the main body of the state forest by Route 24 and the existing Fall River Secondary. The isolated parcel is also separated from the Freetown Station site by the Fall River Secondary. Access to this isolated parcel is unlikely to be affected by constructing or using the Freetown Station.

King's Highway Station

The King's Highway Station (Figure 4.10-14) would be a new station constructed along the New Bedford Main Line to serve all Build Alternatives. It would be located near the intersection of King's Highway and Tarkiln Hill Road in New Bedford. The intersection would be reconfigured as part of the South Coast Rail project.

The King's Highway Station site is a previously developed parcel that is near two protected open spaces: the Charles S. Ashley School and Brooklawn Park. This location is not within or near any ACEC. No protected open space land would be acquired for constructing the King's Highway Station.

The nearby protected open spaces are a school and a neighborhood park, both with several surface street access options. Commuter automobile traffic to and from the King's Highway Station would be using different routes and generally moving away from, rather than toward, these protected open spaces. And, peak traffic usage (morning and evening commute times) would not coincide with likely park recreational use (mid-day). Access to the protected open spaces would not be impacted by the reconfigured intersection or the King's Highway Station.

North Easton Station

The North Easton Station (Figure 4.10-15) would be a new train station constructed along the Stoughton Line that would serve all Build Alternatives. It would be located at 21 Washington Street in Stoughton, behind the Roche Brothers Shopping Plaza.

The North Easton Station site is an undeveloped parcel that is near Town of Easton Conservation Land, Wedgewood Drive Area, and Stoughton Memorial Conservation Land protected open spaces. It is not within or near any ACECs. No protected open space land would be acquired for constructing the North Easton Station.

Local traffic likely uses Washington Street (Route 138) to access the nearby Easton Conservation Land and the Stoughton Memorial Conservation Land. Temporary delays due to congestion resulting from commuters accessing the North Easton Station may impact access to these nearby protected open spaces. Access to the Wedgewood Drive Area is from alternate routes distant from the station site.

Raynham Park Station

The Raynham Park Station (Figure 4.10-16) would be a new train station constructed along the Stoughton Line that would serve the Build Alternatives. It would be located at 1958 Broadway in Raynham, at the former Raynham Park greyhound dog racing facility.

The Raynham Park site is a developed parcel that is near the Hockomock Swamp WMA-protected open space and partially within the Hockomock Swamp ACEC. No protected open space or publicly owned parcels in the ACEC would be acquired for constructing the Raynham Park Station.

Commuters accessing the Raynham Park Station would use Broadway (Route 138), passing through the former Raynham Park greyhound dog racing facility property. Broadway also provides access to the Hockomock Swamp WMA and ACEC at numerous points distant from the Raynham Park Station site. Temporary delays due to traffic congestion on Broadway may result during peak usage periods, but are unlikely to impact access to the protected open space or ACEC.

Stoughton Station

The relocated Stoughton Station (Figure 4.10-17) would be a new train station that would serve all Build Alternatives. The station would be constructed along the Stoughton Line, west of the existing railroad tracks and north of Brock Street. The site is a previously developed area consisting of commercial/industrial businesses, parking areas, and some undeveloped wooded land.

The Stoughton Station site is privately owned and does not include public open space. The site is proximate to five protected open spaces but is not within or proximate to any ACECs. No protected open space land would be acquired for reconstructing the Stoughton Station.

Local traffic likely uses Park Street, Washington Street, and Cushing Street to access the nearby protected open spaces (Marks Field, Woods Pond, Meads Meadow, Halbran Field, and Lehan Field). These streets are located in the vicinity of the Stoughton Station. Use of these streets by commuters during morning and evening commute times would not coincide with the use of these streets to access to nearby protected open spaces during the mid-day. Given the current, active use of the Stoughton Station for commuter rail service, no additional direct impact to access to nearby protected open spaces from implementing the South Coast Rail project is likely.

Taunton Station

The Taunton Station (Figure 4.10-18) would be a new train station constructed along the Stoughton Line that would serve the Stoughton Alternatives. It would be located near the intersection of East Arlington Street and William Hooke Lane in Taunton.

The Taunton Station site is a previously developed parcel near the Hartshorn Park and Plonka Property protected open spaces. It is not within or proximate to any ACECs. No protected open space land would be acquired for constructing the Taunton Station.

Commuters would likely access the Taunton Station by Arlington Street or Dean Street (Route 44). Temporary delays due to congestion during peak usage periods may result on these roads. Both Hartshorn Park and the Plonka Property are accessed from Longmeadow Road, which intersects Dean Street east of the proposed station location. Traffic congestion near the site is unlikely to extend as far as the intersection with Longmeadow Drive. Additionally, peak traffic usage (morning and evening

commute times) would not coincide with likely park recreational use (mid-day). Traffic patterns near and access to these protected open spaces would not be impacted by use of the Taunton Station.

Taunton Depot Station

The Taunton Depot Station (Figure 4.10-19) would be a new station constructed along the New Bedford Main Line that would serve all Build Alternatives. It would be located at 872 County Street in Taunton, behind the existing Target Plaza.

The Taunton Depot Station site is an undeveloped parcel that is not within or near any protected open spaces or ACECs.

Whale's Tooth Station

The Whale's Tooth Station (Figure 4.10-20) would be a new station constructed along the New Bedford Main Line constructed to serve all Build Alternatives. It would be located near the intersection of Acushnet Avenue and Hillman Street, near the southern terminus of the New Bedford Main line. The City of New Bedford has constructed a parking lot at this site in anticipation of the future station.

The Whale's Tooth Station site is a previously developed parcel that is near the New Bedford Whaling National Historic Park, Fisherman's Wharf Pier #3, State Pier, Clasky/Common Park, and the John Avery Parker School protected open spaces. Several un-named protected open spaces are also proximate to this site. No ACECs are near the Whale's Tooth Station site. No protected open space land would be acquired for constructing the Whale's Tooth Station.

Local traffic may use Acushnet Avenue, Hillman Street, or the nearby Herman Melville Boulevard to access the New Bedford Whaling National Historic Park and the adjoining Fisherman's Wharf Pier #3 or State Pier. Commuter traffic to and from the Whale's Tooth Station may temporarily increase congestion on these roads during high usage periods, causing temporary delays in accessing these protected open spaces. However, peak traffic periods (morning and evening commute times) are unlikely to coincide with use of these protected open spaces (mid-day). No changes in access to the other proximate protected open spaces are expected.

4.10.3.4 Layover Facilities

The Build Alternatives would require midday storage in the Boston area. The mid-day train layover facility is being investigated separately as part of the South Station Expansion Project. Two overnight layover facilities are planned for the Southern Triangle: one each at or near the end of the Fall River Secondary and the New Bedford Main Line. Of the three alternative sites identified in Fall River, the Weaver's Cover East site has been selected as the preferred layover facility site. Of the two alternative sites in New Bedford, the Wamsutta site been identified as the preferred site. This section provides descriptions of each layover facility, an indication of its location in or near any protected open space or ACEC and any parcel acquisition requirements, and a qualitative evaluation of the direct and indirect impacts to these sites potentially resulting from constructing and using these facilities for the South Coast Rail project.

Wamsutta Layover Facility

The Wamsutta site layover facility (Figure 4.10-21) would be constructed along the New Bedford Main Line and would serve all Build Alternatives. It would be located near the intersection of Wamsutta Street and Herman Melville Boulevard, near the southern terminus of the New Bedford Main line.

The Wamsutta layover facility alternative location is a previously developed site that is near the Clasky/Common Park and John Avery Parker School. This site is not within or near any ACECs. No protected open space land would be acquired for constructing a layover facility at the Wamsutta site.

Traffic on Hermann Melville Boulevard would pass by the Wamsutta site, but access to the nearby protected open spaces is afforded by other surface streets which are separated from the Wamsutta site by Route 18. No changes in access to the other protected open spaces are expected.

Weaver's Cove East Layover Facility

The Weaver's Cove East site layover facility (Figure 4.10-22) would be constructed along the Fall River Secondary and would serve all Build Alternatives. It would be located in Fall River off of Main Street between the existing Fall River Secondary freight line and Main Street, approximately 2.5 miles from the southern terminus of the Fall River Secondary.

The Weaver's Cove East site is a partially developed parcel that is not located within or near any protected open space or ACECs.

4.10.3.5 Summary of Impacts by Alternative

This section summarizes the direct effects to protected open spaces and ACECs potentially resulting from implementing each of the South Coast Rail project alternatives. The individual components of each element are grouped by alternative, and the potential direct impacts to protected open spaces and ACECs are tabulated.

Stoughton Electric Alternative

The Stoughton Electric Alternative (Figure 1.4-2) would comprise the elements listed in Table 4.10-5, which also summarizes the direct effects to protected open spaces and ACECs potentially resulting from implementing this alternative.

For the Stoughton Electric Alternative, approximately 0.66 acre of land would be acquired from protected open spaces. Legal access to protected open spaces and ACECs would not be significantly impacted by constructing, reconstructing, or using the railroad alignments, stations, or layover facilities. Unauthorized access to protected open space and ACECs along the out-of-service portion of the Stoughton Line would cease.

Table 4.10-5 Summary of Potential Direct Effects to Protected Open Spaces and ACECs from the Stoughton Electric Alternative

Element/Component	Direct Effects: Acquisition Area (acres)	Direct Effects: Number of Parcels
Railroad Alignments		
Northeast Corridor	0	
Stoughton Line	0.66	2
Fall River Secondary	0	
New Bedford Main Line	0	
Stations		
Canton Center	0	
Stoughton	0	
North Easton	0	
Easton Village	0	
Raynham Park	0	
Taunton	0	
Taunton Depot	0	
Freetown	0	
Fall River Depot	0	
Battleship Cove	0	
King's Highway	0	
Whale's Tooth	0	
Layover Facility Alternatives		
Wamsutta Site	0	
Weaver's Cove East Site	0	
TOTAL	**0.66**	**2**

The Stoughton Electric Alternative's impacts to ACEC key functions and values are summarized below:

- **Biodiversity**: The Stoughton Electric Alternative is expected to affect biodiversity in the Hockomock Swamp ACEC areas adjacent to the reconstructed track to a limited degree as a result of increased train traffic that would reduce habitat quality for some wildlife species and would create a partial barrier to wildlife movement. Although partially mitigated by the Hockomock Swamp Trestle, using this railroad bed would affect the connectivity of adjacent habitats and their overall biodiversity value, as described in Chapter 4.14.

- **Farmland soils**: The Stoughton Electric Alternative would impact designated farmland soils that occur at traction power station TPSS-1, located within the Hockomock Swamp ACEC. Construction of this site would impact 1.1 acres of designated farmland soils.

- **Historic and archaeological resources**: The Stoughton Electric Alternative would not affect historic/archaeological properties known to be listed or eligible for listing in the National Register of Historic Places within any ACEC. As a result of installing the overhead catenary system, this alternative would require construction in areas of moderate sensitivity for archaeological resources. This alternative would also require construction (installing pilings for the trestle) in areas of moderate sensitivity for archaeological resources. Additional investigation would be required to determine if any archaeological resources within the Hockomock Swamp ACEC would be affected.

- **Rare species**: The Stoughton Electric Alternative would potentially impact rare species habitat within the Hockomock Swamp ACEC and Pine Swamp, as it crosses two Priority and

Estimated Habitat polygons (PH1392/EH59 and PH1297/EH1077, respectively). This alternative would result in the loss of potential habitat to species known to be present within the Priority Habitats crossed by this segment, including the eastern box turtle (*Terrepene carolina carolina*), Blanding's turtle (*Emydoidea blandingii*), blue spotted salamander (*Ambystoma laterale*), gypsywort (*Lycopus rubellus*), and Hessel's hairstreak (*Callophrys hesseli*). The Hockomock Swamp ACEC provides habitat for at least 13 species listed as rare, endangered, or of special concern by the NHESP. Within the part of the ACEC crossed by the Stoughton Alternative, four state listed species (blue-spotted salamander, Blanding's turtle, eastern box turtle, and gypsywort) are known to be present.

- **Water resources**: The Stoughton Electric Alternative would not create a new or additional discharge to the Neponset River and Sprague Pond where the Northeast Corridor passes through the Fowl Meadow and Ponkapoag Bog ACEC. The Hockomock Swamp and Fowl Meadow ACECs would also potentially be impacted from stormwater discharges to Black Brook and the East Branch of the Neponset River, respectively, from the Stoughton Electric Alternative. However, minimal impacts to ACECs from stormwater discharges would result from the project and surface or groundwater resources within the ACECs would not be impaired.

- **Wetlands**: Potential permanent wetland and waterway impacts along the Stoughton Line include the loss of 1.7 acres within the Hockomock Swamp ACEC, out of a total of 8,260 acres of wetlands within this ACEC.

Stoughton Diesel Alternative

The Stoughton Diesel Alternative would comprise the same elements as Stoughton Electric Alternative listed above (shown in Figure 1.4-2) but would not need electrical infrastructure. Table 4.10-6 summarizes the direct effects to protected open spaces and ACECs potentially resulting from implementing this alternative.

For the Stoughton Diesel Alternative, approximately 0.16 acre of land would be acquired from protected open spaces. No publicly owned parcels of ACEC land would be acquired. Access to protected open spaces and ACECs would not be significantly impacted by constructing, reconstructing, or using the railroad alignments, stations, or layover facilities.

The Stoughton Diesel Alternative's impacts to ACEC key functions and values are summarized below:

- **Biodiversity**: The Stoughton Diesel Alternative is expected to affect biodiversity in the Hockomock Swamp ACEC areas adjacent to the reconstructed track to a limited degree as a result of increased train traffic which would reduce habitat quality for some wildlife species and would create a partial barrier to wildlife movement. Although partially mitigated by the Hockomock Swamp Trestle, using this railroad bed would affect the connectivity of adjacent habitats and their overall biodiversity value, as described in Chapter 4.14.

- **Farmland soils**: The Stoughton Diesel Alternative would not impact any mapped areas of designated farmland soils within an ACEC.

Table 4.10-6 Summary of Potential Direct Effects to Protected Open Spaces and ACECs from the Stoughton Diesel Alternative

Element/Component	Direct Effects: Acquisition Area (acres)	Direct Effects: Number of Parcels

TOTAL	**0.16**	**1**

- **Historic and archaeological resources**: The Stoughton Diesel Alternative would not affect known archaeological resources within any ACEC. This alternative would require construction (installing pilings for the trestle) in areas of moderate sensitivity for archaeological resources. Additional investigation would be required to determine if any archaeological resources within the Hockomock Swamp ACEC would be affected.

- **Rare species**: The Stoughton Diesel Alternative would potentially impact rare species habitat within the Hockomock Swamp ACEC and Pine Swamp, as it crosses two Priority and Estimated Habitat polygons (PH1392/EH59 and PH1297/EH1077, respectively). This alternative would result in the loss of potential habitat to species known to be present within the Priority Habitats crossed by this segment, including the eastern box turtle (*Terrepene carolina carolina*), Blanding’s turtle (*Emydoidea blandingii*), blue spotted salamander (*Ambystoma laterale*), gypsywort (*Lycopus rubellus*), and Hessel’s hairstreak (*Callophrys hesseli*). The Hockomock Swamp ACEC provides habitat for at least 13 species listed as rare, endangered, or of special concern by the NHESP. Within the part of the ACEC crossed by the Stoughton Alternative, four state listed species (blue-spotted salamander, Blanding’s turtle, eastern box turtle, and gypsywort) are known to be present.

- **Water resources**: The Stoughton Diesel Alternative would not create a new or additional discharge to the Neponset River and Sprague Pond where the Northeast Corridor passes through the Fowl Meadow and Ponkapoag Bog ACEC. The Hockomock Swamp and Fowl Meadow ACECs would potentially be impacted by stormwater discharges to Black Brook and the East Branch of the Neponset River, respectively, from the Stoughton Diesel Alternative.

However, minimal impacts to ACECs from stormwater discharges would result from the project, and surface or groundwater resources within the ACECs would not be impaired.

- **Wetlands**: Potential permanent wetland and waterway impacts along the Stoughton Line include the loss of 1.7 acres within the Hockomock Swamp ACEC, out of a total of 8,260 acres of wetlands within this ACE.

Whittenton Electric Alternative

The Whittenton Electric Alternative (Figure 1.4-3) would comprise the elements listed in Table 4.10-7, which also summarizes the direct effects to protected open spaces and ACECs potentially resulting from implementing this alternative.

For the Whittenton Electric Alternative, approximately 0.66 acre of land would be acquired from protected open spaces. Legal access to protected open spaces and ACECs would not be significantly impacted by constructing, reconstructing, or using the railroad alignments, stations, or layover facilities.

Unauthorized access to protected open space and ACECs along the out-of-service portion of the Stoughton Line would cease.

The Whittenton Electric Alternative's impacts to ACEC key functions and values are summarized below:

- **Biodiversity**: The Whittenton Electric Alternative is expected to affect biodiversity in the Hockomock Swamp ACEC areas adjacent to the reconstructed track to a limited degree as a result of increased train traffic which would reduce habitat quality for some wildlife species and would create a partial barrier to wildlife movement. Although partially mitigated by the Hockomock Swamp Trestle, using this railroad bed would affect the connectivity of adjacent habitats and their overall biodiversity value, as described in Chapter 4.14.

- **Farmland soils**: The Whittenton Electric Alternative would impact designated farmland soils that occur at traction power station TPSS-1, located within the Hockomock Swamp ACEC. Construction of this site would impact 1.1 acres of designated farmland soils.

- **Historic and archaeological resources**: The Whittenton Electric Alternative would not affect known archaeological resources within any ACEC. This alternative, as a result of installing the overhead catenary system, would require construction in areas of moderate sensitivity for archaeological resources. This alternative would also require construction (installing pilings for the trestle) in areas of moderate sensitivity for archaeological resources. Additional investigation would be required to determine if any archaeological resources within the Hockomock Swamp ACEC would be affected.

- **Rare species**: The Whittenton Electric Alternative would potentially impact rare species habitat within the Hockomock Swamp ACEC and Three Mile River ACEC, as it crosses two Priority and Estimated Habitat polygons (PH1392/EH59 and PH261/EH153, respectively). This alternative would result in the loss of potential habitat to species known to be present within the Priority Habitats used by the eastern box turtle, Blanding's turtle and blue spotted salamander along either side of the right-of-way would be impacted by the construction of the railroad. The Hockomock Swamp ACEC provides habitat for at least 13 species listed as rare, endangered, or of special concern by the NHESP. Within the part of

the ACEC crossed by the Stoughton Alternative, four state listed species (blue-spotted salamander, Blanding's turtle, eastern box turtle, and gypsywort) are known to be present.

Table 4.10-7 Summary of Potential Direct Effects to Protected Open Spaces and ACECs from the Whittenton Electric Alternative

- **Water resources**: The Whittenton Electric Alternative would not create a new or additional discharge to the Neponset River and Sprague Pond where the Northeast Corridor passes through the Fowl Meadow and Ponkapoag Bog ACEC. The Hockomock Swamp and Fowl Meadow ACECs would potentially be impacted by stormwater discharges to Black Brook and the East Branch of the Neponset River, respectively, from the Whittenton Electric Alternative. However, minimal impacts to ACECs from stormwater discharges would result from the project, and surface or groundwater resources within the ACECs would not be impaired.

- **Wetlands**: Potential permanent wetland and waterway impacts along the Stoughton Line include the loss of 1.7 acres within the Hockomock Swamp ACEC, out of a total of 8,260 acres of wetlands within this ACEC.

Whittenton Diesel Alternative

The Whittenton Diesel Alternative would comprise the same elements as Whittenton Electric Alternative listed above (shown in Figure 1.4-3). Table 4.10-8 summarizes the direct effects to protected open spaces and ACECs potentially resulting from implementing this alternative.

For the Whittenton Diesel Alternative, approximately 0.16 acre of land would be acquired from protected open spaces. Legal access to protected open spaces and ACECs would not be significantly impacted by constructing, reconstructing, or using the railroad alignments, stations, or layover facilities.

Unauthorized access to protected open space and ACECs along the out-of-service portion of the Stoughton Line would cease.

The Whittenton Diesel Alternative's impacts to ACEC key functions and values are summarized below:

- **Biodiversity**: The Whittenton Diesel Alternative is expected to affect biodiversity in the Hockomock Swamp ACEC areas adjacent to the reconstructed track to a limited degree as a result of increased train traffic which would reduce habitat quality for some wildlife species and would create a partial barrier to wildlife movement. Although partially mitigated by the Hockomock Swamp Trestle, using this railroad bed would affect the connectivity of adjacent habitats and their overall biodiversity value, as described in Chapter 4.14.

- **Farmland soils**: The Whittenton Diesel Alternative would not impact any mapped areas of designated farmland soils within an ACEC.

- **Historic and archaeological resources**: The Whittenton Diesel Alternative would require construction (installing pilings for the trestle) in areas of moderate sensitivity for archaeological resources. Additional investigation would be required to determine if any archaeological resources within the Hockomock Swamp ACEC would be affected.

- **Rare species**: The Whittenton Diesel Alternative would potentially impact rare species habitat within the Hockomock Swamp ACEC and Three Mile River ACEC, as it crosses two Priority and Estimated Habitat polygons (PH1392/EH59 and PH261/EH153, respectively). This alternative would result in the loss of potential habitat to species known to be present within the Priority Habitats used by the eastern box turtle, Blanding's turtle and blue spotted salamander along either side of the right-of-way would be impacted by the construction of the railroad. The Hockomock Swamp ACEC provides habitat for at least 13 species listed as rare, endangered, or of special concern by the NHESP. Within the part of the ACEC crossed by the Stoughton Alternative, four state listed species (blue-spotted salamander, Blanding's turtle, eastern box turtle, and gypsywort) are known to be present.

- **Water resources**: The Whittenton Diesel Alternative would not create a new or additional discharge to the Neponset River and Sprague Pond where the Northeast Corridor passes through the Fowl Meadow and Ponkapoag Bog ACEC. Potential impacts to the Hockomock Swamp and Fowl Meadow ACECs would result from stormwater discharges to Black Brook and the East Branch of the Neponset River, respectively, from the Whittenton Diesel Alternative. However, minimal impacts to ACECs from stormwater discharges would result from the project, and surface or groundwater resources within the ACECs would not be impaired.

Table 4.10-8 Summary of Potential Direct Effects to Protected Open Spaces and ACECs from the Whittenton Diesel Alternative

Element/Component	Direct Effects: Acquisition Area (acres)	Direct Effects: Number of Parcels
Railroad Alignments		
Northeast Corridor	0	
Stoughton Line	0.16	1
Whittenton Branch	0	
Attleboro Secondary	0	
Fall River Secondary	0	
New Bedford Main Line	0	
Stations		
Canton Center	0	
Stoughton	0	
North Easton	0	
Easton Village	0	
Raynham Park	0	
Dana Street	0	
Taunton Depot	0	
Freetown	0	
Fall River Depot	0	
Battleship Cove	0	
King's Highway	0	
Whale's Tooth	0	
Layover Facility Alternatives		
Wamsutta Site	0	
Weaver's Cove East Site	0	
TOTAL	**0.16**	**1**

- **Wetlands**: Potential permanent wetland and waterway impacts along the Stoughton Line include the loss of 1.7 acres within the Hockomock Swamp ACEC, out of a total of 8,260 acres of wetlands within this ACEC.

Summary of Impacts

Table 4.10-9 provides a summary of the direct effects to protected open spaces and publicly owned parcels in ACECs for all alternatives.

Table 4.10-9 Summary of Potential Direct Effects to Protected Open Spaces and Publicly Owned Parcels in ACECs from All Alternatives

Alternative	Direct Effects: Acquisition Area (acres)	Direct Effects: Number of Parcels
Stoughton Electric	0.66	2
Stoughton Diesel	0.16	1
Whittenton Electric	0.66	2
Whittenton Diesel	0.16	1

The area of protected open space and publicly owned parcels within ACECs required for improving or constructing the alternatives is very similar among the alternatives. For all alternatives, the overall impact would be small relative to the total area of protected open space within the South Coast Rail

project area. All of the alternatives would impact considerably less than 0.01 percent of the total area of protected open space. The Stoughton Electric and the Whittenton Electric Alternatives would impact the same amount of protected open space, 0.66 acre. The Stoughton Diesel and Whittenton Diesel Alternatives would impact 0.5 acre less than their electric counterparts, or 0.16 acre.

4.10.3.6 Mitigation

Mitigation measures are categorized in order of preference: avoidance measures, intended to avoid direct impacts to a resource, are preferred. The second category of mitigation measures, minimization, accepts that direct impacts to the resource would occur, but uses engineering design or management controls to minimize the impact. The final level, mitigation, is used to offset direct impacts by compensating for the impact through some financial or physical analog for the impacted resource. In reality, some combination of these three measures would likely comprise a mitigation plan.

Each of these measures is considered, in turn, for each of the South Coast Rail alternatives in the following sections.

Avoidance

Measures taken to avoid impacts to protected open space and ACECs are described in the following subsections.

Common to All Build Alternatives

Conceptual engineering of the alternative alignments for the South Coast Rail project has focused upon using existing transportation corridors (in-service or out-of-service railroads, and in-service highways) to the extent practical. The rights-of-way established for these corridors do not encroach into protected open spaces. With few exceptions, the engineering design has avoided direct impacts to protected open spaces by delineating limits of work for the Build Alternatives within the rights-of-way.

Since publication of the DEIS/DEIR, acquisition requirements of Article 97-protected properties have been reduced by avoiding or minimizing encroachments into these properties. As listed in DEIS/DEIR Table 4.10-22, Summary of Article 97 Land Acquisition Requirements for All Alternatives, the Stoughton Electric Alternative at that time was projected to require acquisition of 1.09 acres of three Article 97-protected parcels. Based on the current level of design, the Stoughton Alternative would require the acquisition of a small (0.16 acre) portion of one parcel of Article 97-protected property. No other part of the railroad alignment and none of the stations or layover facilities would require acquisition of an Article 97-protected open space.

ACECs (as more geographically broad designations) generally include both disturbed and undisturbed areas, including transportation corridors such as the railroad and highway alignments considered for the South Coast Rail alternatives. Design options to avoid direct impacts to ACECs are therefore extremely limited, and would require extensive impractical re-routing of the alignments.

For the new station and layover facility alternatives, these sites were selected to specifically avoid direct impacts to protected open spaces or ACECs.[23] Expanding or reconstructing existing stations took into consideration adjacent protected open spaces to the extent practicable.

These types of impact avoidance efforts have been made for all alternatives. The following sections summarize the measures taken for each alternative to avoid direct impacts to protected open spaces and ACECs.

Stoughton Alternatives

The Stoughton Alternatives (Electric and Diesel) use existing in-service or out-of-service rail lines for the entire alignment; no new railroad alignments would be included in this alternative. Where the alignments pass through or are immediately adjacent to protected open spaces or ACECs, the limits of work for construction activities within each of these segments lie within the rights-of-way except for in a very few locations as described elsewhere in this section. Incursions into protected open spaces at these locations were minimized to the extent practicable.

The out-of-service segment of the Stoughton Line passes through the Hockomock Swamp ACEC and Pine Swamp protected open space. There are no practicable alternatives for this alignment that do not pass through these areas; however, only one publicly owned parcel within the ACEC would be acquired for a traction power facility for the Stoughton Electric Alternative. Traction power facilities must be sited within certain distances of power sources, based upon engineering constraints, and there are no feasible alternatives for the facility that would be located outside of the Hockomock Swamp ACEC. Sites for other traction power facilities were chosen to avoid any protected open space or ACECs.

The new station and layover facility sites were selected in part to avoid using protected open spaces or ACECs. None of the station or layover facility construction or operation activities would be within protected open spaces or ACECs.

Whittenton Alternatives

The Whittenton Alternatives (Electric and Diesel) use existing in-service or out-of-service rail lines for the entire alignment; no new railroad alignments would be included in this alternative. Where the alignments pass through or are immediately adjacent to protected open spaces or ACECs, the limits of work for construction activities within each of these segments lie within the rights-of-way except for in a very few locations as described elsewhere in this section. Incursions into protected open spaces at these locations were minimized to the extent practicable, as described in the Minimization section.

The out-of-service segment of the Stoughton Line passes through the Hockomock Swamp ACEC. There are no practicable alternatives for this alignment that do not pass through these areas; however, only one publicly owned parcel within this ACEC would be acquired for a traction power facility for the Whittenton Electric Alternative. As described above, traction power facility locations are constrained by engineering considerations, and sites for all other traction power facilities were chosen to avoid protected open spaces and ACECs. It should be noted that the Whittenton Alternatives do not use the southernmost portion of the Stoughton Line, thereby avoiding any impacts to the Pine Swamp protected open space.

[23] EOT. 2009. *Station Siting Report: EOT's Final Recommendations*. Commonwealth of Massachusetts, Executive Office of Transportation and Public Works. Prepared by Vanasse Hangen Brustlin, Inc.: Boston.

The new station and layover facility sites were selected in part to avoid using protected open spaces or ACECs, None of the existing station or layover facility construction or operation activities would be within protected open spaces or ACECs.

Minimization

Measures taken to minimize impacts to protected open space and ACECs are described in the following subsections.

Minimization Measures Common to All Build Alternatives

Minimizing direct impacts to protected open spaces and ACECs can be accomplished by applying engineering controls where encroachments into these areas are inevitable. For example, retaining walls may be constructed in areas of cut or fill to diminish the footprint of a slope that, if left at the angle of repose, would encroach into a protected open space. Some linear resources, such as streams or rivers, may be crossed by replacement bridges with one or two spans rather than the six or eight spans of the original bridge. These types of impact minimization efforts have been made for all alternatives at the conceptual design level evaluated in this section. Further impact minimization may result from final design of the selected alternative. The following sections summarize the measures taken for each alternative to minimize direct impacts to protected open spaces and ACECs.

Minimization Measures for the Stoughton Alternatives

Incursions into one of the two protected open spaces or publicly owned parcels in ACECs would be minimized along the Stoughton Electric Alternative alignment by reducing the footprint of the traction power facilities designated for installation at these locations. The second incursion at the Stoughton Memorial Conservation Land would be necessary in order to accommodate the western edge of the new road and an embankment sloping down from the road bed to the adjacent natural ground surface. Final engineering design, if one of these alternatives is selected, may further minimize, or avoid, these impacts.

Minimization Measures for the Whittenton Alternatives

Since publication of the DEIS/DEIR, refinements to the track design of the Whittenton Alternatives have eliminated the protected open space acquisition for the Whittenton Branch described in Section 4.10.3.2 of the DEIS/DEIR. The Whittenton Alternatives would have the same impacts on protected open space and ACECs as the Stoughton Alternatives. All of the incursions into protected open spaces for the Whittenton Alternatives are the same as those described above for the Stoughton Alternatives. Final engineering design, if one of these alternatives is selected, may further minimize, or avoid, these impacts.

Specific Mitigation Measures

Mitigation measures that may be taken to replace acquired parcels of protected open spaces or publicly owned parcels within ACECs are described below.

Mitigation Measures Common to All Build Alternatives

Current EEA policy requires directly mitigating impacts to publicly owned parcels within protected open spaces or ACECs, or privately owned protected open spaces covered by a conservation restriction, by

protecting an equivalent area (in both function and size). As described in Section 4.10.4.2, this policy applies to acquisition of parcels identified as Article 97 lands. Preferably, impacts to an area within a protected open space would be directly mitigated by acquiring and protecting a parcel adjoining the same protected open space. For example, if 0.5 acre of a protected open space would be acquired for the project, a separate 0.5-acre parcel adjoining that same open space, and providing similar functions as the lost area, would be purchased and given to the open space's owner to replace the lost functions of the area. If an equivalent parcel adjoining the affected parcel is not available, another area of equivalent (or greater) area and ecological value could be identified and acquired for conservation purposes, in accordance with applicable open space plans. In any case, there would be no net loss of the protected open space.

Mitigation Measures for the Stoughton Alternatives

Based upon the impacts indicated by conceptual engineering plans, direct mitigation for protected open spaces impacted by the Stoughton Alternatives would replace the lost functions for protected open spaces in the following municipalities:

Stoughton:

- 0.16 acre of Stoughton Memorial Conservation Land, in and owned by the Town of Stoughton; and

Easton (Electric Alternative only):

- 0.50 acre of conservation land in the Hockomock Swamp ACEC (consisting of 0.50 acre of the Southeast Regional Vocational Tech School sports fields), in and owned by the Town of Easton.

The parcel within the Hockomock Swamp ACEC would be used for a traction power substation for the Stoughton Electric Alternative and it would not be used for the Stoughton Diesel Alternative.

Mitigation Measures for the Whittenton Alternatives

Based upon the impacts indicated by conceptual engineering plans, direct mitigation for protected open spaces impacted by the Whittenton Alternatives would replace the lost functions for protected open spaces in the following municipalities:

Stoughton:

- 0.16 acre of Stoughton Memorial Conservation Land, in and owned by the Town of Stoughton; and

Easton (Electric Alternative only):

- 0.50 acre of conservation land in the Hockomock Swamp ACEC (consisting of 0.50 acre of the Southeast Regional Vocational Tech School sports fields), in and owned by the Town of Easton.

The parcel within the Hockomock Swamp ACEC would be used for a traction power substation for the Whittenton Electric Alternative and it would not be used for the Whittenton Diesel Alternative.

Summary

The South Coast Rail project alternatives would use existing railroad or highway alignments to the maximum extent possible, avoiding or minimizing impacts to protected open spaces. Where property acquisition of protected open spaces is necessary, direct mitigation would be required. Once the preferred alternative is selected and final design completed, such direct mitigation would be negotiated with the affected entity.

4.10.4 Regulatory Compliance

4.10.4.1 Introduction

This section summarizes the South Coast Rail project's compliance with regulations pertinent to open space, including Article 97 of the Massachusetts Constitution, the ACEC program, and Section 7 of the Wild and Scenic Rivers Act. Impacts to protected open spaces are regulated at the federal and state levels by both land management agencies and traditional regulatory agencies. None of the South Coast Rail alternatives require acquisition of any protected open spaces administered by a federal land management agency. Each alternative would require acquisition of protected open space administrated by the state or a municipality, or publicly owned parcels within an ACEC.

4.10.4.2 Article 97 of the Commonwealth of Massachusetts

The right of the Commonwealth's citizens to the quality of life that clean water and undeveloped open space can provide is mandated by Article 97 of the state constitution.[24] Article 97 of the Massachusetts Constitution provides that "[t]he people shall have the right to clean air and water, freedom from excessive and unnecessary noise, and the natural, scenic, historic, and esthetic qualities of their environment; and the protection of the people in their right to the conservation, development and utilization of the agricultural, mineral, forest, water, air and other natural resources is hereby declared to be a public purpose."[25]

The EEA has defined lands subject to Article 97 as "land or interests in … land owned or held by the Commonwealth or its political subdivisions"[26] that protect these interests. It is assumed that the publicly owned open spaces below that have been identified are Article 97 lands subject to the EEA Article 97 Land Disposition Policy.

The goal of the EEA Policy is to ensure no net loss of Article 97 lands. As a general rule, the EEA and its agencies "shall not sell, transfer, lease, relinquish, release, alienate, or change the control or use of any right or interest of the Commonwealth in and to Article 97 land."

Exceptions to this goal are included in the EEA Policy; disposition of Article 97 land is not supported unless exceptional circumstances exist. All other options to avoid use of Article 97 land must be explored and no feasible and substantially equivalent alternatives exist. The requirements for land disposition are

Accessed 17 June 2009.

[25] *Constitution of the Commonwealth of Massachusetts*, Article XCVII. Approved and ratified on November 7, 1972.

[26] EEA. *1998. Article 97 Land Disposition Policy.* Commonwealth of Massachusetts, Executive Office of Energy and Environmental Affairs, Massachusetts Environmental Policy Act Office: Boston.

summarized in the ACEC Program Requirements section, and the application to each alternative is provided in subsequent sections.

Requirements

The policy requires that EEA agencies minimize land disposition occurrences. All Article 97 land disposition proposals are to be coordinated with the EEA, and any Article 97 land disposition that is recommended must be justified and explained to the Secretary of the EEA. Any Article 97 land disposition must be authorized by enacted legislation and approved by all municipal, state, and federal agencies, authorities, or other governmental bodies as required and empowered.

According to the EEA Policy, Article 97 land disposition cannot be supported unless EEA and its agencies determine that exceptional circumstances exist. A determination of "exceptional circumstances" is subject to all of the following conditions being met:

- All other options to avoid the Article 97 disposition have been explored and no feasible and substantially equivalent alternatives exist;
- The disposition of the subject parcel and its proposed use do not destroy or threaten a unique or significant resource;
- As part of the disposition, real estate of equal or greater fair market value or value in use of proposed use, whichever is greater, and significantly greater resource value are granted to the disposing agency or its designee;
- The minimum acreage necessary for the proposed use is proposed for disposition and, to the maximum extent possible, the resources of the parcel proposed for disposition continue to be protected;
- The disposition serves an Article 97 purpose or another public purpose without detracting from the mission, plans, policies and mandates of EEA and its appropriate department or division; and
- The disposition of a parcel is not contrary to the express wishes of the person(s) who donated or sold the parcel or interests therein to the Commonwealth.

To the extent possible based upon readily available information and conceptual engineering plans, an evaluation of each alternative with respect to these six criteria is provided in the following subsections.

Regulatory Compliance of the Stoughton Alternatives

Portions of two protected open spaces and publicly owned land within one ACEC subject to the EEA Policy would be acquired for the Stoughton Alternatives. One of these parcels would be used for traction power substation for the Stoughton Electric Alternative. The Stoughton Alternatives' use of these Article 97 lands complies with the exceptional circumstances criteria as follows:

- **Alternatives**: The Stoughton Alternatives would use existing, active rail lines, as well as new rail lines on currently out-of-service railroad beds, and impacts to Article 97 lands have been avoided or minimized to the extent feasible. The other alternatives under consideration for

the South Coast Rail project (the Whittenton Alternatives) are substantially equivalent and have the same impacts to Article 97 lands.

- **Unique or Significant Resources**: Disposition of the two parcels for the Stoughton Alternatives would not destroy or threaten a unique or significant resource. For each of the parcels, the converted area represents a very small proportion of the overall protected area.

- **Real Estate and Resource Value**: An evaluation of the real estate and resource value of replacement sites would be completed if one of the Stoughton Alternatives is the selected alternative.

- **Minimum Acreage**: The final design of either of the Stoughton Alternatives, if selected, would minimize the acreage necessary for the proposed use and the resources of the parcel proposed for disposition would continue to be protected to the maximum extent possible.

- **Purpose**: The disposition of the parcels for the Stoughton Alternatives would serve a public transportation purpose without detracting from the mission, plans, policies and mandates of EEA and its appropriate department or division.

- **Intent**: If either of the Stoughton Alternatives is selected, the express wishes of the person(s) who donated or sold any acquired Article 97 parcel or interests therein to the Commonwealth would be investigated to ensure that the project complied with the original intent of the donation or sale.

Regulatory Compliance of the Whittenton Alternatives

Portions of two protected open spaces and publicly owned land within one ACEC subject to the EEA Policy would be acquired for the Whittenton Alternatives. As with the Stoughton Alternatives, one of these parcels would be used for traction power substation for the Whittenton Electric Alternative. The Whittenton Alternatives' use of these Article 97 lands complies with the exceptional circumstances criteria as follows:

- **Alternatives**: The Whittenton Alternatives would use existing, active rail lines, as well as new rail lines on currently out-of-service railroad beds, and impacts to Article 97 lands have been avoided or minimized to the extent feasible. The other alternatives under consideration for the South Coast Rail project (the Stoughton Alternatives) are substantially equivalent and have similar impacts to Article 97 lands.

- **Unique or Significant Resources**: Disposition of the two parcels for the Whittenton Alternatives would not destroy or threaten a unique or significant resource. For each of the parcels, the converted area represents a very small proportion of the overall protected area.

- **Real Estate and Resource Value**: An evaluation of the real estate and resource value of replacement sites would be completed if one of the Whittenton Alternatives is the selected alternative.

- **Minimum Acreage**: The final design of either of the Whittenton Alternatives, if selected, would minimize the acreage necessary for the proposed use and the resources of the parcel proposed for disposition would continue to be protected to the maximum extent possible.

- **Purpose**: The disposition of the parcels for the Whittenton Alternatives would serve a public transportation purpose without detracting from the mission, plans, policies and mandates of EEA and its appropriate department or division.

- **Intent**: If either of the Whittenton Alternatives is selected, the express wishes of the person(s) who donated or sold any acquired Article 97 parcel or interests therein to the Commonwealth would be investigated to ensure that the project complied with the original intent of the donation or sale.

Summary

Table 4.10-10 provides a comparison of the Article 97 land acquisition requirements for each South Coast Rail alternative. All of the South Coast Rail alternatives would require a minimal amount of Article 97 land acquisition (0.16 acre).

As described above, compliance with the Article 97 land disposition exceptional circumstances criteria would be completed for the selected alternative once the engineering design is finalized and replacement sites identified.

Table 4.10-10 Summary of Article 97 Land Acquisition Requirements for All Alternatives

	Article 97 Lands	
Alternative	Acquisition Area (acres)	Number of Parcels
Stoughton Electric	0.16	1
Stoughton Diesel	0.16	1
Whittenton Electric	0.16	1
Whittenton Diesel	0.16	1

4.10.4.3 ACEC Program

ACECs are "those areas within the Commonwealth where unique clusters of natural and human resource values exist and which are worthy of a high level of concern and protection."[27] ACECs are designated by the EEA, and the ACEC program is administrated by the Massachusetts Department of Conservation and Recreation. Projects within an ACEC that are subject to state agency jurisdiction or regulations are reviewed with closer scrutiny than other projects to avoid or minimize adverse environmental impacts to these unique areas.

Requirements

According to Commonwealth regulations,[28] all EEA agencies must take action, administer programs, and revise regulations in order to acquire useful scientific data on the ACEC; preserve, restore, or enhance the resources of the ACEC; and ensure that activities in or impacting on the ACEC are carried out so as to minimize adverse effects on seven environmental resources, as addressed in other chapters:

[27] EEA. 2009. 301 CMR 12.03 Areas of Critical Environmental Concern, General Provisions. Commonwealth of Massachusetts, Executive Office of Energy and Environmental Affairs: Boston.

[28] EEA. 2009. 301 CMR 12.12: Effects of Designation. Commonwealth of Massachusetts, Executive Office of Energy and Environmental Affairs: Boston.

- Marine and Aquatic Productivity: Chapter 4.18, *Chapter 91 Compliance and Coastal Zone Consistency*; Chapter 4.14, *Biodiversity, Wildlife, and Vegetation*; Chapter 4.15, *Threatened and Endangered Species*; Chapter 4.16, *Wetlands*; Chapter 4.17, *Water Resources*.
- Surface and Groundwater Quality: Chapter 4.17, *Water Resources*.
- Habitat Values: Chapter 4.14, *Biodiversity, Wildlife, and Vegetation*; Chapter 4.15, *Threatened and Endangered Species*.
- Storm Damage Prevention or Flood Control: Chapter 4.16, *Wetlands*.
- Historic and Archaeological Resources: Chapter 4.8, *Cultural Resources*.
- Scenic and Recreational Resources: Chapter 4.5, *Visual and Aesthetic Resources*.
- Other Natural Resource Values of the Area: Chapter 4.16, *Wetlands* and Chapter 4.11, *Farmland Soils*.

Each alternative's impact on any of the applicable resources at each publicly owned parcel within an ACEC is discussed in the following subsections.

Stoughton Alternatives

One publicly owned parcel within the Hockomock Swamp ACEC in Easton would be acquired for the Stoughton Alternatives:

- 0.50 acre of the Southeastern Regional Vocational Tech School sports fields.

This land would be used for a traction power substation for the Stoughton Electric Alternative. This area represents a small proportion of the ACEC and acquisition would not substantively affect any of the resource areas of concern.

Whittenton Alternatives

One publicly owned parcel within the Hockomock Swamp ACEC in Easton would be acquired for the Whittenton Alternatives:

- 0.50 acre of the Southeastern Regional Vocational Tech School sports fields.

This land would be used for a traction power substation for the Whittenton Electric Alternative. This area represents a small proportion of the ACEC and acquisition would not substantively affect any of the resource areas of concern.

Summary

Table 4.10-11 provides a comparison of the ACEC land acquisition requirements for each South Coast Rail alternative. As described above, none of the ACEC land acquisitions would substantively impact any of the resources of concern for the respective ACECs.

Table 4.10-11 Summary of ACEC Land Acquisition Requirements for All Alternatives

	ACEC Lands	
Alternative	Acquisition Area (acres)	Number of Parcels
Stoughton Electric	0.50	1
Stoughton Diesel	0	0
Whittenton Electric	0.50	1
Whittenton Diesel	0	0

A summary of each alternative's impacts to ACEC key functions is provided below:

- **Biodiversity**: The Stoughton and Whittenton Alternatives are expected to affect biodiversity in the Hockomock Swamp ACEC areas adjacent to the reconstructed track as a result of increased train traffic which would reduce habitat quality for some wildlife species and would create a barrier to wildlife movement. Although partially mitigated by the Hockomock Swamp Trestle, using this railroad bed would affect the connectivity of adjacent habitats and reduce their overall biodiversity value.

- **Farmland soils**: The Stoughton and Whittenton Electric Alternatives would impact designated farmland soils within the Hockomock Swamp ACEC at traction power station TPSS-1. Construction of this site would impact 1.1 acres of designated farmland soils. No farmland soils within an ACEC would be impacted by the Stoughton or Whittenton Diesel Alternatives.

- **Historic and archaeological resources**: None of the alternatives would affect known archaeological resources within any ACEC. The Stoughton and Whittenton Electric Alternatives, as a result of installing the overhead catenary system, would require construction in areas of moderate sensitivity for archaeological resources. The Stoughton and Whittenton Alternatives (both electric and diesel) would require construction (installing pilings for the trestle) in areas of moderate sensitivity for archaeological resources. Additional investigation would be required to determine if any archaeological resources within the Hockomock Swamp ACEC would be affected.

- **Rare species**: For the Stoughton and Whittenton Alternatives, approximately 22 acres of Priority and Estimated Habitat would be impacted within the Hockomock Swamp ACEC. Other species and their habitat may occur within the polygons or within the contiguous ACECs. There are no ACECs crossed by the Southern Triangle.

- **Water resources**: All Build Alternatives would discharge to the Neponset River and Sprague Pond where the Northeast Corridor passes through the Fowl Meadow and Ponkapoag Bog ACEC. Potential impacts to the Hockomock Swamp and Fowl Meadow ACECs would result from stormwater discharges to Black Brook and the East Branch of the Neponset River, respectively, from the Whittenton Diesel Alternative. However, minimal impacts to ACECs from stormwater discharges would result from the project, and surface or groundwater resources within the ACECs would not be impaired.

- **Wetlands**: The Stoughton and Whittenton Alternatives would potentially permanently impact 12.3 acres of waters of the United States along the Stoughton Line, including 1.9

acres of waterbodies/waterways and 10.4 acres of adjacent federal vegetated wetlands, as illustrated in Table 4.16-32. These waterbodies/waterways include the “stream” that diverted from its original course due to blockage and currently flows over the railroad grade south of Raynham Park. Relocating this stream to one side of the right-of-way would create impacts to 204 square feet of vegetated wetlands and over 1.5 acres of waterbodies/waterways to reconstruct the railroad and to construct Raynham Park Station. Mitigation measures would include re-establishing this stream’s original channel, resulting in a beneficial impact.

4.10.4.4 Wild and Scenic Rivers Act

Section 7 of the Wild and Scenic Rivers Act directs federal agencies to protect the free-flowing condition and other values of designated rivers.

Requirements

A determination under Section 7 is required for water resources projects (such as dams) proposed in the bed or banks of a designated river, or on a tributary to a designated river, if the project has federal involvement (e.g., is proposed, authorized, or funded by a federal agency) and, for projects in tributaries, if the project is likely to result in effects to a designated river.[29] These circumstances apply to the South Coast Rail project’s proposed replacement of the four bridges over the Taunton River and, potentially, the bridge over the tributary Mill River because of the requirement to obtain authorization from the Corps for the work under Section 404 of the Clean Water Act. Neither the Weaver’s Cove East Layover Facility nor the Fall River Depot Station are water resources projects and therefore are not subject to this evaluation.

Federally assisted water resources projects (such as bridge replacement) are prohibited only if they would have a “direct and adverse effect” on the values for which a river was added to the National System of Wild and Scenic Rivers. The determination standard for tributaries is applied to projects under the “invade the area or unreasonably diminish” standard. Based on these different standards, the evaluation of impacts to the Taunton River and the Mill River is provided below.

The effects of the project elements on the Taunton River are discussed first, followed by an evaluation of impacts on the Taunton River and Mill River, and discussion of the required consultation with NPS.

Taunton River

The main stem of the Taunton River was designated as a Wild and Scenic River on March 30, 2009.[30] The river’s designation is differentiated in four segments:

- The 18-mile segment from the confluence of the Town and Matfield Rivers to Route 24 in Raynham is designated as a scenic river;
- The 5-mile segment from Route 24 to 0.5 mile below Weir Bridge in Taunton is designated as a recreational river;
- The 8-mile segment from 0.5 mile below Weir Bridge to Muddy Cove in Dighton is designated as a scenic river; and

[29] Interagency Wild & Scenic Rivers Coordinating Council. 2004. Pg. 4.
[30] Omnibus Public Lands Management Act. Public Law 111-11. Section 5003. Taunton River, Massachusetts.

- The 9-mile segment from Muddy Cove to the confluence with the Quequechan River at the Route 195 bridge in Fall River is designated as a recreational river.

The following sections describe the impacts to the Taunton River from the bridges, layover facility, and station.

Bridges

Four bridges over the Taunton River and one bridge over the Mill River (a tributary to the Taunton River) would be replaced for the South Coast Rail project. The bridges are in Taunton (see Figure 4.10-23) and lie within a segment of the Taunton River designated as "recreational." The existing bridges are in deteriorating condition and have insufficient capacity for the expected loads and speeds of the South Coast Rail trains.

The bridges would be replaced with one- or two-span structures. The existing piles would be removed completely or to below grade. New cast-in-place concrete abutments would be constructed behind the existing abutments, which would then be wholly or partially removed to an elevation equal to the river's average seasonal high water elevation. The space between the existing and proposed abutments would be regraded to recreate the river banks on either side of the bridge. For the two-span bridges, a new, pile supported, cast-in-place concrete pier would be constructed in the center of the span. The Taunton River bridges would require approximately 1 year each to construct, while the Mill River bridge would require approximately 6 months to construct. The bridges must be constructed sequentially rather than simultaneously, in order to accommodate ongoing freight service.

The proposed new bridges would improve the navigational capacity and aesthetics along the rivers because of fewer, less visually intrusive pilings. The bridges would improve riparian conditions because they would be designed and constructed to meet Massachusetts River and Stream Crossing Standards, specifically by incorporating space along the river banks to allow wildlife passage. Stormwater runoff during bridge construction and railroad operation would be managed, and water quality in the Taunton and Mill Rivers would not be adversely impacted by stormwater runoff. The new bridges would not alter upland conditions nor change on-site conditions that would alter existing hydrologic or biologic processes. There would be no off-site changes that would affect the river system.

Replacing the bridges over the Taunton and Mill Rivers in Taunton would not adversely impact the recreational designation of the Taunton River in this reach.

Weaver's Cove East Layover Facility

The current level of design of the Weaver's Cove East layover facility incorporates stormwater management features in accordance with regulatory requirements. Constructing and operating a layover facility at the Weaver's Cove East site is not expected to result in any water quality impacts to the Taunton River from construction and stormwater runoff.

The segment of the Taunton River where the Weaver's Cove East Layover Facility is proposed has been designated as a "recreational river area," recognizing its low aesthetic value and developed shoreline. The Weaver's Cove East site is an undeveloped parcel on the east side of the existing active railroad. The shoreline in this segment is developed: a boat yard is north of the site and an industrial facility with a dock for fuel transfers is immediately south. Portions of the layover facility may be visible from the Taunton River, but are not expected to substantively change the visual environment from its current

condition. No impacts to the Taunton River are anticipated that would jeopardize its National Wild and Scenic River recreational designation in this reach.

Fall River Depot Station

The proposed Fall River Depot Station would be 1 mile north of downtown Fall River, on the west side of the Fall River Secondary rail line, between Pearce and Turner Streets on the north and south, respectively, and adjacent to North Davol Street on the west (see Figure 4.10-24).

The station site is visible from adjacent roads and nearby properties, and is within 750 feet of the Taunton River at its closest point, to the west. The intervening space is occupied by the State Route 79 and State Route 138 corridor and properties that have river frontage.

The current level of design of the station incorporates stormwater management features in accordance with regulatory requirements. Constructing and operating a station at the Fall River Depot site is not expected to result in any water quality impacts to the Taunton River; stormwater runoff would discharge to the Fall River sewer system.

This station is envisioned as a multi-modal transportation center with parking facilities. The 8-acre site is close to a dense residential neighborhood and an aging shopping plaza to the east. The station could catalyze redevelopment in that it offers a classic transit-oriented development opportunity that fits with the City of Fall River's plans for redeveloping the waterfront. The site is favorable from an environmental perspective as it was previously developed and does not contain wetlands, vernal pools, or priority habitats for rare species. It is not within the 100-year coastal floodplain.

The station would favorably affect the visual environment by replacing the existing vacant commercial buildings and parking lot with a new canopy, platform, and parking deck with 324 spaces. Its appearance would be an improvement compared to the existing vacant buildings and parking lots.

Constructing and operating the Fall River Depot Station would not detract from the recreational designation of the Taunton River in this reach and could enhance the city's waterfront area.

Taunton River Evaluation

Determining if a project would result in a direct and adverse effect to a designated river requires consideration of aspects of the project potentially impacting the river, and the scope of the evaluation should be consistent with the magnitude and complexity of the project. This section evaluates the potential impact to the Wild and Scenic River designation that may result from the proposed replacement of the Taunton River bridges, as required by Section 7.[31]

1. Define the proposed activity.

The project proponent, MassDOT, proposes to replace four bridges over the Taunton River because the existing bridges are in deteriorating condition and do not meet the safety and performance requirements for the South Coast Rail project. The four bridges are located in Taunton, Massachusetts, as shown on Figure 4.10-23. The bridge replacement project would require 4 years to complete and the bridges would be in operation indefinitely thereafter. The existing multi-span bridges, piers, and abutments would be removed; new abutments and superstructure would be installed. The replacement

[31] Interagency Wild and Scenic Rivers Coordinating Council. 2004. Appendix C: Evaluation Procedure Under "Direct and Adverse."

bridges would be one- or two-span structures. The riverbank would be graded to allow for wildlife passage.

2. Describe how the proposed activity will directly alter within-channel conditions.

The replacement activities would be conducted at the locations of the existing four bridges, largely within the footprint of the existing bridges. The new abutment locations, behind the existing abutment sites, would slightly extend the bridge length. There would be no changes to the active channel location, channel geometry, channel shape, channel form, or water quality parameters. Navigability of the river would be improved by replacing multi-span structures by one- or two-span structures. There would be no adverse impacts to outstanding resources values of the river channel.

3. Describe how the proposed activity will directly alter riparian and/or floodplain conditions.

New abutments would be constructed behind the existing abutments, expanding the riparian area and floodplain slightly. The riverbank at these locations would be re-graded consistent with the slope of the bank up- and downstream from the bridge location. The floodplain would be slightly expanded as a result of replacing the abutments. There would be no adverse impacts to outstanding resources values of the riparian area.

4. Describe how the proposed activity will directly alter upland conditions.

The project would not alter upland conditions. The work would be conducted within the existing railroad footprint, using rail-mounted equipment.

5. Evaluate and describe how changes in on-site conditions can/will alter existing hydrologic or biologic processes.

The project would not adversely alter existing hydrologic or biologic processes. All aspects of the bridge replacement would improve river flow characteristics by replacing the existing multi-span structures with one- or two-span bridges and moving the abutment locations up-bank. Potential impacts to water quality during construction would be managed in accordance with regulatory requirements of the National Pollutant Discharge Elimination System program, specifically described in a project-specific Stormwater Pollution Prevention Plan.

6. Estimate the magnitude and spatial extent of potential off-site changes.

There would be no off-site changes from the bridge replacement activities that would impact the river.

7. Define the time scale over which steps 3-6 are likely to occur.

The bridge construction activities are expected to require 4 years to complete. The bridges would be used indefinitely thereafter.

8. Compare project analyses to management goals.

The bridge replacements are not expected to adversely affect the achievement or timing of achievement of the management goals and objectives for the Taunton River, as described in the *Taunton River Stewardship Plan*.[32]

9. Make the Section 7 determination.

The bridge replacements would improve riparian area and floodplain conditions, and would not affect water quality, outstanding resources values, or the recreational river classification. Replacing and using four bridges over the Taunton River is not expected to result in a direct and adverse effect to the recreational nature of the Taunton River in this reach.

Mill River Evaluation

Determining if a project on a tributary to a designated river would adversely impact the Wild and Scenic River requires consideration of the proposed project's potential to either invade[33] the designated river or unreasonably diminish the scenic, recreational, fish, or wildlife values. This section evaluates the potential for the proposed replacement of the Mill River bridge to impact the Taunton River, as required by Section 7[34]:

The Mill River bridge replacement project activities would be similar to those described above for the Taunton River bridges: the work would be conducted largely within the footprint of the existing bridge and would not adversely impact any aspect of the river.

The evaluation requirement for tributaries is incorporated in this standard[35]:

> "Section 7(a) of the Act provides a specific standard for review of developments below or above or on a stream tributary to a designated river. Such developments may occur as long as the project "will not invade the area or unreasonably diminish the scenic, recreational, and fish and wildlife values present in the area as of the date of designation . . ." This standard applies to projects outside the river corridor but on the same river or a tributary."

The Mill River bridge is located approximately 1,250 feet upstream of the Mill River's confluence with the Taunton River. Given this distance and the construction activities summarized above, replacing the bridge would not encroach or intrude upon the Taunton River. The Taunton River in this segment is designated as "recreational." Replacing the Mill River bridge at a location 1,250 feet from the Taunton River that is not visible due to the winding river course and heavy vegetation would not diminish the recreational value of the Taunton River.

In summary, the Mill River bridge replacement project would not invade the Taunton River area or unreasonably diminish the recreational value of the Taunton River in this reach.

[33] "Invade" is defined as "encroach or intrude upon" by the US Department of Agriculture in regulations implementing Section 7, at 36 CFR 297.

[34] Interagency Wild and Scenic Rivers Coordinating Council. 2004. Appendix D: Evaluation Procedure Under "Invade the Area or Unreasonably Diminish.

[35] Ibid. Pg. 29.

Consultation

As explained in Chapter 4.5, *Visual and Aesthetic Resources* (Section 4.5.6.1), consultation with NPS is required. A meeting between MassDOT and representatives from the NPS Wild and Scenic Rivers Program was held in January 2012 to discuss the status of Taunton River as a National Wild and Scenic River. Detailed descriptions of the South Coast Rail project's potential impacts to the Taunton River from the proposed bridge replacement and Fall River Depot Station were requested. These are described above; and a discussion of impacts to the Taunton River, in the context of visual resources, is provided in Chapter 4.5 (Section 4.5.3.3). Further consultation with NPS is anticipated as the project advances through the design process.

4.11 FARMLAND SOILS

4.11.1 Introduction

This chapter discusses the presence of farmland soils that may be affected by the proposed South Coast Rail alternatives and associated stations and layover facilities. Section 4.11.1 provides general information relative to farmland soils, associated regulations, and state agricultural programs; Section 4.11.2 identifies the project study area, lists the farmland soils type, and describes existing farmland soils potentially affected by the South Coast Rail project; and Section 4.11.3 evaluates the specific impacts of each of the proposed alternatives to designated areas of mapped farmland soils. Background information on the proposed project and a summary of each of the proposed alternatives are provided in Chapter 3, *Alternatives*, and in the November 2008 ENF.[1]

This chapter addresses the requirements of the Certificate on the ENF, dated April 3, 2009, issued by the Secretary of the Executive Office of EEA. The Secretary's Certificate on the ENF required that the Draft EIR:

- The DEIR should include cumulative totals for land alteration and impervious area, as well as a breakdown for specific elements of the project such as stations and layover facilities.
- The DEIR should include a comparative analysis of land alteration for the alternatives, which should include a breakdown of the different types and amounts of land altered, for example: forest; woodland; wetland resource area (bordering vegetated wetlands, riverfront, bank, etc.); wetland buffer; priority habitat; previously disturbed area (specify land type/use).

The Secretary of the EAA issued a Certificate on the DEIR on June 29, 2011. No specific requirements for evaluation of farmland soils are included in the Certificate; however, the new Dana Street Station site was evaluated with respect to farmland soils.

Chapter 5, *Indirect Effects and Cumulative Impacts*, evaluates the potential effects of induced growth and cumulative losses of farmland soils in the South Coast region.

4.11.1.1 Resource Definition

Designated farmland soils are comprised of three classes of soils that have been identified by the USDA Natural Resources Conservation Service (NRCS): prime farmland, unique farmland, and farmland of statewide or local importance. These soil classes have been identified as contributing to the agricultural productivity of the country and should be protected from conversion to non-agricultural uses by federal programs.

Prime farmland is defined by the USDA NRCS as "land that has the best combination of physical and chemical characteristics" for agriculture. This includes land with these characteristics used for livestock or timber production, but not land that is already urbanized or used for water storage. Unique farmland is defined as "land other than prime farmland that is used for production of specific high value food and fiber crops," with such crops defined by the Secretary of Agriculture. Farmland of statewide or local

[1] Executive Office of Transportation and Public Works, South Coast Rail Environmental Notification Form, November 2008.

importance is defined as “farmland, other than prime or unique farmland, that is of statewide or local importance for the production of food, feed, fiber, forage, or oilseed crops.”

4.11.1.2 Regulatory Context

In 1981, the USDA passed the Farmland Protection Policy Act (FPPA)[2] to ensure that significant agricultural lands are protected from being converted to non-agricultural uses during federal programs. The determination of whether or not farmlands are subject to FPPA requirements is based on soil type and the land does not have to be actively used for agriculture. The FPPA regulates four types of farmland soils:

- Prime Farmland
- Unique Farmland
- Farmland of Statewide Importance
- Farmland of Local Importance

The USDA has adopted a policy of mitigating loss of farmland by any project that uses state funds, requiring the agency to replace the land or pay money into a local fund for preserving farmland. Massachusetts EO 193, Preservation of Agricultural Land, directs all state agencies to mitigate against the conversion of agricultural land to other uses when feasible alternatives are available.

4.11.1.3 State Agricultural Programs

This section provides an overview of the agricultural programs that are available in Massachusetts. Farmlands in southeastern Massachusetts are considered important because they play an important role in the local economy, keeping the taxes down, preventing sprawl, and maintaining the overall quality of life preferred by the local residents.[3]

Massachusetts Agricultural Preservation Restriction Program

The state’s Agricultural Preservation Restriction program (APR) is a voluntary program that encourages farmers to keep their land in active agricultural use. To alleviate development pressures on important pieces of agricultural land, the state provides funds for municipalities to pay an owner the difference between the fair market value and the “agricultural value” of the property in exchange for a permanent deed restriction that proscribes any use that would impair the property’s agricultural viability. Participation in the APR program is competitive, and APR funding is primarily allocated to communities that have demonstrated planning support for agricultural uses through tools such as right-to-farm bylaws and a commitment to smart growth principles.[4]

Almost two thirds of the South Coast region communities[5] along the southern section of I-495 (Bridgewater, Middleborough, Norton, Raynham, Taunton, and Wareham) and roughly one-third of the communities south of I-495, furthest away from Boston, (Fall River and New Bedford and the towns of

[2] United States Department of Agriculture, Farmland Protection Policy Act, 1981, (Public Law 97-98, 7 U.S.C. 4201).
[3] Southeastern Regional Planning and Economic Development District, Regional Open Space Plan, 2008.
[4] Ibid.
[5] This discussion of South Coast region communities reflects the conditions in the original study area during the DEIS/DEIR phase. It is inclusive of portions of the study area associated with alternatives no longer under consideration (i.e., the Attleboro and Rapid Bus Alternatives).

Acushnet, Dartmouth, Dighton, Fairhaven, Lakeville, Marion, Mattapoisett, Rehoboth, Rochester, Seekonk, Somerset, Swansea, and Westport) participate in the APR program. In the northern suburban communities closest to Boston (Attleboro, North Attleboro, Canton, Easton, Foxborough, Mansfield, Sharon, and Stoughton) only one community, Foxborough, participates. Dartmouth, Fairhaven, Norton, Rehoboth, Rochester, Taunton, and Westport all have used the program one or more times since 2000. Communities showing sustained participation in the program—Berkley, Dartmouth, Rehoboth, Rochester, and Westport—are semi-rural, with over 50 percent developable land and low amounts of permanently protected open space. With the exception of Westport, they also have experienced high rates of population growth since 1990. Continued participation in the APR program may allow these communities to protect important agricultural properties from suburbanization trends.

Regional Open Space Plan

A Regional Open Space Plan (ROSP) was developed by a committee of municipal representatives working with the SRPEDD to protect and preserve commonly shared land and resources in the Lower Taunton River Watershed.

As noted in the ROSP, these resources include some of the richest agricultural soils in the Taunton River Basin and some of the best examples of natural, aquatic, and estuarine resources in the region. For example, the riverfront lands along the Taunton River have some of the richest alluvial soils in the Commonwealth, and there are numerous farms along the river within the town of Berkley. Agriculture is the predominant land use in the towns of Berkley, Freetown, and Lakeville.[6] One strategy identified by the ROSP was to acquire and enroll farmland soils into APR programs.

Farm Viability Enhancement Program

The Farm Viability Enhancement Program is a state technical assistance program that works with farmers to provide a business plan for their operations. This program offers farmers financial assistance when they sign a short-term non-development agreement.[7]

Chapter 61A

Chapter 61A is an agricultural and horticultural land classification program designed to encourage the preservation of valuable farmland and promote active agricultural and horticultural land use in Massachusetts. It offers local tax benefits to property owners willing to make a long-term commitment to farming, by allowing agricultural lands of a least 5 continuous acres to be taxed at actual use value rather than at its development potential. In exchange for these benefits, when the land is removed from farming, the city or town in which the land is located is given the right to recover some of the tax benefits and an option to purchase the property if the land is sold or used for any other purpose than raising farm products.[8]

[6] Southeastern Regional Planning and Economic Development District, Regional Open Space Plan, 2008.
[7] Ibid.
[8] Massachusetts Department of Revenue, Division of Local Services Property Tax Bureau's "Taxpayer's Guide to Classification and Taxation of Agricultural/Horticultural Land in Massachusetts" Brochure dated October 1997. Chapter 61A. (http://www.charltontrust.org/Chapter_61A_brochure.htm).

4.11.2 Existing Conditions

4.11.2.1 Regional Overview of Existing Conditions

This section includes a general description of the South Coast Rail study area and lists the farmland soil types that may occur in the study area.[9]

Study Area

The South Coast area of Massachusetts is generally considered the region of southeastern Massachusetts within southern Bristol and Plymouth Counties, bordering on Buzzards Bay or Mount Hope Bay. The farmlands study area includes areas that are outside existing or inactive railroad or highway corridors, where construction could disturb or displace soils used for, or potentially used for, farming. Farmland soils and active farmlands were identified within portions of the proposed stations.

In order to evaluate farmland soils within the South Coast Rail study area, the NRCS soils data available through MassGIS were used to create maps of the alternatives that show the farmland soils at the station sites and a 100-foot buffer from the centerline of each existing and proposed alternative.

Farmland Soil Types

There are a total of 89 soil types that have been identified in Bristol County. Eighteen of these soils are considered prime farmland soils, two are considered farmland soils of unique importance (soil unit symbols 51A and 51B), and eight are considered farmland soils of statewide importance (soil unit symbols 254C, 255A, 255B, 256A, 305C, 306B, 306C, and 311B).

The importance of farmland soils classification is that it identifies the location and extent of the most suitable land for the production of food, feed, fiber, forage, and oilseed crops. This information is useful in the management, maintenance, and productive capacity of agriculture.[10] Table 4.11-1 lists the farmland soils that are identified by the NRCS Soil Survey in Bristol County.

4.11.2.2 Existing Conditions within the Study Corridor

This section lists and describes the farmland soils in areas of each project alternative that are currently undeveloped (station sites) or do not have existing transit infrastructure (rail corridors). All Build Alternatives are located along existing or abandoned right-of-ways that have been previously disturbed for transportation activities. Four of the station sites being proposed include areas that are identified as potentially important agricultural lands. Table 4.11-2 provides a list of proposed stations and whether or not designated farmland soils are present on those sites.

Southern Triangle (Common to All Build Alternatives)

Within the Southern Triangle study area, the Build Alternatives would all utilize existing segments of the right-of-way along the New Bedford Main Line and Fall River Secondary. Because these sections of the project would not incorporate land outside the existing railroad right-of-way, the presence of farmland soils adjacent to the rail right-of-way was not investigated. All Build Alternatives would include designated farmland soils at the proposed Freetown station site, as described below.

---

[9] The study area reflects the original study during the DEIS/DEIR phase and includes portions of the study area associated with alternatives no longer under consideration, including the Attleboro Alternative and the Rapid Bus Alternative.

[10] U.S. Department of Agriculture, Natural Resources Conservation Service, Soils (Farmland Classification). Website accessed on February 2009. (http://soils.usda.gov/technical/handbook/contents/part622.html#ex2).

Freetown Station Site—The approximately 18-acre Freetown station site is partially undeveloped and partially developed with an industrial land use. The developed portion is occupied by a self-storage business. The parcels surrounding the proposed station site are mainly forested, with some residential and industrial uses.

The Freetown station site includes areas of prime farmland soils (Figure 4.11-1). Table 4.11-3 lists the soil types, farmland classification, acreage, and percent coverage that are found within the Freetown station site (prime farmland is noted in bold).

Table 4.11-1 Prime and Unique Farmland Soils in Bristol County

Soil Unit	Soil Map Unit Name	Farmland Classification
51A	Swansea muck, 0 to 1 percent slopes	Farmland of unique importance
52A	Freetown muck, 0 to 1 percent slopes	Farmland of unique importance
223A	Scio silt loam, 0 to 3 percent slopes	Prime farmland
230A	Unadilla very fine sandy loam, 0 to 3 percent slopes	Prime farmland
230B	Unadilla very fine sandy loam, 3 to 8 percent slopes	Prime farmland
254A	Merrimac fine sandy loam, 0 to 3 percent slopes	Prime farmland
254B	Merrimac sandy loam, 3 to 8 percent slopes	Prime farmland
254C	Merrimac sandy loam, 8 to 15 percent slopes	Farmland of statewide importance
255A	Windsor loamy sand, 0 to 3 percent slopes	Farmland of statewide importance
255B	Windsor loamy sand, 3 to 8 percent slopes	Farmland of statewide importance
256A	Deerfield loamy fine sand, 0 to 5 percent slopes	Farmland of statewide importance
256B	Deerfield loamy sand, 3 to 8 percent slopes	Prime farmland
258A	Amostown fine sandy loam, 0 to 3 percent slopes	Prime farmland
260A	Sudbury fine sandy loam, 0 to 3 percent slopes	Prime farmland
260B	Sudbury fine sandy loam, 0 to 8 percent slopes	Prime farmland
275A	Agawam fine sandy loam, 0 to 3 percent slopes	Prime farmland
275B	Agawam fine sandy loam, 3 to 8 percent slopes	Prime farmland
276A	Ninigret fine sandy loam, 0 to 3 percent slopes	Prime farmland
305A	Paxton fine sandy loam, 0 to 3 percent slopes	Prime farmland
305B	Paxton fine sandy loam, 3 to 8 percent slopes	Prime farmland
305C	Paxton fine sandy loam, 8 to 15 percent slopes	Farmland of statewide importance
306B	Paxton fine sandy loam, 3 to 8 percent slopes, very stony	Farmland of statewide importance
306C	Paxton fine sandy loam, 8 to 15 percent slopes, very stony	Farmland of statewide importance
310A	Woodbridge fine sandy loam, 0 to 3 percent slopes	Prime farmland
310B	Woodbridge fine sandy loam, 3 to 8 percent slopes	Prime farmland
311B	Woodbridge fine sandy loam, 0 to 8 percent slopes, very stony	Farmland of statewide importance
325B	Newport silt loam, 3 to 8 percent slopes	Prime farmland
345B	Pittstown silt loam, 2 to 8 percent slopes	Prime farmland

The following sections summarize the NRCS soil descriptions of the prime farmland soil found at the Freetown station site.

Merrimac Sandy Loam (254B)[11]**—**This soil is gently sloping, deep, and somewhat excessively drained. It is adjacent to or near large streams and rivers. Areas of this soil are irregularly shaped and range from about 4 to 75 acres. Most are about 15 acres.

Table 4.11-2 Significant Farmland Soils found Within the Proposed Stations

Municipality	Station Name	Prime Farmland	Farmland of Unique Importance	Farmland of Statewide Importance
New Bedford	King's Highway	--	--	--
New Bedford	Whale's Tooth	--	--	--

Table 4.11-3 Freetown Station Site Soils

Soil Unit	Soil Map Unit Name	Farmland Classification	Impacted Acres	Percent Coverage
39A	Scarboro muck, 0 to 1 percent slopes	Not prime farmland	1.7	12
70A	Ridgebury sandy loam, 0 to 3 percent slopes	Not prime farmland	0.9	6
71B	Ridgebury sandy loam, 3 to 8 percent slopes, extremely stony	Not prime farmland	3.7	25
73A	Whitman loam, 0 to 3 percent slopes, extremely stony	Not prime farmland	0.5	3
254B	**Merrimac sandy loam, 3 to 8 percent slopes**	**Prime farmland**	**4.0**	**27**
260B	**Sudbury fine sandy loam, 0 to 8 percent slopes**	**Prime farmland**	**0.6**	**4**
310B	**Woodbridge fine sandy loam, 3 to 8 percent slopes**	**Prime farmland**	**2.4**	**17**
446B	Gloucester - Hinckley complex, undulating, very stony	Not prime farmland	0.8	6

This soil is suited to row crops. Droughtiness and an erosion hazard are the main limitations. Incorporating crop residue and manure into the surface layer helps to maintain or increase the organic matter content. The use of winter cover crops reduces surface runoff and helps reduce erosion.

The soil is suited to hay and pasture, especially to drought-resistant plants. The main management concern is the prevention of overgrazing, which causes surface compaction and reduces the density and hardiness of plants. Using proper stocking rates and restricted grazing during wet periods help to maintain plant densities and reduce surface compaction.

[11] USDA Soil Conservation Service. 1981. Soil Survey of Bristol County, Massachusetts (Southern Part).

This soil is suited to trees, but droughtiness causes a high rate of seedling mortality. Reducing plant competition and planting drought-resistant tree species help to reduce seedling mortality.

Sudbury Fine Sandy Loam (260B)[12]—This soil is gently sloping, deep, and moderately well drained. It is near or adjacent to streams and rivers. Areas of this soil are irregular in shape and range from 5 to 40 acres. Most are about 10 acres.

This soil is suited to row crops. The seasonal high water table is the main limitation, and erosion is a hazard. The main management practices include using drainage, using cover crops, and incorporating crop residue and manure into the surface layer to maintain the organic matter content.

The soil is suited to hay and pasture. The main management concerns are the prevention of overgrazing, the prevention of grazing when the soil is wet, and avoiding the use of equipment when the soil is wet, all of which reduce the hardiness and density of plants and cause surface compaction.

Woodbridge Fine Sandy Loam (310B)[13]—This soil is gently sloping, deep, and moderately well drained. It is on the tops and sides of hills. Areas of this soil are irregular in shape and range from 5 to 60 acres. Most are about 30 acres.

This soil is suited to row crops. A seasonal high water table is the main limitation, and erosion is a hazard. The main management practices include using drainage, using cover crops, and incorporating crop residue and manure into the surface layer.

The soil is well suited to hay and pasture. Use of proper stocking rates, deferred grazing, pasture rotation, and restricted grazing when the soil is wet help to maintain the hardiness and density of pasture plants and prevent surface compaction.

Stoughton Alternatives

The presence of farmland soils adjacent to the Northeast Corridor was not investigated because the potential construction associated with these sections of the project would only incorporate a narrow corridor of land adjacent to the existing railroad right-of-way. Because the New Bedford Main Line and Stoughton Line sections of the Stoughton Alternative would not incorporate land outside of the existing railroad right-of-way, the presence of farmland soils adjacent to the rail right-of-way was not investigated. Also, the out-of-service alignment along the Stoughton Line does not require soil analysis because it does not impact natural potentially farmland soils. The Stoughton Alternatives include farmland soils at the proposed Taunton Depot station site and at the North Easton station site. Neither of these sites is currently farmed.

Taunton Depot Station Site

The Taunton Depot station site is located at the rear of Target Plaza on Route 140. Although the site is currently undeveloped, half the site has been cleared while the other half remains forested. The 14-acre site is primarily surrounded by forest and undeveloped parcels to the north, west, and south. Target Plaza, east of the proposed station site, is a relatively new retail site that includes Target, Home Depot, and other stores.

[12] Ibid.
[13] USDA Soil Conservation Service. 1981. Soil Survey of Bristol County, Massachusetts (Southern Part).

The Taunton Depot station site includes areas of farmland soils of statewide importance (Figure 4.11-2). Table 4.11-4 lists the soil types, farmland classification, acreage, and percent coverage that are found within this station site (prime farmlands and farmlands of statewide or unique importance are shown in bold).

Table 4.11-4 Taunton Depot Station Site Soils

Soil Unit	Soil Map Unit Name	Farmland Classification	Impacted Acres	Percent Coverage
9A	Birdsall silt loam, 0 to 3 percent slopes	Not prime farmland	3.7	18
43A	Scarboro mucky loamy fine sand, 0 to 3 percent slopes	Not prime farmland	0.4	2
71B	Ridgebury sandy loam, 3 to 8 percent slopes, extremely stony	Not prime farmland	0.9	4
73A	Whitman loam, 0 to 3 percent slopes, extremely stony	Not prime farmland	0.5	3
245B	Hinckley sandy loam, 3 to 8 percent slopes	Not prime farmland	6.6	32
256A	**Deerfield loamy fine sand, 0 to 5 percent slopes**	**Farmland of statewide importance**	**7.1**	**35**
409B	Charlton - Paxton fine sandy loams, 3 to 8 percent slopes	Not prime farmland	1.1	6

Deerfield Loamy Fine Sand (256A)[14]—This soil is deep, nearly level and gently sloping, and moderately well drained. It is on outwash plains. Slopes are smooth or gently undulating and are 100 to 600 feet long. They are generally less than 3 percent but range to 6 percent in some places. The mapped areas are irregular in shape and are 5 to 40 acres in size.

This soil has fair to poor potential for farming. The soil has good potential for trees and fair potential for open land wildlife habitat. Most acreage is wooded. Some acreage is farmed.

The soil has limited suitability for farming because of the restricted root zone and low available water capacity. The seasonal high water table is the major concern of management. Fertilizer nutrients are quickly leached away by rapidly percolating water. The hazard of erosion is slight. Conservation management includes frequent irrigation and application of fertilizer, addition of organic matter to the plow layer, and use of cover crops.

North Easton Station Site

The North Easton station site is located off Route 138 in Easton. The proposed station site is adjacent to an approximately 10-acre retail plaza anchored by a Roche Brothers supermarket, which includes commercial and offices uses. The station site is currently undeveloped; although some of the site has been cleared, the majority remains forested. New medical buildings have recently been constructed and two additional buildings are planned on the larger site. The North Easton station site is surrounded by forest and undeveloped land.

The North Easton station site includes areas of prime farmland soils and farmland soils of statewide importance (Figure 4.11-3). Table 4.11-5 lists the soil types, farmland classification, acreage, and percent coverage that are found within the North Easton station site.

[14] USDA Soil Conservation Service. 1978. Soil Survey of Bristol County, Massachusetts (Northern Part).

Table 4.11-5 North Easton Station Site Soils

Soil Unit	Soil Map Unit Name	Farmland Classification	Impacted Acres	Percent Coverage
73A	Whitman loam, 0 to 3 percent slopes, extremely stony	Not prime farmland	0.1	1
245C	Hinckley sandy loam, 8 to 15 percent slopes	Not prime farmland	0.2	3
254B	**Merrimac sandy loam, 3 to 8 percent slopes**	**Prime farmland**	**3.3**	**57**
306C	**Paxton fine sandy loam, 8 to 15 percent slopes, very stony**	**Farmland of statewide importance**	**0.9**	**15**
310B	**Woodbridge fine sandy loam, 3 to 8 percent slopes**	**Prime farmland**	**1.5**	**25**

Merrimac sandy loam (254B) and Woodbridge fine sandy loam (310B) were previously described for the Freetown Station site. The following sections summarize the NRCS soil descriptions of the other prime farmland soils found at the North Easton station site.

Paxton Very Stony Fine Sandy Loam (306C)[15]—This soil is deep, moderately sloping, and well drained. It is generally on side slopes of drumloids. Slopes are smooth and convex, and are generally 200 to 400 feet long. Stones are scattered over the surface 20 to 50 feet apart. The mapped areas are irregularly shaped and are 10 to 40 acres in size.

Permeability is moderate or moderately rapid in the subsoil and moderately slow or slow in the substratum. The available water capacity is moderate. The root zone extends to a depth of about 27 inches. Root growth is hampered by the very firm substratum. Reaction is very strongly acid to slightly acid. A seasonal high water table is perched above the substratum for brief periods in winter and spring.

This soil is poorly suited to farming. It is mainly in unimproved pasture. This soil has good potential for trees and for woodland wildlife habitat. Most acreage is in woodland. The soil is not suited to cultivated crops because of stones on the surface. Proper stocking rates, deferred grazing, and pasture rotation are management practices that help to maintain desirable pasture plants. The soil is well suited to trees. Productivity is moderate. Important tree species are northern red oak and eastern white pine.

Prime farmland classification appears to be associated with soil units of the Paxton Series that do not contain significant amounts of stone deposits and are suitable for cropping.

Whittenton Alternatives

The presence of farmland soils adjacent to the Northeast Corridor was not investigated because the potential construction associated with these sections of the project would only incorporate a narrow corridor of land adjacent to the existing railroad right-of-way. Because the New Bedford Main Line, Stoughton Line, Whittenton Branch and Attleboro Secondary sections of the Whittenton Alternatives would not incorporate land outside of the existing railroad right-of-way, the presence of farmland soils adjacent to the rail right-of-way was not investigated. Also, the out-of-service alignment along the Stoughton Line does not require soil analysis because it does not impact natural potentially farmland soils. The Whittenton Alternatives include farmland soils at the proposed North Easton station site and at the Taunton Depot station site as discussed above for the Stoughton Alternatives.

[15] USDA Soil Conservation Service. 1978. Soil Survey of Bristol County, Massachusetts (Northern Part).

Dana Street Station Site

The Dana Street station site comprises approximately 4.9 acres and is located along an existing active freight rail right-of-way. The site is currently a degraded, undeveloped area and consists mainly of bare earth with no vegetation and signs of heavy use by off road vehicles. Several piles of debris are also present. The site is not currently farmed, part of an active farm, or adjacent to an active farm.

The Dana Street station site includes areas of farmland soils of statewide importance (Figure 4.11-4). Table 4.11-6 lists the soil types, farmland classification, acreage, and percent coverage that are found within the site. Deerfield loamy fine sand was described above for the Taunton Depot Station site.

Table 4.11-6 Dana Street Station Site Soils

Soil Unit	Soil Map Unit Name	Farmland Classification	Impacted Acres	Percent Coverage
602	Urban land	Not prime farmland	3.5	72%
32A	Wareham loamy fine sand, 0 to 3 percent slopes	Not prime farmland	1.2	24%
256A	Deerfield loamy fine sand, 0 to 5 percent slopes	Farmland of statewide importance	0.2	4%

Layover Facilities Study Areas

Two preferred rail layover facilities have been identified for the rail alternatives, the Wamsutta Site and Weaver's Cove East. No designated farmland soils are present at the Wamsutta Site in New Bedford or at Weaver's Cove East in Fall River. Since mid-day rail layover facility sites are being separately evaluated as part of the South Station Expansion Project, potential sites have not been identified at this time.

4.11.2.3 Summary of Existing Conditions

The Build Alternatives that are being evaluated would be constructed almost entirely within the footprint of existing or out-of-service rail corridors. As a result, there are no active farms or undisturbed farmland soils associated with the rail or highway corridors included in these alternatives. Designated farmland soils do occur at some proposed station sites.

Most of the station sites would be located within developed and urbanized areas. Four station sites have been mapped with farmland soils present: Freetown, Taunton Depot, North Easton and Dana Street. Soils mapping may vary from field conditions, and is not designed for use as a primary regulatory tool, but may be used as a reference source.[16] None of these sites are currently being farmed. Alternatives that include sites with designated farmland soils include the following:

- Freetown Station Site – all Build Alternatives
- Taunton Depot Station Site – Stoughton Alternatives
- North Easton Station Site – all Build Alternatives

[16] MassGIS-NRCS SSURGO-Certified Soils. http://www.mass.gov/anf/research-and-tech/it-serv-and-support/application-serv/office-of-geographic-information-massgis/datalayers/soi.html.

- Dana Street Station Site – Whittenton Alternatives

None of the above sites are currently farmed, part of an active farm, or adjacent to an active farm, and are not anticipated to be included in an Agricultural Preservation Restriction program or Chapter 61A program.

4.11.3 Analysis of Impacts

4.11.3.1 Introduction

This section evaluates the specific impacts of each of the proposed alternatives to designated areas of mapped farmland soils. It explains the methodology for evaluating direct and indirect impacts to farmland soils, identifies specific locations where impacts to farmland soils would occur under each alternative, summarizes the impacts that would be anticipated under each alternative, and also discusses regulatory compliance measures that would be required once a preferred alternative is selected.

4.11.3.2 Impact Assessment Methodology

Method for Assessing Direct Impacts

Direct impacts are losses that involve open or forested lands, including active farmland, that include designated farmland soils. Direct impacts to farmland soils were calculated using GIS software to overlay the project limits of work on soil units mapped by the available NRCS soil survey as prime farmland, unique farmland, or farmland soils of statewide importance (farmland soils). Activities proposed within soil map units designated as farmland soils that have been previously converted to transportation corridors (road or railroad) or other irretrievable uses were considered to be previously impacted and were ignored for the purposes of this assessment.

The ultimate determination of the severity of a farmland impact is characterized by the total score calculated using the USDA's Farmland Conversion Impact Rating forms AD-1006 (for site impacts) and CPA-106 (for corridor-type impacts). These forms must be completed cooperatively with the NRCS. The forms assess the severity of a farmland impact on a scale of 260 points, with 160 points determined by a site assessment and 100 points determined by the NRCS itself. A score of less than 160 is considered negligible and requires no further analysis. A score between 160 and 200 indicates potential impacts, and the project should consider measures to minimize farmland impacts. A score of 200 or higher indicates a significant impact.

For the purpose of this evaluation, it was conservatively assumed that the NRCS would assign the maximum relative value of 100 for Part V of the Farmland Conversion Impact Rating. This would provide maximum impact ratings between 120 and 134 at the station sites and layover facilities . None of the calculated ratings exceed 200, therefore the impacts would not be considered significant by the NRCS. Draft Farmland Conversion Impact Rating Forms AD-1006 and CPA-106 are provided in Attachment A. After an alternative has been selected for advancement to the Final EIR, forms describing impacts to farmland soils associated with that alternative would be submitted to the NRCS for completion.

Draft forms for sites and corridor segments that would potentially impact more than 2 acres of mapped farmland soils were completed in order to determine the severity of impact. Copies of these forms are included in Appendix 4.11-A.

Method for Assessing Indirect Impacts

Indirect impacts are consequences that occur as the result of an action's direct impact. Indirect impacts, as defined on NRCS Forms AD-1006 and CPA-106, may include reducing or eliminating access to farmland, reducing farmland to a size or configuration that is no longer viable, effects on local farm support services and industries, and proximity to improvements such as water and sewer lines. Indirect impacts were evaluated considering the direct impacts to the farmland, the criteria used in the farmland rating for Form AD-1006 and Form CPA-106, as well as subsequent development or development pressure that may result from the direct impacts.

4.11.3.3 Impacts of Alternatives by Element

This section evaluates the potential impacts to farmland soils associated with the project alternatives that are being advanced for consideration. These alternatives include the No-Build Alternative (Enhanced Bus), Stoughton Alternatives (Electric and Diesel), and Whittenton Alternatives (Electric and Diesel).

No-Build (Enhanced Bus) Alternative

The No-Build Alternative (Enhanced Bus) would consist of enhancing current bus service along existing roads and highways. Three existing park-and-ride facilities would be modified as part of the No-Build Alternative:

- West Bridgewater Park-and-Ride, located near the southwest corner of the intersection of Routes 106 and 24;
- Mount Pleasant Street Park-and-Ride, located on the northwest corner of the intersection of King's Highway and Route 140 in New Bedford;
- Galleria Park-and-Ride, located adjacent to the Silver City Galleria shopping mall in Taunton.

None of these sites are within mapped areas of designated farmland soils. Under the No-Build Alternative, minor modifications are proposed to these existing parking lots that would not disturb additional land. No impacts to farmland soils are anticipated under the No-Build Alternative.

Southern Triangle (Common to All Build Alternatives)

All Build Alternatives would use existing segments of the railroad right-of-way along the New Bedford Main Line and Fall River Secondary (together referred to as the Southern Triangle). Because these sections of the project would not incorporate land outside of existing and active railroad right-of-ways, the presence of farmland soils along these corridors was not investigated. All Build Alternatives include impacts to designated farmland soils at the proposed Freetown station site, adjacent to the Fall River Secondary in Freetown.

Stoughton Electric Alternative

The alignment of the proposed Stoughton Alternative follows a previously developed railroad corridor. Although the rail corridor has been abandoned, the prior alteration of soils and placement of fill materials results in the corridor not being available for farming activities. Minor temporary and permanent impacts may occur within sliver takings immediately adjacent the right-of-way during track reconstruction and re-alignment; however, none of these areas are actively farmed or would constitute

farmable land by themselves. The North Easton station site proposed as part of this alternative would impact mapped areas of designated farmland soils. This station site is located adjacent to the rail corridor in Easton and Stoughton. Impacts at proposed station sites are described below.

Under the Stoughton Electric Alternative, alteration of mapped areas of designated farmland soils would occur at traction power stations located adjacent to the existing right-of-way and constitute the impact to farmland soils associated with this alternative. Four of the ten traction power stations associated with the electric alternative are located on sites that include mapped areas of designated farmland soils. These impacts are identified in Table 4.11-7.

Table 4.11-7 Impacts to Designated Farmland Soils–Stoughton Alternative Traction Power Stations

Municipality	Station Name	Prime Farmland (acres)	Farmland of Unique Importance (acres)	Farmland of Statewide Importance (acres)
Stoughton	Stoughton PS-1	0.3	--	--
Canton	Stoughton SWS-2	0.4	--	--
Easton	Stoughton TPSS-1	0.6	--	0.5
New Bedford	Stoughton TPSS-2	0.8	--	--
	Total	2.1	--	0.5

Traction Power Station TPSS-1 is located within the Hockomock Swamp ACEC. Construction at this site would alter a total of 1.1 acres of designated farmland soils: 0.6 acre of Ninigret fine sandy loam, 0 to 3 percent slopes, a soil designated as a Prime Farmland Soil, and 0.5 acre of Windsor loamy sand, 3 to 8 percent slopes, a soil designated as a Farmland Soil of Statewide Importance. However, this area is not actively farmed.

Figures 4.11-5, 4.11-6, 4.11-7, and 4.11-8 illustrate the areas of mapped farmland soils that would be impacted by these traction power stations. Because all of the proposed traction power stations are less than 2 acres in size, drafts of Form AD-1006 were not completed for these locations.

Stoughton Diesel Alternative

Impacts to mapped areas of designated farmland soils for the Stoughton Diesel Alternative are limited to any minor sliver takings along the existing railroad corridor. The diesel alternative involves 2.6 acres less impact than the electric alternative because no traction power stations are proposed under the diesel alternative.

Whittenton Electric Alternative

The alignment of the proposed Whittenton Electric Alternative follows previously developed railroad corridors along the Attleboro Secondary, Whittenton Branch, and Stoughton Line. Although the Whittenton Branch and portions of the Stoughton Line have been abandoned, the prior alteration of soils and placement of fill materials results in the corridor not being available for farming activities. Minor temporary and permanent impacts may occur within sliver takings immediately adjacent the right-of-way during track reconstruction and re-alignment; however, none of these areas are actively farmed or would constitute farmable land. The North Easton, Taunton Depot and Dana Street station sites proposed as part of this alternative would impact mapped areas of designated farmland soils. The North Easton station site is located adjacent to the rail corridor in Easton and Stoughton. The Taunton

Depot station site is located adjacent to the New Bedford Main Line in Taunton. The Dana Street station site is located just south of the Danforth Street grade crossing, within walking distance of downtown Taunton. Impacts at proposed station sites are described in the section on Stations.

Under the Whittenton Electric Alternative, alteration of mapped areas of designated farmland soils would occur at 10 traction power stations located adjacent to the existing right-of-way and constitute the impact to farmland soils associated with this alternative. With one exception (PS-2), the traction power stations associated with the Whittenton Electric Alternative are the same as those in the Stoughton Electric Alternative and result in the same impacts presented in Table 4.11-7. The location of Whittenton Electric Alternative traction power station PS-2 does not include mapped areas of designated farmland soils. Figures 4.11-5, 4.11-6, 4.11-7, and 4.11-8 illustrate the areas of mapped farmland soils that would be impacted by these traction power stations. Because all of the proposed traction power stations are less than 2 acres in size, drafts of Form AD-1006 were not completed for these locations.

Whittenton Diesel Alternative

Impacts to mapped areas of designated farmland soils for the Whittenton Diesel Alternative are limited to any minor sliver takings along the existing railroad corridor. The diesel alternative involves 2.6 acres less impact than the electric alternative because no traction power stations are proposed under the diesel alternative.

Stations

Four proposed station sites are located in areas with mapped farmland soils. These station sites include Freetown, North Easton, Taunton Depot and Dana Street. Table 4.11-8 identifies proposed station sites that include impacts to designated farmland soils.

Table 4.11-8 Impacts to Designated Farmland Soils–Proposed Station Sites

Station Name	Municipality	Prime Farmland (acres)	Farmland of Unique Importance (acres)	Farmland of Statewide Importance (acres)
Freetown	Freetown	3.0	--	--
North Easton	Easton & Stoughton	6.9	--	0.4
Taunton Depot	Taunton	--	--	5.7
Dana St. Station	Taunton	--	--	0.2

Drafts of AD-1006 (Farmland Conversion Impact Rating) forms for each station site are included in Appendix 4.11-A.

Freetown Station

The Freetown station site is located on South Main Street in Freetown and would serve all Build Alternatives. The South Main Street frontage of the site has been developed for industrial use as a self-storage facility and cellular phone tower. The remainder of the approximately 18-acre site has been cleared of trees, but does not appear to be in agricultural production. Parcels surrounding the proposed station site are mainly forested, with some residential and industrial uses.

The Freetown station site includes areas of prime farmland soils. Mapped areas of designated farmland soils that would be impacted by the development of this station site (3 acres) are shown on Figure 4.11-1. In accordance with the assessment procedure outlined on USDA Form AD-1006, the site scores 128 out of a total of 260 points. This low score indicates that the site has relatively low agricultural value and the conversion of the site would be consistent with the FPPA.

North Easton Station

The North Easton station site is located off Route 138 in Easton and would serve all Build Alternatives. The proposed station site is approximately 8.8 acres in size and is adjacent to a 10-acre retail development that is anchored by a Roche Brothers supermarket. The station site is currently undeveloped and mostly forested. Although some of the site has been cleared, it does not appear to be in agricultural production. New medical buildings have recently been constructed and two additional buildings are planned on the larger site. Other than the commercial and offices uses at the shopping plaza, the site is surrounded by forest and undeveloped land.

The North Easton station site includes areas of prime farmland soils and farmland soils of statewide importance. Mapped areas of designated farmland soils that would be impacted by the development of this station site (7.3 acres) are shown on Figure 4.11-3. In accordance with the assessment procedure outlined on USDA Form AD-1006, the site scores 134 out of a total of 260 points. This low score indicates that the site has relatively low agricultural value and the conversion of the site would be consistent with the FPPA.

Taunton Depot Station

The Taunton Depot station site is located at the rear of Target Plaza on Route 140 and would serve all Build Alternative. Although the site is currently undeveloped, roughly half the site has been cleared of trees. The approximately 14-acre site is primarily surrounded by forest and undeveloped parcels to the north, west, and south. Target Plaza, east of the proposed station site, is a retail site that includes Target, Home Depot, and other stores.

The Taunton Depot station site includes areas of farmland soils of statewide importance. Mapped areas of designated farmland soils that would be impacted by the development of this station site (5.7 acres) are shown on Figure 4.11-2. In accordance with the assessment procedure outlined on USDA Form AD-1006, the site scores 120 out of a total of 260 points. This low score indicates that the site has relatively low agricultural value and the conversion of the site would be consistent with the FPPA.

Dana Street Station

The Dana Street Station site is located just south of the Danforth Street grade crossing, within walking distance of downtown Taunton and would serve the Whittenton Alternatives. The approximately 4.9-acre site is a currently vacant lot that appears to have been in industrial use, although it is zoned for residential use. The area is not currently farmed and is a degraded undeveloped area. The area surrounding the site is densely developed with land uses including commercial, industrial, and residential properties.

The Dana Street station site includes farmland soils of statewide importance. Mapped areas of designated farmland soils that would be impacted by the development of this station site (0.2 acre) are shown on Figure 4.11-4. In accordance with the assessment procedure outlined on USDA Form AD-1006,

the site scores 15 out of a total of 260 points. This low score indicates that the site has relatively low agricultural value and the conversion of the site would be consistent with the FPPA.

Layover Facilities

Two preferred rail layover facilities have been identified and evaluated for potential impacts to mapped areas of designated farmland soils. No designated farmland soils are present at the Wamsutta Street layover site in New Bedford, or at the Weaver's Cove East site in Fall River.

One mid-day rail layover facility is planned for the Boston area, but alternative sites have not been selected. Regardless, it is expected that this facility would not impact farmland soils because it would be in or near an already developed area, and is likely not to be within an area used for agriculture.

4.11.3.4 Summary of Impacts by Alternative

This section summarizes the potential impacts to mapped areas of designated farmland soils for each of the alternatives. No information is currently available about potential impacts to farmland soils at the mid-day layover facility. Based on the conservative assessment used to complete the NRCS forms, no significant impacts are anticipated for designated farmland soils that would be altered by this project. Table 4.11-9 summarizes the impacts for each alternative prior to the addition of potential mid-day layover facility impacts.

Table 4.11-9 Impacts to Designated Farmland Soils by Alternative (acres)

Alternative	Southern Triangle	Northern Element	Stations	Total
No-Build/Enhanced Bus Alternative	--	--	--	0
Stoughton Electric Alternative	--	2.6	16.0	18.6
Stoughton Diesel Alternative	--	--	16.0	16.0
Whittenton Electric Alternative	--	2.6	16.2	18.8
Whittenton Diesel Alternative	--	--	16.2	16.2

Stoughton Electric Alternative

The Stoughton Electric Alternative would result in impacts to 18.6 acres of designated farmland soils. Much of this impact occurs as a result of development of the North Easton station site (7.3 acres). The remaining impacts occur as a result of the traction power stations associated with the electrification of the Stoughton Line and the development of the Freetown station site. One of the traction power stations (TPSS-1) is located within the Hockomock Swamp ACEC and would impact 1.1 acres of designated farmland soils.

Using the USDA scoring system, the impacts to farmland soils along this alternative all received low scores. Such scores indicate that these impacts would not be considered significant under the FPPA, and that mitigation for these losses would not be required.

Stoughton Diesel Alternative

The Stoughton Diesel Alternative would result in impacts to 16 acres of designated farmland soils. This impact is slightly less than the electrification alternative because there are no traction power stations

required along the Stoughton Line under the diesel alternative. The remaining impacts occur due to development of the North Easton and Freetown station sites.

Using the USDA scoring system, the impacts to farmland soils along this alternative all received low scores. Such scores indicate that these impacts would not be considered significant under the FPPA, and that mitigation for these losses would not be required.

Whittenton Electric Alternative

The Whittenton Electric Alternative would result in impacts to 18.8 acres of designated farmland soils, the largest impact to farmland soils of all of the alternatives. Much of this impact occurs as a result of development of the North Easton and Taunton Depot station sites (7.3 and 5.7 acres, respectively). The remaining impacts occur as a result of the traction power stations associated with the electrification of the Stoughton Line and the development of the Freetown station site and the Dana Street Station site. One of the traction power stations (TPSS-1) is located within the Hockomock Swamp ACEC and would impact 1.1 acres of designated farmland soils.

Using the USDA scoring system, the impacts to farmland soils along this alternative all received low scores. Such scores indicate that these impacts would not be considered significant under the FPPA, and that mitigation for these losses would not be required.

Whittenton Diesel Alternative

The Whittenton Diesel Alternative would result in impacts to 16 acres of designated farmland soils. This impact is 2.6 acres less than for the Whittenton Electric Alternative, because no traction power stations would be required for the diesel alternative.

Using the USDA scoring system, the impacts to farmland soils along this alternative all received low scores. Such scores indicate that these impacts would not be considered significant under the FPPA, and that mitigation for these losses would not be required.

4.11.3.5 Regulatory Compliance

Farmland Protection Policy Act

The FPPA, P.L. 9798, authorizes the USDA to develop criteria to identify the effects of federal programs on the conversion of farmland to non-agricultural uses. If it is determined that farmland conversion may involve land protected under the FPPA, formal coordination is required per 7 CFR Part 658. The NRCS reviews potential impacts to farmland to determine if the land qualifies as prime or unique farmland or farmland of statewide importance. Forms AD-1006 and CPA-106, which outline direct and indirect impacts to farmland and assign an impact rating at each location, would be submitted by the project for review and scoring by the NRCS. Impacts with scores less than 160 are considered insignificant, between 161 and 200 potentially adverse, and scores over 200 are considered potentially significant. Scores over 160 may require the project to further assess the implications of the proposed action on the farmland and potentially consider alternatives to further minimize or avoid farmland losses. During the environmental review process, agencies having jurisdiction or special use expertise may provide a letter which may include recommended measures to mitigate project effects.

The NRCS has not been requested to complete a Farmland Conversion Impact Rating for any of the South Coast Rail project alternatives at this time because the impacts are not expected to be significant. Drafts of the NRCS Farmland Conversion Impact Rating Forms AD-1006 and CPA-106 have been

prepared for sites larger than 2 acres where designed farmland soils may be impacted. These forms are included in Appendix 4.11-A. Subject to comments from agencies with jurisdiction or special use expertise concerning important farmland, mitigation measures may be developed as appropriate.

Massachusetts Executive Order 193

EO 193 directs state agencies to avoid conversion of agricultural lands to non-agricultural uses. Three criteria are evaluated to determine if a parcel is considered agricultural land for purposes of EO 193:

- the presence of soil types capable of supporting or contributing to present or potential commercial agriculture
- current and historic use for agriculture, and
- absence of non-farm development

Impacts to mapped areas of farmland soils were evaluated where conversion of previously undeveloped land is proposed under each alternative. Although ten sites are located within mapped areas of farmland soils, none are currently in agricultural production. All non-corridor sites are adjacent to existing rail corridors and public roadways and are located in areas that are at least partially developed and are therefore less suitable for conversion to agricultural usage.

Massachusetts Environmental Policy Act/National Environmental Policy Act

MEPA through the Executive Office of EEA requires that state agencies study the environmental consequences of their actions. This mechanism allows the Massachusetts Department of Agricultural Resources to participate in the review of projects that may detrimentally impact state-owned and privately owned agricultural lands. NEPA similarly identifies impacts to farmland soils as requiring investigation during the environmental review process.

Under the MEPA regulatory thresholds published at 301 CMR 11.03(1) (b) (4), the "*conversion of land in active agricultural use to nonagricultural use, provided the land includes soils classified as prime, state-important or unique by the United States Department of Agriculture, unless the Project is accessory to active agricultural use or consists solely of one single family dwelling*" is a threshold that would require that the project undergo MEPA review.[17]

The Secretary's Certificate on the ENF[18] requested review of agricultural lands that may be impacted by the South Coast Rail project. As discussed previously in this chapter, none of the sites that impact farmland soils resulted in a score greater than 160 on Form AD-1006 or CPA-106. These findings indicate that none of the South Coast Rail alternatives would have a detrimental impact on agricultural lands nor would they convert land from active agricultural use to nonagricultural use.

[17] Massachusetts Environmental Policy Act (301 CMR 11.00: MEPA Regulations).
[18] Executive Office of Transportation and Public Works, South Coast Rail Environmental Notification Form, November 2008.

4.12 HAZARDOUS MATERIALS

4.12.1 Introduction

This chapter discusses the potential presence or release of Oil or Hazardous Materials (OHM) in relation to the alternatives under consideration during their construction and operation.

Potential operational impacts of the alternatives may include spills or releases of OHM. However, spills of diesel fuel or hydraulic fluids as a result of a train derailment are not anticipated to occur. Derailments are an extremely rare event, particularly on tracks that are maintained in good condition.

The spill or release of OHM in the process of constructing the alternatives is an unlikely event, and measures would be required to prevent and control any such spills. The construction contractors would implement a Spill Control Program in compliance with the Massachusetts Contingency Plan (310 CMR 40.0000, the MCP) and MBTA policy. These measures would be employed both at the rail reconstruction sites and station construction sites. The following practices would employed on site to prevent, reduce, and clean up spills.

- All spills would be reported to the MBTA and will be reported to appropriate state and/or federal agency if the reportable quantity is exceeded.
- Spill cleanup material would be kept in any chemical storage area.
- All spills would be cleaned up immediately after discovery.
- A spill report would be prepared after each occurrence.
- An appropriately trained employee involved in day-to-day operations would be identified to be the spill prevention coordinator. Each employee would be instructed to report spills to the spill prevention coordinator.
- An inventory of construction and maintenance materials (and corresponding Material Safety Data Sheets) would be maintained as part of the Storm Water Pollution Prevention Plan (SWPPP) for the project.

While the construction activity itself is unlikely to result in the spill or release of OHM, constructing the South Coast Rail alternatives may require acquisition of properties where oil or hazardous materials may already be present in soils or groundwater, or in existing buildings, potentially under conditions that could constitute a prior release pursuant to the MCP. Construction may also encounter contaminated soils or groundwater, or other OHM, within the railroad rights-of-way. The MCP defines the responsibilities of property owners with regard to oil and hazardous material. Several state and federal regulatory programs also govern the requirements for site remediation, transport of regulated hazardous materials, and potential spills during construction.

Rail beds can be contaminated with OHM from a variety of sources, some of which may be exempt from the reporting requirements of the MCP, as stated in the Secretary's Certificate dated April 3, 2009. However, once the materials are excavated or moved, they may be subject to the MCP or other regulations. The Secretary's Certificate recommended that a detailed pre-characterization of soils be

undertaken as recommended by the MassDEP for the station sites and all areas on the right-of-way where construction or rehabilitation is proposed, and to include a draft soil management plan in the EIR.

The Secretary's Certificate on the DEIR, dated July 29, 2011, did not include any new requirements specific to OHM. However, the relocated Stoughton Station and new Dana Street Station site have been evaluated with respect to the potential for OHM-related impacts.

Several locations along the right-of-way and at station locations may contain or have been confirmed to contain subsurface soil and groundwater contamination; underground storage tanks (USTs), and regulated building materials within the buildings to be demolished. Contaminated sites would require the implementation of response actions, as per the MCP, in conjunction with site construction following property acquisition. Response actions would typically consist of the screening and sampling of soil for laboratory analysis of constituents of concern (COCs) and ultimately risk analysis and potentially risk reduction methods such as off-site export of contaminated soil.

After acquisition of a contaminated property, the new owner would be responsible for its cleanup under the MCP. It is therefore advisable that any hazardous waste properties be identified prior to their purchase since the applicant may qualify as an "eligible person" under the Massachusetts Brownfields Act. An "eligible person" is defined under the Act as an owner or operator who did not own or operate the site at the time of the release and who did not cause or contribute to the contamination at the site. If the applicant were determined to be an "eligible person," it could re-establish MCP deadlines for the submittal of response actions and related reports, referred to as Comprehensive Response Actions. The applicant would be required to complete response actions for the property if the release is to soil only. However, the response actions must be completed for the entire site, which may extend beyond the property boundaries, if the release is for impacts to groundwater and/or surface water. Response actions may need to be continued beyond what is required for station construction, as a permanent solution must be achieved for site closure.

The following provides a summary of each of the proposed Alternatives and describes the potential OHM conditions within the locations that may be affected by the South Coast Rail alternatives. OHM in the vicinity of alternatives, including alignment corridors, station locations, and layover facilities are discussed below.

4.12.1.1 Resource Definition

Recognized Environmental Conditions (RECs), as defined by the American Society for Testing and Materials (ASTM) E1527-05 standard practice (Standard Practice for Environmental Site Assessments: Phase I Environmental Site Assessment Process), "means the presence or likely presence of any hazardous substance or petroleum products on a property under conditions that indicate an existing release, a past release, or a material threat of a release of any hazardous substances or petroleum products into structures on the property or into the ground, groundwater, or surface water of the property. The term includes hazardous substances or petroleum products even under conditions in compliance with laws."

In the Commonwealth of Massachusetts, the management of hazardous substance and petroleum products when released into the environment is generally governed by the MCP. Hazardous substances include oil, hazardous material and hazardous waste and are defined as those substances that that may constitute a present or potential threat to human health, safety, welfare, or the environment.

Hazardous materials, as defined in the MCP, include any material in whatever form that, because of its quantity, concentration, chemical, corrosive, flammable, reactive, toxic, infectious or radioactive characteristics, either separately or in combination with any substance or substances, constitutes a present or potential threat to human health, safety, welfare, or to the environment, when improperly stored, treated, transported, disposed of, used, or otherwise managed.

Hazardous wastes are waste materials that, because of their quantity, concentration, or physical, chemical or infectious characteristics, may cause, or significantly contribute to an increase in serious irreversible, or incapacitating reversible illness or pose a substantial present or potential hazard to human health, safety, public welfare or the environment when improperly treated, stored, transported, used or disposed of, or otherwise managed. Oil includes insoluble or partially soluble oils of any kind or origin or in any form, including, without limitation, crude or fuel oils, lube oil, asphalt, insoluble or partially soluble derivatives of mineral, animal or vegetable oils and white oil.

When a hazardous substance impacts (or potentially impacts) an environmental medium, then a release (or threat of release) of OHM is said to occur. As per the MCP, a “release” is defined as “spilling, leaking, pumping, pouring, emitting, emptying, discharging, injecting, escaping, leaching, dumping or disposing into the environment.” A threat of release “means a substantial likelihood of a release of OHM which requires action to prevent or mitigate damage of health, safety, public welfare or the environment which may result from the release.”

As a further refinement of the ASTM E1527-05 definition of RECs, MCP terminology and references are used, since the management of OHM once released in the environment is governed by the MCP.

4.12.1.2 Regulatory Context

Properties with confirmed OHM impacts are generally managed in accordance with the MCP, 310 CMR 40.0000 and associated policies or guidance issued by the DEP. However, depending on the type and concentrations of OHM present at a property, other regulations implemented by the Commonwealth of Massachusetts or the USEPA may apply.

4.12.1.3 Methodology

The Build Alternatives would require construction, including soil removal, within the station, layover facility/right-of-way locations and alternatives. Properties would need to be acquired (in part or in full) for station and layover facility construction. Ballasts, railroad ties, and subsurface soil would need to be removed along existing and out of service railroad tracks. Soil would also need to be removed for the construction of new stations and new rail segments. Several buildings would also need to be demolished.

These activities have the potential to result in the following:

- Encountering contaminated soil or groundwater;
- Disposing of contaminated materials;
- Disposing of solid waste containing lead-based paint, asbestos-containing materials, or other regulated materials such as railroad ties.

- The new owner would become responsible for compliance with the MCP for any property that was acquired for stations, layover facilities, or track construction. Remediation of contaminated "brownfield" sites would be a beneficial effect of the alternatives.

Types of Impacts

Potential impacts at each site were determined based on the type of REC identified through Environmental Site Assessments (ESAs). Since publication of the DEIR/DEIS, the Downtown Taunton Station has been replaced by the Dana Street Station, which is proposed to be located on the east side of the railroad between the alignment and Dana Street. In addition, the Stoughton Station, along with a segment of track leading to the station, would be relocated from the location analyzed in the DEIR/DEIS to the area between Morton Street and Brock Street. Potential contamination associated with property required for the Stoughton Station was identified by a Phase I ESA. Potential contamination associated with the Dana Street Station was identified through an environmental screening, comprised of a literature review of DEP records and a review of historical Sanborn Fire Insurance maps. A detailed description of each REC and potential environmental concern or *de minimis* condition is provided in each of the environmental screenings/ASTM Phase I ESAs prepared for the proposed stations and layover facilities for the alternatives under consideration. Also included in the ESAs, and in the tables provided in the following sections, is the list of state hazardous waste sites and corresponding Release Tracking Numbers (RTNs) on which the RECs are based.

In order to permit a user or purchaser of a property to satisfy one of the requirements to qualify for the "innocent landowner, contiguous property owner, or bona fide prospective purchaser" limitations on the landowner liability protection, it is customary practice to conduct a Phase I ESA on the prospective property. The ESA constitutes "all appropriate inquiry" (AAI) into the previous ownership and uses of the property consistent with good commercial or customary practice. An AAI or ESA is conducted to determine if RECs, defined in Section 4.12.1.1, are likely to be present at the prospective property. Except as identified above, a Phase I ESA was performed for all properties which may be subject to potential acquisition for the South Coast Rail alternatives under consideration, including stations and layover facilities.

ASTM E 1527-05 sets forth a standard practice for determining whether a REC is present. The ASTM Standard Practice includes a review of databases, a site reconnaissance, interviews, and a review of sources such as historic aerial photographs, topographic maps, and Sanborn maps by an Environmental Professional to determine if RECs are present at the property.

Potential impacts were evaluated for each REC identified, based on available information, and classified according to their potential for contamination as either high, medium, or low (discussed below).

Depending on the type of REC, additional investigations may be warranted to assess whether a release has actually occurred. Soils to be excavated may be characterized as part of construction, so as to identify potential COCs that may be encountered. In the event that contamination is identified, response actions would be implemented in accordance with the MCP. The results of an investigation and/or screening could reveal the presence of contaminated media and inform risk assessment.

De Minimis Impacts

The ESA Opinion also includes a section for potential environmental concerns or *de minimis* conditions. Such conditions have less of a potential to impact properties than RECs, and are conditions generally not

subject to extensive regulation. An example of a potential environmental concern or *de minimis* condition would be the potential presence of asbestos-containing materials or lead-based paint, based on the age of the building, which would have to be properly managed during building demolition and would require proper disposal.

Asbestos-containing materials were identified as a potential environmental concern or *de minimis* condition for the majority of the buildings that would need to be demolished to implement the alternatives. Such materials include roof flashing, tiles, and other materials that may be present in the building materials based on the age of the buildings. In addition, lead-based paint, mercury and polychlorinated biphenyls (PCBs) may also be present in the building materials and/or fixtures.

The presence of railroad tracks at or adjacent to proposed stations represents a potential environmental concern or *de minimis* condition common to all stations, as railroad operations can be sources of OHM. Removing ballast, ties or soil along railway corridors would require proper disposal; however, a detailed risk assessment or risk reduction measures may not be required if the material is either statutorily exempt from MGL c. 21E or is consistent with background conditions. The soil exemption may apply only if the soil remains *in situ*. If the material is not exempt from MGL c. 21E and not consistent with background conditions, then appropriate response actions must be performed and a Response Action Outcome (RAO) or Remedy Operation Status (ROS) prepared as a regulatory endpoint.

Beneficial Effects

The alternatives would likely have a positive effect on confirmed areas of soil and groundwater contamination in the proposed station and layover locations. On-site contamination encountered would be assessed and if necessary, remediated prior to and during construction activities as per the MCP. Re-use of as much excavated soil as possible, including impacted soil with concentrations below the applicable MCP standards, is the preferred option and is recommended if a pre-risk assessment screening of the material shows that there are no limitations on risk associated with the current and foreseeable use of the property. Remediation of soil which could not be re-used would most likely consist of soil excavation and off-site disposal.

The following describes the locations where environmental screenings/Phase I ESAs were conducted, the methodology used for these assessments, and the methodology used to evaluate the potential impacts associated with RECs (the potential presence of OHM) at each site.

Environmental Screening/Phase I Environmental Site Assessments Study Area

To assess the potential for encountering OHM during the implementation of the South Coast Rail project, Phase I ESAs or environmental screenings were prepared for station locations and layover facilities associated with the alternatives, including the following.

King’s Highway	North Easton	Taunton Depot
Whale’s Tooth	Easton Village	Dana Street
Freetown	Raynham Park	Wamsutta Layover
Fall River Depot	Taunton	Weaver’s Cove East Layover
Battleship Cove	Stoughton	

Phase I ESAs were performed for properties outside the boundaries of the existing rail alignment that will involve property acquisition or ground disturbance. Phase I ESAs were not performed, however, for most properties within the boundaries of the existing rail alignment. The existing corridors were not evaluated because, due to the nature of land use along rail alignments, it can be assumed that there is the potential for adverse impacts to be present in soils or groundwater in these areas, as railroad operations are common sources of OHM releases, such as semi-volatile organic compounds.

Phase I ESA Methodology

Phase I ESAs were performed as per the ASTM E1527-05 Standard Practice and All Appropriate Inquiries (AAI) pursuant to 40 CFR Part 312. The purpose of the Phase I ESAs is to identify RECs in connection with the properties, to the extent feasible pursuant to the process described in the Standard. The Phase I ESAs were completed using the Standard as guidance. The only major modification to the methodology of the ASTM E1527-05 standard is that a “User” was not identified and therefore not asked to perform tasks to help identify the possibility of RECs in connection with the property. The methodology for the Phase I ESAs included the following:

- A computer database search of federal and state files. The federal databases included the current Comprehensive Environmental Response, Compensation and Liability Information System (CERCLIS), National Priorities List (NPL), Resource Conservation and Recovery Act (RCRA), Storage and Disposal (TSD), RCRA Generators, and Emergency Response Notification System (ERNS) list. The state databases included the state equivalent CERCLIS list, spills, USTs, Solid Waste Landfills (SWL), and public water supply lists.

- A review of available DEP files to provide more information about reported releases of OHM identified through the database search on or adjacent to the site. Where the DEP files provided additional information regarding past ownership; historic site usage; past usage, storage and disposal of OHM on and adjacent to the subject site and other evidence of potential environmental impacts, such information was documented.

- A review of available municipal and historic files to assist in confirming ownership history and past usage. Resources included tax records, aerial photographs, Health Department records, Building Department records, Fire Department records, Conservation Commission records, and Sanborn fire insurance maps. Where available, the site history review also identified reports of historic spills, disposal areas, or other past releases of OHM on or adjacent to the property.

- A review of previous site documents including ESAs, if applicable and/or available for review.

- A visual site reconnaissance to observe the site for overt evidence of a release or threat of release of oil and/or hazardous materials within interior and exterior portions of the entire property. The uses of adjoining properties are also documented.

- Interviews of past and present owners and occupants, and state and/or local government officials, whenever possible, and documenting information regarding the uses and physical characteristics of the property.

The methodology for conducting environmental hazardous materials screenings for the Whittenton Alternative involved a review of the regulatory databases identified above and a review of historical sources in order to identify past land uses.

REC Impact Criteria

The ASTM Standard requires an opinion regarding the potential for each REC to affect a site. The potential impact for each REC identified was classified as high, medium, or low, based on available information. Criteria used to determine the potential impacts are discussed below.

- RECs that are deemed to have a high potential impact consist of sites such as those with confirmed soil, groundwater, and/or indoor air impacts that either were not reported to DEP or were reported to the DEP and have undergone some type of cleanup or remain an active case. Those properties that have undergone a cleanup and have achieved a Permanent Solution, such as a RAO, are still considered high potential impact due to the fact that changing site use or regulations, construction activities, a DEP audit of the RAO, or identification of new environmental conditions (such as indoor air impacts in nearby structures) could trigger the need to conduct additional assessment and/or remediation activities. Other RECs with high potential impacts are those for which UST installation records exist but for which removal documentation is absent, indicating a likelihood that USTs may be present and those where the historic uses of the property indicate that substantial quantities of OHM were used and could constitute a release of OHM.

- Properties with RECs that are deemed to have a medium potential impact consist of properties such as those with potential sources of OHM with limited or inconclusive information. For instance, a single-walled steel UST which has been removed, but limited or no documentation was available to show that proper sampling was conducted at the time of the UST removal to confirm that the UST did not leak, may be deemed a REC of medium potential impact.

- RECs that have low potential to impact a site include off-site properties where releases have occurred but have been mitigated or USTs where proper documentation is available indicating a release has not occurred, as well as for properties that have more recently installed USTs equipped with leak detection, are double walled, and/or contain overfill protection and spill containment.

4.12.2 Existing Conditions

The following describes RECs and potential environmental concerns relative to OHM associated with the alternatives, beginning with the alignments of rail alternatives followed by those stations located in the Southern Triangle (New Bedford Main Line followed by Fall River Secondary), and proceeding with stations and layover facilities located along the alternatives alignments. The conclusions of the Phase I ESA that was previously performed for the Stoughton Alternative right-of-way is provided at the end of this discussion. It should be noted that the presence of railroad tracks at or adjacent to a site is identified as a potential environmental concern common to all stations and corridors, as railroad operations are often sources of OHM.

4.12.2.1 Rail Alignments

Stoughton Alternative

Stoughton Alternative Right-of-Way

As part of a previously prepared Phase I ESA for the Stoughton Alternative, the MBTA examined the right-of-way between Canton Junction and Weir Junction in 1998. Database searches were also evaluated between Canton Junction to Stoughton Station in January 2000.

Based on the conclusions of the 1998 Phase I ESA, the following release sites may impact the Stoughton Alternative right-of-way. These sites include Cohen Property, General Cable Corporation, North Easton Historical Industrial Avenue, and Cyn Environmental. A brief description of each property is included below.

- The Cohen Property, located in Taunton, was listed as a “not proposed CERCLIS” site. This site was comprised of scattered fill consisting of automobile parts, coal slag, scrap metal, and construction debris. Analytical results indicated the presence of six VOCs, PCBs, and inorganic compounds above detectable concentrations in soil. The City of Taunton has developed a reuse program with the EPA to use a portion of the site for Department of Public Works storage. The groundwater flows to the east toward Ingell Street. Groundwater contaminants are consistent with the soil analytical results.

- General Cable Corporation located in Taunton is listed for two spills and releases of No. 4 and No. 2 fuel oil. This site is also listed as the prior location eight USTs, now removed, and as a RCRA Small Quantity Generator.

- North Easton Industrial Avenue is a potential environmental concern due to the historical use of the properties since the early 1900s.

- Cyn Environmental Services, located in Stoughton, is listed as Adequately Regulated outside of the MCP. Cyn is regulated by RCRA guidelines and is a RCRA Small Quantity Generator with several spills listed for petroleum products.

In January 2000, the MBTA performed an additional environmental database search for the Stoughton Alternative from Canton Junction to Stoughton Station. Four potential environmental concerns were identified from the database reports. Additional information was obtained from the DEP for sites which are listed, including the Canton Landfill on Pine Street and three state listed hazardous waste sites. Information from the DEP on the Canton Landfill indicated that groundwater contamination was migrating away from the railroad and does not pose a concern to the right-of-way. The three state-listed hazardous waste sites include a Texaco gasoline station at 731 Washington Street, the Canton Department of Public Works facility, and the Lamb Company at 85 Jackson Street. All three sites were reviewed and determined not to have an environmental impact on the right-of-way due to the distance or remedial actions undertaken at these sites.

Whittenton Alternative

Whittenton Branch

The Whittenton Branch consists of approximately 3.4 linear miles of inactive railroad right-of-way that is 66 feet in width and is located between Whittenton Junction (West Britannia Street in Taunton) and extending northeast toward Raynham Junction (the intersection of Broadway and Center Street in Raynham) (Figure 4.12-1). According to aerial photographs and reports that were reviewed for the Phase I ESA, the site appears to have not been used as a railroad since at least 1950. The last known rail use along the Whittenton Branch was in 1958. The majority of the site is unpaved and unused, with the exception of trespassers. A small section of the right-of-way, located to the south of Whittenton Street, is used as a paved access roadway for the nearby Aggregate Industries facility.

Based on the tasks conducted for the Whittenton Bypass Phase I ESA, four RECs and five potential environmental concerns were identified and are described below.

REC #1–Transformer Oil Releases on Adjoining Property, RTN 4-18532—On July 10, 2004, a sudden release of approximately 590 gallons of transformer oil occurred at the Parkman Construction site (also referred to as Dyecraftsmen, Inc.), located at 437 Whittenton Street. This release site is located adjoining and to the west of the subject site and was assigned RTN 4-18532 by the DEP. The fire department records indicated that oil may have migrated to catch basins and adjacent asphalt surfaces. The DEP records indicated that a Class A-2 RAO was submitted to the DEP on July 15, 2005, indicating that a Permanent Solution was achieved; however, contamination was not reduced to background. The RAO report indicated that historical operations may have led to additional transformer oil releases that should be addressed and managed as separate releases. The potential migration of this transformer oil release, as well as indications of historical transformer releases, constitutes a REC with a medium potential impact.

REC #2–Historic Use of Adjoining Property as Industrial Manufacturing—According to historical reports, the adjoining property located at 437 Whittenton Street was used for industrial processes for over 100 years. The property was initially used in the late 1800s and early 1900s as a cotton mill, which included the treating and dying of materials. As indicated by UST records and historical maps, these industrial processes likely used large quantities of OHM including fuel oil, machining oil, dye, and bleach. Although no historical documented releases (other than REC #1 described above) were identified in connection with this property, given the industrial history and close proximity to the site, the potential presence of OHM is considered to be a REC with a medium potential impact.

REC #3–Indication of Significant Historical Dumping—Significant dumping was observed in the wetland area along Segment 1 of the right-of-way consisting of primarily used tires, but also including an old heating oil tank, an oven, car doors, five gallon buckets, a gas can, and other trash. The dumping was identified as an environmental concern given the type and magnitude of discarded materials, including OHM storage containers and at least 50 tires. This dumping has occurred in a wetland habitat and, therefore, has been identified as a REC with a medium potential impact.

REC #4–Central Oil Company, 728 Broadway, Raynham, RTN 4-16976—A kerosene release was identified at the Central Oil Company, with an address of 728 Broadway, Raynham that was reported to the DEP on April 1, 2002.

RTN 4-16976 was assigned to the release. The current facility status for this site is classified as Tier 1D, where the responsible party fails to provide the required submittal to the DEP by a required deadline. During the site reconnaissance, several large aboveground storage tanks were observed at the Central Oil Company facility, located immediately to the east of the right-of-way. The groundwater directional flow at the facility is not known. These tanks and secondary containment appeared to be in below average condition; however, this was not confirmed, as the Central Oil Company facility was not accessed during this site reconnaissance. Given these observations, the release history, the Tier 1D status and the close proximity to the site, the release and observations associated with the facility have been identified as a REC with a high potential impact.

Potential Environmental Concerns—The Whittenton Branch has five potential environmental concerns, including the following.

- During the site reconnaissance, tires, televisions, piles of fibrous material, and other miscellaneous debris were observed in a wooded area of the site. The source of the material was not determined, although some of the debris was identified as household goods and other material possibly derived from an industry using fibrous materials. The disposal of this material on the site is of potential concern because the nature of the debris is unknown and could potentially contain contaminants that would release to the surrounding environment.

- Three leaking underground storage tank sites located between 2,000 and 3,000 feet to the east of Segments 3 and 4 of the site (see Figure 4.12-1) were identified and are listed below:

    - Pop's Service Station, 212 Broadway, Taunton;

    - Broadway Gulf (Sunoco) Station, 225 Broadway, Taunton;

    - Mystic Gas & Properties, 242 and 252 Broadway, Raynham.

- Local groundwater flow direction is reportedly toward the south; however, there are also indications that a municipal public water supply well field is drawing groundwater towards the west. Each of these three properties has a history of leaking underground storage tanks and related releases of petroleum. Given the proximity to the site and the anticipated groundwater directional flow, these properties are not likely to impact the site but pose a potential environmental concern.

- Historical gravel pits and current observed stump dump operations currently overlap the right-of-way. Piles of wood and loam were observed across several acres of land. No solid waste permit or other listing for this operation was identified during this assessment.

- Miscellaneous debris and an old abandoned truck were observed outside of a horse barn and a cart path connecting the horse barn property to the site, situated along Segment 4 (see Figure 4.12-1). The debris and contents of the horse barn could be a source of OHM.

- A Taunton Municipal Light Plant substation is located adjacent to the site at the southwest portion of Segment 1 (see Figure 4.12-1). There was no indication of spills or releases at the substation and there was no labeling indicating the presence of PCBs on the electrical equipment. However, the operation of this equipment adjacent to the site has the potential to release transformer oil and other OHM onto the site.

A portion of the Whittenton Branch near Prospect Hill Pond is adjacent to a construction and demolition (C&D) debris disposal facility that has encroached onto the railroad right-of-way. A limited review was conducted to evaluate fill material reportedly present on the right-of-way for the presence of OHM. The review is summarized below; a full report is provided in Appendix 4.12-A, with figures showing the area and site features.

New England Recycling, Inc. of Taunton stores the C&D debris at the Raynham Facility, which abuts the railroad right-of-way and has an address of 138 (Rear) Broadway in Raynham. Disposal of C&D debris on the railroad right-of-way is not an authorized use of the land.

The following materials are permitted for storage at the Raynham Facility: post-consumer asphalt shingles (non-asbestos containing materials), pre-sorted asbestos/brick/concrete rubble, wood waste, sand, and gravel. These materials were observed on-site, in addition to minor amounts of debris including buckets, plastic bags, wire, and rebar. The solid waste/debris noted does not appear to constitute a release of OHM to the environment as defined by the Massachusetts Contingency Plan (310 CMR 40.00).

The right-of-way is currently occupied by what appears to be material containing stumps, compost, sand, gravel, boulders, and minor amounts of solid waste and debris. The disposal facility operator has indicated that this material is frequently relocated and new material brought into the site and would be relocated at the request of MassDOT.

4.12.2.2 Stations

Southern Triangle

Battleship Cove Station Site

The Battleship Cove Station site is located on a portion of land east of Water Street and west of Route 138 in Fall River, Massachusetts with an address of 24 Ponta Delgada Boulevard (Figure 4.12-2). According to the property field cards obtained from the Fall River, Massachusetts tax assessor's database, the site consists of a portion of two parcels. The two parcels total 0.779 acre; however, only approximately 0.33 acre comprise the site. The property is currently occupied primarily by the "Portas da Cidade" or "Gates of the City" monument, which includes a fountain, flags, and a grassy area. The majority of the site consists of an asphalt paved driveway, concrete sidewalk, and concrete memorial, which was constructed in 2005. The area surrounding the asphalt driveway consists of landscaped grass.

Based on the tasks conducted for the Battleship Cove Station Phase I ESA, two RECs and no potential environmental concerns were identified. The RECs are described below.

REC #1–Historical Use of the Adjoining Properties—As early as 1888, Sanborn maps indicate that the property adjoining the site to the north at 84 Anawan Street was used as a manufactured gas plant, referred to as the Fall River Gas Works. The Fall River Gas Works at the time housed iron gas holders and a coal house. A Sanborn map from 1905 shows an addition of a crude oil tank and "gasometer" to the gas manufacturing property, as well as the new ownership by Borden & Remington chemical storage of a property immediately to the northeast of the site at 115 Anawan Street. A gas tank on the Borden & Remington property was also constructed and abutted the northwestern corner of the site. The 1933 map showed that up to 15 gas "caustic" materials storage tanks were also present on the Borden &

Remington property at least through 1976. The "empty oil tank" adjoining the northeast corner of the site is currently present at the New England Gas Company property.

According to the computer database report, ten 10,000-gallon USTs were removed from a property located at 115 Anawan Street, which is north of the site. In addition, two USTs (one 5,000-gallon gasoline and one 2,000-gallon diesel) were removed from the New England Gas Company with an address of 84 Anawan Street. It is not known if contamination was encountered at the time of the UST removal. In addition, the general practices at the properties of gas manufacturing and chemical storage could have contributed to environmental impacts at the site.

Land to the west, which is currently owned by Borden & Remington Corporation, has also been used for industrial purposes as early as the mid-1800s. The 1933 Sanborn map indicates that the American Printing Company was located at the property until the Firestone Rubber & Latex Company began its operations in approximately 1970. Numerous storage tanks can be seen on these properties from the Sanborn maps. In addition, the property is currently used by a manufacturer of latex and rubber.

The historical use of the adjoining properties including numerous storage tanks containing OHM is considered a REC with a medium potential impact due to the potential for releases to have occurred over the past 150 years of industrial use and these impacts could potentially migrate and affect the quality of site media.

REC #2–Analytical Results from Previous Environmental Report—A Limited Phase II Environmental site Assessment (Phase II) was completed for the site in November 2001. During Phase II investigation, soil samples submitted for laboratory analysis indicated concentrations of several polynuclear aromatic hydrocarbons (PAHs) and lead above the Reportable Concentrations (RCS-2) representing concentrations that may be indicative of urban fill. Based on the results from the Phase II investigation, the soil could currently contain contamination above the applicable standards. The environmental impacts discovered on the site are considered a REC with a high potential impact.

Fall River Depot Station Site

The Fall River Depot Station site is located southeast of the intersection of Davol and Pearce Streets and consists of numerous parcels with eight addresses totaling approximately 5.3 acres (Figure 4.12-3), which are described as follows.

- 825 Davol Street–This northwestern portion of the site consists of a retail discount flooring warehouse with an associated asphalt driveway and storage trailer. This area also encompasses another small vacant parcel with no address (Parcel 0020) which is owned by the City of Fall River.

- 775 Davol Street–This western central portion of the site contains the remnants (roof, metal side supports, and concrete pad) and associated paved surfaces of a former factory building and is surrounded on all sides with chain-link fencing.

- 61 Pearce Street–This northeastern portion of the site is occupied by a brick warehouse building used by a painting company and an electric and alarm company.

- 390 Davol Street–The eastern central portion of the property along the railroad tracks is elevated and consists primarily of a vacant, gravel and grassy area.

- 753 Davol Street and 175 Bayles Street–The central and eastern portions of the property consist of several buildings, including a brick warehouse, and associated paved parking, that are currently being used by Gemco, an electrical and mechanical contractors business.

- 729 Davol Street–the western central portion of the site consists of a cinder block building, referred to as Jimmy's Tire that is being used as a vehicle repair garage and tire sales facility with associated paved parking.

- 713 Davol Street–the western central portion of the site consists of a multi-family residence in the front near Davol Street and another multi-family residence and associated auto detailing business behind the front residence, referred to as Auto Accent.

- 697 Davol Street–the southernmost portion of the site consists of a restaurant referred to as Davol Street Station Seafood Restaurant & Pub with associated paved parking to the south of the restaurant building. A grassy area is located to the east of the restaurant and parking area along the railroad tracks and slopes upward to the north to a small shack and picket fence.

- Based on the tasks conducted for the Fall River Depot Station Phase I ESA, five RECs and two potential environmental concerns were identified and are described below.

REC #1–Analytical Results from Previous Subsurface Investigations—As part of the Phase II subsurface investigation performed in 2001, a total of 14 hollow-stem auger soil borings were advanced at the site, with eight of the borings being completed as groundwater monitoring wells. Petroleum contamination was encountered in three soil borings at depths ranging from 26 to 34 feet, which is consistent with the groundwater interface. Coal, coal ash, and slag were observed in the fill materials at one soil boring. Asphalt and brick were observed in the fill materials at four of the soil borings. Groundwater samples were also collected from the monitoring wells. Groundwater samples from two wells were observed to have a sheen and distinct petroleum odor.

Analytical results for soil collected from three soil borings showed concentrations in excess of the Reportable Concentration (RCS-1) thresholds, as per the MCP, for volatile petroleum hydrocarbons (VPH). Two samples collected from two soil borings showed concentrations in excess of PAH Reportable Concentrations.

Groundwater samples collected from two on-site monitoring wells showed VPH and extractable petroleum hydrocarbon (EPH) concentrations above the MCP Reportable Concentrations (RCGW-2).

Soil and groundwater concentrations in excess of applicable MCP Reportable Concentrations constituted a potential 120-day release notification obligation to DEP in accordance with the MCP. It appears notification was not performed as the site is not listed on the EDR or DEP databases as having a release. The exceedances of VPH and PAH in soil and VPH and EPH in groundwater above the applicable Reportable Concentrations is considered a REC with a high potential impact.

REC #2–Previous and Current Existence of USTs—A geophysical survey performed on the site in 2001 using ground penetrating radar as part of the Phase II subsurface investigation revealed three potential USTs at the site.

The Fall River Fire Department records show that a 2,000-gallon No. 2 fuel oil UST was previously located at the site at 61 Pearce Street beginning in 1948 until at least 1972. A UST removal permit was not provided; therefore, the UST may still be present at the site. In addition, for the property located at 753 Davol Street, a 1,000-gallon No. 2 fuel oil UST is listed as being present in 1948 and 1976. UST removal permits were provided for two 1,000-gallon No. 2 fuel oil USTs which were removed on March 17, 2009. According to the removal permits, a Licensed Site Professional (LSP) was on the site during the UST removals. Also for the 753 Davol Street property, two 4,000-gallon gasoline USTs were removed on December 2, 1998. It is not indicated on the removal permits if contamination was encountered during the removal; therefore, impacted soil, if encountered during the UST removals, may still be present.

A historic Sanborn map from 1950 showed that a gasoline filling station was located on the northwestern corner of the site that contained two gasoline USTs. According to Building Department records, a gasoline filling station was also constructed at the 753 Davol Street property in 1940. No UST removal permits were provided by the Fall River Fire Department. Therefore, the USTs may still be present at the site which constitutes a REC with a high potential impact.

REC #3–Historic Use of Site Properties—A foundry was located in the northeastern portion of the site beginning in the late 1890s. Two gasoline filling stations were located on the northwestern and center portions of the site in the mid-1900s. The northwestern portion of the site was also was previously used as a junk yard and for the storage of vehicles and industrial equipment. In addition, a steel manufacturing company was located in the center portion of the site from the early 1900s until the 1980s. The center portion of the site also appeared to be used for the layover of trains in the early 1900s. A vehicle repair and maintenance garage was located at 729 Davol Street, in the center of the site, from the early 1900s until the present. The Gemco machine shop and metal fabrication shop are currently located at 753 Davol Street. It is not known how long the shops have been operating at this location; however, the website for the company indicates it was founded in 1966, but did not state if Gemco has been operating a machine shop and metal fabrication shop at this location since that time. The historical use of the site constitutes multiple potential sources of OHM and is considered a REC with a medium potential impact due to the potential for releases to have occurred over the past 150 years of industrial use.

REC #4–Use of Site (729 Davol Street) as Vehicle Repair Garage—According to historic Sanborn fire insurance maps, the property located at 729 Davol Street was historically used as a vehicle repair garage since sometime prior to 1933. Jimmy's Tire Shop, which also performs vehicle maintenance and repair, currently operates at this property. Therefore, this property stores, uses, and/or generates petroleum and other OHM. The OHM would typically include waste oil, fuel oil, alcohol, anti-freeze, and degreasing chemicals which can contain chlorinated solvents. The improper use, storage, and/or generation of these products/wastes may have resulted in a release of OHM and is considered a REC with a medium potential impact.

REC #5–Use of Site (753 Davol Street and 175 Bayles Street) as Machine Shop and Metal Fabrication Shop—During a limited site reconnaissance on June 10, 2009, a sign on the office and warehouse building at 753 Davol Street indicated that the property was operated by "Baldor Industrial Electric Motors" and "Gemco Electrical and Mechanical Contractors." An internet search for "Gemco" at the 753 Davol Street address revealed that Gemco is "a leading electrical and mechanical contractor and employs services which include electrical power and controls, mechanical piping, machine work and rigging." The website stated that "Gemco has an 8,250-square-foot shop area that consists of a machine shop and metal fabrication shop." From an open door, soldering/welding and metal cutting/grinding

were observed to be occurring at the time of the site reconnaissance inside the brick warehouse building located at 753 Davol Street. An outside storage area consisting of various pipes and tubes was also observed near the warehouse building. Machine shops typically store and use various OHM in their processes and metal cutting involves the use of lubricating oils and other OHM. These processes may have resulted in a release of OHM and are considered a REC with a medium potential impact.

Potential Environmental Concerns—The Fall River Depot Station site has two potential environmental concerns.

Abandoned debris on the site, including a 55-gallon drum containing a small quantity of water at 825 Davol Street, broken television/computer monitors along the railroad platform, 40 to 50 containers of paint at 775 Davol Street, a large debris pile between Parcels O-15-0032 and O-155-0018, and an overgrown mound of unknown material, are of potential concern because the nature of the debris is unknown and it could contain contaminants that would release to the surrounding environment.

Given the age of the buildings located at the site, it is possible that hazardous materials, including roof flashing, tiles, and other materials, as well as lead-based paint, may be present in remaining building materials, surrounding debris piles, and soils.

Freetown Station Site

The Freetown Station site is located at 165 South Main Street in the Town of Freetown (Figure 4.12-4). The land consists of 14.2 acres, some of which is covered with buildings or paved surfaces that consist of indoor and outdoor storage facilities. Four rectangular storage buildings, along with a paved outdoor storage area, are located on the northeastern portion of the site. The paved outdoor storage area is used for boats, recreational vehicles, trucks, and storage trailers. A cellular phone signal tower and telecommunications facility are located on the site immediately south of the storage facilities. Approximately six large soil piles were observed on the site further south of the cellular phone signal tower. The western portion of the site is vegetated and unoccupied.

Based on the tasks conducted for the Freetown Station Phase I ESA, no RECs were identified for the site; however, three potential environmental concerns were identified and are described below.

Potential Environmental Concerns—The Freetown Station site has three potential environmental concerns:

- An outdoor storage area containing various boats, trucks, and other vehicles was observed during the site reconnaissance. Although the outdoor area was paved, there did not appear to be any engineered secondary containment to prevent a release of motor oil, gasoline, or antifreeze from migrating to environmental receptors. No staining or other indications of spills or release were observed.

- During the site reconnaissance, two pad-mounted electrical transformers were observed on the site. One of the transformers is located in a fenced-in area with the cellular phone signal tower. The second transformer is located outside the fenced-in area to the east of the cellular phone signal tower. A label indicated that this second transformer was owned by Commonwealth Electric Company. There were no stains or other indications of releases observed at the location of the transformers. It is not known if the transformers contain PCB

dielectric fluid. The transformers have the potential to leak transformer oil directly onto the ground.

- Given the age of the buildings located at the site, it is possible that hazardous materials, including roof flashing, tiles, and other materials, as well as lead-based paint, may be present in remaining building materials, surrounding debris piles, and soils.

King's Highway Station Site

The King's Highway Station site, located at 1024 King's Highway in New Bedford, consists of 13.4 acres (Figure 4.12-5). Active railroad tracks are located east of the property. The site is currently a commercial shopping plaza and historically was an industrial site.

Based on the tasks conducted for the King's Highway Station Phase I ESA, two RECs and three potential environmental concerns were identified and are described below.

REC #1–Historical Use of Site as Industrial Manufacturing—According to historical accounts of City of New Bedford personnel, the site and/or adjoining properties were used for industrial processes, including manufacturing ceramic lighting fixtures. These industrial processes likely used OHM, including machining oils, paints, coatings, and glazing. Based on the age of the industrial development and its past use, the potential presence of OHM is considered to be a REC with a medium potential impact.

REC #2–Gasoline Release at Adjoining Property (494 Church Street), Release Tracking Number (RTN) 4-15181—A gasoline release was identified at an adjoining property to the east at 494 Church Street. Information from a DEP file review indicated a release of approximately 1,000 gallons of gasoline had occurred. The DEP was notified of the release in December 1999. The release was issued RTN 4-15181, and a Class A-2 RAO was filed for the site in June 2004, indicating that a Permanent Solution had been achieved for the site; however, the contamination was not reduced to background. Although the anticipated groundwater flow direction is to the southeast, away from the site, the historic release of gasoline in close proximity indicates the possibility of impacts to the site and therefore is considered to be a REC with a low potential impact.

Potential Environmental Concerns—The King's Highway Station site has three potential environmental concerns including:

During the site reconnaissance, the outdoor storage of waste was identified in the rear of Savers retail store on the southern portion of the plaza. The solid waste in this area was observed to be stored in an uncovered and uncontained manner with generally poor housekeeping. Although OHM was not specifically identified, the general storage of waste materials in this manner indicates a potential for historical impacts related to spills and stormwater runoff of OHM.

During the site reconnaissance, two pad-mounted electrical transformers were observed on the eastern or rear portion of the site. One transformer appeared to be in good condition, while the other appeared to be in below average and was not mounted on an elevated pad. An additional pad-mounted electrical transformer was observed further south behind the plaza. There were no stains or other indications of releases observed at the location of the transformers. It is not known if the transformers contain (PCB dielectric fluid. The transformers have the potential to leak transformer oil directly onto the ground.

Based on the age of the buildings located at the site, asbestos-containing materials, including roof flashing, tiles, and other materials, as well as lead-based paint, may be present.

Whale's Tooth Station Site

The Whale's Tooth Station site is located at 532, 536 and 540 Acushnet Avenue, just east of Route 18 in the City of New Bedford (Figure 4.12-6). The land consists of 1.1 acres of paved surface currently used as a ferry terminal shuttle parking area. The surrounding area consists of commercial and light industrial properties. Active railroad tracks run along the eastern property boundary of the site.

Based on the tasks conducted for the Whale's Tooth Station Phase I ESA, three RECs and no potential environmental concerns were identified and are described below.

REC #1–Confirmed Contamination (RTN 4-118) and Historical Use of the Site as Freight Yard—Previous operations at the Conrail yard located at the site included offloading tank railroad cars containing PCBs. The following contaminants were detected in site soils: PCBs, arsenic, lead, and PAHs. The DEP was notified of the release in January 1987 and RTN 4-118 was assigned. The property was managed as a voluntary Brownfields site. The DEP and EPA concluded that it was technically infeasible to remediate the site. Contamination was limited to the fill portion of the site and was not detected in groundwater. Installation of an engineered barrier and implementation of deed restrictions consisting of Activity and Use Limitations (AULs) were sufficient to achieve a Permanent Solution, as defined by the MCP, at the site. Since contaminated soil was left in place beneath the paved surface, potential impacts related to exposures during future excavation or construction at the site exist. The potential impact of this REC is considered medium because exposure is limited due to the engineered barrier and the AUL.

REC #2–Acushnet Estuary (New Bedford Superfund Site)—The Acushnet Estuary, a water body located east of the site, was placed on the EPA's National Priorities List on September 8, 1983, and is referred to as the New Bedford Superfund site. The site contains PCB contamination that affects ambient air, surface water, groundwater, soil, sediment, and the food chain. Responsible parties have been identified; the contamination is the result of improper historic disposal of waste from two manufacturers which occurred over several decades, ending in the 1970s. The site was also reported to the DEP on January 15, 1987 at which time the release was issued RTN 4-122. The site is currently active. Although adequately regulated under state and federal regulations, the PCB contamination associated with this site has the potential to have impacted the subject site historically or potentially impact it in the future and is considered a REC with a medium potential impact.

REC #3–No. 2 Fuel Oil Release at Adjoining Property (618 Acushnet Avenue, RTN 4-14791)—A No. 2 fuel oil release was identified at the Department of Employment and Training, an adjoining property to the north with an address of 618 Acushnet Avenue. Information from a DEP file review indicated that a release of an unknown quantity of oil was reported on June 14, 1999. Approximately 19.3 tons of petroleum contaminated soil was removed from the site. A Class A-2 RAO was submitted to the DEP stating that a Permanent Solution was achieved; however, contamination was not reduced to background. Although the anticipated groundwater flow direction is cross gradient (to the east), the historic leaking fuel oil at the adjoining property is a potential threat of release to the site and is considered a REC with a low potential impact.

Taunton Depot Station Site

The Taunton Depot Station site is located west of the intersection of County Street and Taunton Depot Drive in Taunton (Figure 4.12-7). The site consists of a portion of three parcels totaling approximately 22 acres. The majority of the site is undeveloped. A sewer pumping system and generator associated with the retail stores to the southeast, surrounded by a chain link fence, extends approximately 200 feet west onto the site. An asphalt paved driveway leads up to this area. A truck and metal storage container are also located in that area. The southern portion of the site consists of a grassy field with little vegetation while the northern half of the site is densely wooded with walking paths. Land adjoining the railroad tracks to the west is wooded and consists primarily of wetland areas and small stream, which is a tributary of the Taunton River.

The Taunton Depot Station Phase I ESA did not identify any RECs. However, lead and arsenic based pesticides, herbicides, and/or synthetic fertilizers may previously have been applied to the Taunton Depot Station site when it was used as an orchard. These contaminants do not readily biodegrade and may be present in site soil at elevated concentrations.

Stoughton Alternative and Whittenton Alternative Station Sites

Easton Village Station

The Easton Village Station site is restricted to a portion of the railroad right-of-way that is owned by the MBTA in Easton, Massachusetts according to the Easton Assessor's Map No. 16U. The site is identified by the Easton tax assessor's database as Map and Parcel No. 20R-45 (Figure 4.12-8). Inactive railroad tracks are located in the center of the right-of-way, while overgrown vegetation occupies the majority of the remaining right-of-way. The site is approximately 50 feet in width and 600 feet in length, totaling approximately 30,000 square feet or 0.7 acres, and is located approximately 400 feet south of Oliver Street, 300 feet north of Main Street, and immediately west of Sullivan Avenue and Mechanic Street.

Based on the tasks conducted for the Easton Village Station Phase I ESA, two RECs and one potential environmental concern were identified and are described below.

REC #1–Fuel Oil Release at Adjoining Property (28 Main Street, RTN 4-19778)—Shovel Shop Square, the commercial buildings located on the site at 28 Main Street, was assigned RTN 4-19778 in May 2006 due to a release of petroleum hydrocarbons associated with former USTs. Elevated concentrations of lead and beryllium were also detected. Site remediation has included soil removal, off-site disposal, and dewatering.

Soil excavation occurred immediately west of the site, just north of Queset Brook. In 2006, a total of 42 soil samples collected from the walls and bottoms of the UST excavation areas showed EPH exceedances in 14 samples above the applicable soil standards. However, soil samples collected closest to the site showed no detections above laboratory reporting limits. Groundwater sampling performed in May and August 2007 found no contaminants in any samples at concentrations above the applicable standards, including the groundwater monitoring well located immediately adjacent to the site. Surface water samples from Queset Brook and Shovel Shop Pond collected in May 2007 showed no compounds were detected above the applicable guidelines or standards.

Although laboratory data for soil samples and groundwater closest to the site indicate no concentrations exceeding laboratory reporting limits for the COCs, the release is considered a REC with a low potential

impact because it abuts the subject site. Possible residual contaminants may still be present, and because groundwater flows from the disposal site toward the proposed Easton Village Station, the contaminants could be present on the site and not identified during assessment activities.

REC #2–Petroleum and Historic Fill Release at Nearby Property (64 Main Street, RTN 4-10839)—The Verizon Central Office Facility located at 64 Main Street, approximately 300 feet west of the site, was assigned RTN 4-10839 in October 1994 due to the presence of EPH compounds in soil. The Class A-2 RAO submitted for the property in December 2001 was reviewed. Remediation was conducted beginning in December 1994 and a total of 42 tons of contaminated soil was removed from the site. EPH compounds and PAHs were detected in soil and groundwater above the applicable standards during subsurface investigations which were conducted in 1995 through 1997 and 2000.

As part of a Phase IV Remedy Implementation Plan that was submitted to DEP in 2001, 27 tons of soil was excavated and 300 pounds of oxygen releasing compounds were injected into the base of the excavation area. Groundwater sampled in September 2001 showed no detections of EPH compounds or PAH target analytes above laboratory method detection limits. The source of the contamination is believed to be from a 1,000-gallon capacity No. 2 fuel oil UST and historic fill material.

The groundwater flow direction is shown to be to the northeast, toward the site. Based on this information, conditions present at this property could impact environmental media at the site and is considered a REC with a low potential impact.

Potential Environmental Concern—Easton Village Station has one potential environmental concern. A utility pole with three pole-mounted transformers was observed on the western boundary of the railroad right-of-way at the southern end of Shovel Shop Square. There were no stains or other indications of releases observed at the location of the transformers. It is not known if the transformers contain PCB dielectric fluid. The transformers have the potential to leak transformer oil directly onto the ground.

North Easton Station Site

The North Easton site is located west of the intersection of Roche Brothers Way and Washington Street/Route 138 in Easton and Stoughton, Massachusetts (Figure 4.12-9). The site consists of a portion of three parcels totaling approximately 5.2 acres. The site is currently void of buildings and primarily overgrown with grass or forest. A small wastewater treatment system and leaching field associated with the commercial development on Roche Brothers Way abuts the southern boundary of the site. The remainder of the southern portion of the site is covered with tall grass and serves as a drainage basin for the commercial property at 31 Roche Brothers Way. J F McNamara & Sons Construction Company currently uses the northern portion of the site to store dumpsters and roll-off containers.

Based on the tasks conducted for the North Easton Phase I ESA, no RECs were identified for the site; however, two potential environmental concerns were identified and are described below.

Potential Environmental Concerns—The North Easton Station site has two potential environmental concerns including:

During a site reconnaissance in 2002, it appeared that the southern portion of the site was used for target practice, based on ammunition shells and miscellaneous scrap metal with bullet holes that were observed scattered throughout that area. Ammunition shells and bullets typically contain high

concentrations of lead; therefore, elevated lead concentrations may be present in surficial soil in the area where target practice occurred. The frequency with which the property was used as target practice could not be determined. This activity would constitute a REC if it were determined that target practice occurred frequently at the property or the property was used as a commercial target shooting facility.

The presence of multiple storage containers on the northern portion of the site is of concern as the containers may be old and painted with lead-based paint. In addition, not every dumpster could be inspected for possible contents and the majority of the containers were rusting and in a state of disrepair.

Raynham Park Station Site

The Raynham Park Station site is located at 1958 Broadway in Raynham. The site parcel consists of a portion of the larger Raynham Dog Track Park and totals approximately 20 acres of land, with more than 80 percent of the property covered with buildings or paved surfaces, including dog kennel buildings, truck storage/maintenance buildings, storage containers, and parking lot space rented for the storage of wooden poles and snow removal equipment (Figure 4.12-10). The inactive rail right-of-way is located west of the property.

Based on the tasks conducted for the Raynham Park Station Phase I ESA, one REC and two potential environmental concerns were identified and are described below.

REC #1–Historic Use of the Site as Truck Maintenance and Industrial Storage—According to observations and reports of operations at the site, trucks, truck parts and equipment, telephone poles, track mats, and other materials have been stored at the site. The property manager for the site stated that the telephone poles are pressure treated and were not treated with creosote. No specific OHM storage was identified at the site during the site reconnaissance. The interiors of the buildings were not accessible during the site reconnaissance and the truck maintenance garage and related OHM storage were not inspected. These site operations could have potentially resulted in a release of OHM to the environment and therefore are considered a REC with a low potential impact.

Potential Environmental Concerns—The Raynham Park Station site has two potential environmental concerns. Two electrical transformers were observed to be located on the site. There were no stains or other indications of releases observed at the locations of the transformers. It is not known if the transformers contain PCB dielectric fluid. The transformers have the potential to leak transformer oil directly onto the ground. Given the age of the buildings located at the site, it is possible that hazardous materials, including roof flashing, tiles, and other materials, as well as lead-based paint, may be present in remaining building materials.

Taunton Station Site

The Taunton Station site is located north of the intersection of Arlington Street and William Hooke Lane in the City of Taunton (Figure 4.12-11). William Hooke Lane (previously referred to as Railroad Avenue) bisects the southern portion of the site in a north-south direction. Arlington Street borders the site to the southwest and the railroad tracks border the site to the east. The site consists of six parcels totaling 10.99 acres.

- Parcel 759–Except for an unoccupied building which is currently located in the southeastern portion of the site (on Parcel 759 with an address of 30 William Hook Lane) and abuts the

railroad tracks, the site does not contain of any building structures. A fire on the Parcel 759 property that occurred in March 2008 burned down the building located on the northern portion of the parcel. The concrete slab foundation and asphalt pavement are still present on the property.

- Parcel 761–This parcel is partially paved. A pile containing miscellaneous trash and debris is located in the southern portion of the parcel. A pile of railroad ties is also located on this parcel.
- Parcels 762, 763, and 764–The northern parcels are unpaved and partially wooded. A small pond and wetland area is located on Parcel 764.
- Parcel 760–Due to a series of fires and consequential demolition which have occurred on (100 Arlington Street) over a period of several years, there are no buildings remaining on the property. Remnants of a building complex, including the concrete slab foundations, are still present. A pond and stream are located in a wooded area on the central portion of the property. The southwestern portion of Parcel 760, which is unpaved, is currently used by contactors as a staging and storage area for the installation of an underground water main in the vicinity of the site. Several trucks, pipes, soil and gravel piles, and equipment are located there.

Based on the tasks conducted for the Taunton Station Phase I ESA, five RECs and four potential environmental concerns were identified and are described below.

REC #1–Historical Use of the Site—

- The Taunton Twist and Drill Company was located at the site west of William Hooke Lane on Parcel 760 beginning in the early 1900s. The New Jersey Rubber Company, a manufacturer of rubber soles and tubing, then occupied the site from the 1920s until the late 1970s. Both of these operations had the potential to release OHM used in manufacturing processes into the environment.
- A coal shed was located east of William Hooke Lane on Parcels 759 and 761 from the late 1800s until the mid-1900s, when Crown Tank Works, a manufacturer of steel tanks, operated on the property until the late 1990s. Coal residues may still be present in the surrounding soil from the loading and unloading of coal into trains.
- Underground fuel storage, manufacturing processes, and OHM storage may have released contaminants into the environment and is deemed a REC with a high potential impact.

REC #2–Conditions Associated with RTN 4-20854 at 100 Arlington Street—A two-hour reporting condition for a spill of five pounds of mercury was reported to the DEP in November 2007 and assigned RTN 4-20854. The release occurred during demolition activities when mercury beads were discovered under a pile of old meters in the bottom of a roll-off container. An Immediate Response Action (IRA) was approved during the initial notification for the excavation of up to 25 cubic yards of soil. No other documents were available for review at the DEP. The presence of OHM and detection of OHM in site media is deemed a REC with a medium potential impact.

REC #3–Conditions Associated with RTN 4-374 and the CERCLIS Listing at 100 Arlington Street—According to a CERCLIS report dated November 1994, improper handling and storage of hazardous substances were the sources of contamination at the property. Toluene was detected at 7,800 parts per million (ppm) and lead was detected at 1,300 ppm in samples collected from drums, bags, and sumps. EPA addressed additional asbestos and oil-contaminated waste debris, as well as transformers located outside the building. A removal action, which included only the wastes that presented an immediate threat to the public, was completed by contractors for EPA in January 1995. The DEP file for RTN 4-374 contained documents relating to the CERCLIS listing. The RTN has been assigned a Tier 1D, which indicates that site is in default because response actions have not been performed by the required deadlines.

The previously hired environmental consultant, who performed the asbestos removal for the 100 Arlington Street property, was interviewed on February 6, 2008. The environmental consultant stated that he reviewed the results of sampling activities previously conducted by EPA and that the soil and sediment collected from the on-site stream showed the presence of PAHs and metals impacts above regulatory criteria. The environmental consultant could not be certain if there were any regulatory exceedances in groundwater. The detection of OHM in site media and the out of compliance status indicating that this release is not being properly addressed are deemed a REC with a high potential impact.

REC #4–Conditions Associated with RTN 4-403 at 30 Railroad Avenue (William Hooke Lane)—According to a Phase I Initial Site Investigation Report prepared in 1995 by Quigley Environmental for Parcel 759, the property at the time consisted of a two-acre tank fabrication facility referred to as Crown Tank Works. Open areas on the property were used for parking and to store metal, liquid products consisting of naphtha and primer that were used for fabricating and finishing tanks. The report stated that an environmental assessment report prepared in 1987 indicated that contaminated soil was encountered during a tank removal operation and gasoline compounds were detected in one water sample. In addition, accidental kerosene spillage was reported by on-site personnel during routine handling practices. A RAM Plan to conduct response actions at the site was also prepared for the site and a RAM Completion Statement was submitted to the DEP in August 1996.

A Class A-3 RAO to permanently close out the site was prepared by Norfolk Environmental and submitted to the DEP in January 2002. A deed restriction, consisting of an AUL, was also implemented for the site.

The presence of multiple OHM sources, detection of OHM in site media, and an AUL is deemed a REC with a high potential impact.

REC #5–Transformer Found at 30 William Hooke Lane (Parcel 759)—During the site reconnaissance visit on November 17, 2008, a fallen pole-mounted transformer on an unpaved surface was observed near the foundations of the demolished building at 30 William Hooke Lane. The transformer was once located on a utility pole that was damaged by fire. The transformer appeared to be an older model, which is typically associated with PCB-containing oils.

The potential presence of an OHM source and detection of OHM in site media is deemed a REC with a medium potential impact.

Potential Environmental Concerns—The Taunton Station site has four potential environmental concerns:

- Given the age of the former buildings which were previously located at the site, it is possible that asbestos-containing materials may be present in the floor tiles currently remaining at the site.

- Given the age of the current building remaining at the site, it is possible that hazardous materials, including roof flashing, tiles, and other materials, as well as lead-based paint, may be present in remaining building materials, surrounding debris piles, and soils.

- Three pole-mounted transformers were observed on a utility pole on the eastern side of William Hooke Lane. There were no stains or other indications of releases observed at the locations of the transformers. It is not known if the transformers contain PCB dielectric fluid. The transformers have the potential to leak transformer oil directly onto the ground.

- A pile containing miscellaneous debris including lumber, old buckets, tires, and plastic tarps was observed in the southern portion of Parcel 761. The asphalt pavement was weathered and cracking. A large pile of railroad ties was also observed in the area along the existing railroad tracks. The parcel was once used to store trucks, and there were also small pieces of automobile parts scattered across the property. The general storage of debris materials in this manner indicates historically poor housekeeping practices and a potential for impacts to environmental media. In addition, railroad ties specifically contain certain OHM.

Dana Street Station

The proposed Dana Street Station site is adjacent to the active Attleboro Secondary rail line and includes on-site and nearby historic and current industrial uses (Figure 4.12-12). A literature review of MassDEP records and Sanborn Fire Insurance maps identified the following environmental concerns for the site; a full report is provided in Appendix 4.12-A, with figures showing the area. The report provides the following observations:

- The proposed station site is partially occupied by an active state-listed disposal site. The disposal site may be out-of-compliance with the applicable regulations and the lack of documentation suggests that remedial actions have not been conducted to mitigate soil contamination that has been identified on site, including petroleum constituents and metals.

- The site and abutting property to the south has a long history of industrial use: the property at 28 Dana Street, for example, is currently used as a scrap yard. The extent to which these industrial activities have impacted the site is unknown.

- A portion of the site west of Dana Street was formerly occupied by a railroad yard since at least 1888. Contaminants associated with former railroad operations include metals and semi-volatile organic compounds. Urban fill, which can contain metals and polycyclic aromatic hydrocarbons, may have also been placed on the site in order to fill in wetland areas. A vegetation control program may have been implemented in the railroad right-of-way and may have introduced lead, arsenic, and other pesticide/herbicide-related contaminants into soils.

The site environmental media have the potential to be impacted by numerous sources related to industrial and, potentially, agricultural uses. Contamination associated with the disposal site has been documented.

Prior to construction, it is recommended that a plan be developed to properly handle and manage soil and groundwater that may be contaminated, which would likely incorporate pre-characterization of media requiring management. Soils should be handled in a manner that protects the health and safety of workers, nearby receptors, and visitors to the site. In addition, impacted soil and groundwater should be managed in accordance with applicable regulations and policies prior to leaving the site, should export be required.

Relocated Stoughton Station

The Stoughton Station is proposed to be located north of Brock Street, south of Morton Street and west of the rail alignment. A Phase I ESA was conducted for the parcels that would be acquired in whole or in part for the station and the realignment of the tracks in the vicinity of the station. The assessment was conducted to identify, to the extent feasible, RECs in connection with the property. The Phase I ESA is attached in Appendix 4.12-B.

Nine properties with RECs were identified during the Phase I ESA. Four of these parcels are property on which the station would be located, while the other five parcels are off-site but nearby. Two of the on-site parcels comprise the main portion of the proposed site and would be acquired in whole. Only small portions of the other two on-site parcels would be needed for the station. Final design of the station may eliminate these two taking requirements, resulting in these RECs being re-categorized as occurring on off-site parcels (Figure 4.12-13).

The Phase I ESA determined that four of the parcels comprising the site (two at 25 Brock Street, and one each at Morton Square and Morton Street) have a moderate potential to contain soil and groundwater contaminants due to prior or current industrial activities. The two properties which may be partially acquired have a high potential of containing petroleum-contaminated soils or groundwater. Reported releases and industrial uses on adjacent properties also constitute a low to moderate potential to affect the site. The nine RECs are discussed below.

REC #1–2 Canton Street, Former Use of Property and On-Site Disposal Site (RTNs 4-21470, 4-875, and 4-18753)—A disposal site located at 2 Canton Street was assigned RTN 4-875 for a release of petroleum discovered during the removal of two underground storage tanks (USTs) in 1989. A second disposal site was assigned RTN 4-21470 for petroleum contamination discovered during the removal of an additional UST. A third disposal site was assigned RTN 4-18753 in October 2004 for the detection of separate phase product in two piezometers. The presence of contamination is associated with the industrial uses of the property, which have included operation by the Mystic Rubber clothing company, Stoughton Rubber Company, and Joseph F. Corcoran Shoe Company. A Class A-3 Response Action Outcome (RAO) was achieved for all three disposal sites in October 2009, which indicates that contaminant concentrations were not reduced to background, and a Condition of No Significant Risk is dependent upon the implementation of an activity and use limitation (AUL) on the property. The former petroleum storage, industrial uses, and existing contamination on the Site are deemed a REC with a high potential impact.

REC #2–Off 17 Morton Square, Murphy Coal Company, On-Site Automotive Repair, Petroleum Storage, and Disposal Site (RTN 4-13478)—An on-site disposal site on the property off Morton Square owned by Murphy Oil Company was assigned RTN 4-13478 in November 1997 when a representative

from MassDEP identified an oil-stained area and improperly stored waste oil at the property. The disposal site achieved a Class A-1 RAO in May 1998, which indicates that a Condition of No Significant Risk was achieved and contaminant levels were reduced to background.

According to Sanborn maps, the property has been occupied by Murphy Coal Company since at least 1923, and formerly contained a coal shed and scales. The company is currently permitted for three 15,000-gallon and two 10,000-gallon above ground storage tanks (ASTs) associated with the sale and distribution of fuel oil. The ASTs have been present since at least 1957 according to historic aerial photographs and the current condition of the tanks is unknown. The assessor's card also indicates that the property is used as an automotive repair garage. Former repair operations at the property may have required the use of OHM including petroleum products, solvents, and other OHM. These OHM have the potential to contaminate environmental media when not handled or disposed of properly. In addition, during the Site reconnaissance, several piles of fill (gravel, sand, stumps), and pieces of heavy machinery were also observed on the property. The origin of the fill material is unknown, and machinery can leak petroleum or fluids to the environment when not properly maintained. These industrial uses of the property and record of environmental contamination are deemed a REC with a medium potential impact.

REC #3–25 Brock Street, Former Use of the Property and On-Site Disposal Site (RTN 4-13476)—The two site parcels with an address of 25 Brock Street have an extensive history of industrial uses, including operation by the Meade Rubber Company in the early 1900s, L. Albert & Son rubber machinery in the mid-1900s, and a latex and shoe materials manufacturer around 1966. According to recent environmental reports, the property has also been used as a machine shop. According to the Fire Department, five petroleum ASTs have been removed from the Site. No information was available regarding the condition of the tanks or analytical testing of the surrounding environmental media. Furthermore, a complaint was filed by the Fire Department in 1979 noting an oil storage violation at the property. According to the assessor's cards, two of the Site buildings are currently heated with oil.

In addition, a disposal site located at 25R Brock Street was assigned RTN 4-13476 in November 1997 for a release of approximately 15 gallons of No. 2 fuel oil. The release occurred when a 275-gallon AST tipped over and began leaking from a pipe. The disposal achieved a Class A-1 Response Action Outcome (RAO) in August 1999, which indicates that contaminant concentrations were reduced to background and a Condition of No Significant Risk was achieved. The industrial uses of the property, former petroleum storage, and presence of an on-Site disposal site are deemed a REC with a medium potential impact.

REC #4–48 Wyman Street, Former Use of the Property as a Machine Shop—The property at 48 Wyman Street comprises a portion of the Site, and was formerly used for the sale of automotive parts, and as a machine shop. Former repair operations at the property may have required the use of OHM including petroleum products, solvents, and other chemicals. These OHM have the potential to contaminate environmental media when not handled or disposed of properly. In addition, the property is noted by the assessor's to be heated with oil and the condition of any storage tanks at the property is unknown. No access was granted in order to observe the interior of the building located on the Site and it has been conservatively assumed that a REC with a low potential impact is present associated with former site use including a machine shop and petroleum storage.

REC #5–931 Washington Street, Current Auto Repair and Former Filling Station (Off-Site)—The property located at 931 Washington Street was formerly the location of a gasoline station as depicted in

the 1966 Sanborn map. An associated 3,000-gallon gasoline UST, which was installed in March 1947, has been removed from the property according to the MassDEP UST Query database. No information was available regarding the condition of the tank or analytical testing of the surrounding environmental media. The property has also been permitted as a Conditionally Exempt Small Quantity Generator (CESQG) since 1986 and is currently used for automotive repair. Manifests have been used to transport ignitable hazardous waste, such as petroleum distillates, from the property since this time. These chemicals have the potential to contaminate environmental media when not handled or disposed of properly. The property is located approximately 50 feet east of the site. The former use of the property as a gasoline station and current use for automotive repair in close proximity to the site are deemed a REC with a medium potential impact.

REC #6–24-46 Morton Street, Chemical Company (RTN 4-11611, Off-Site)—Alpha Chemical Company located at 24-46 Morton Street abuts the Site to the west. The company has been listed as a RCRA CESQG since 2004, and wastes transported from the property under manifest include lead, 1,1,1-trichloroethane, hydrofluoric acid, and dimethyl-benzene. The company manufactures acid sanitizer, disinfectants, mildew preventatives, and liquid chlorinating products. Large aboveground tanks were noted against the western exterior of the company's building during the Site reconnaissance. In addition, a 1,000-gallon fuel oil tank was removed from the property in 1993 and there was no information provided by the Fire Department regarding analytical testing or environmental observations. Chemicals and petroleum stored at the property have the potential to have been released to the environment due to improper handling, disposal, or maintenance of containment structures. The storage of chemicals and petroleum at the property are therefore deemed a REC with a medium potential impact.

REC #7–945 Washington Street, Active Drycleaning Business (Off-Site)—Pearl Drycleaners of 945 Washington Street is listed with the MassDEP as a regulated drycleaning facility. This status indicates that the business utilizes perchloroethylene (PCE), a chemical solvent. When not properly disposed, PCE can contaminate soil and is highly mobile in groundwater. The property is located less than 100 feet southeast of the Site. The chemical handling practices of the drycleaning business are unknown and there is currently no publically available testing data for soil or groundwater between the Site and property. Therefore, the use of chemical solvents at the property is a deemed a REC with a low potential impact.

REC #8–45 Wyman Street, Former Petroleum Storage at Stoughton Train Station (Off-Site)—The historic Stoughton train station constructed in 1888 and located at 45 Wyman Street was formerly heated using three 330-gallon above ground storage tanks located in the building's basement. According to the Stoughton Fire Department, the tanks were removed in 1997; however, no information was provided regarding the condition of the tanks or the surrounding basement floor. There is a potential for petroleum to have been released to the surrounding environment during fuel deliveries, or if the tanks and piping were improperly maintained. The station is located less than 50 feet northeast of the Site. Therefore, the former petroleum storage in close proximity to the Site is deemed a REC with a low potential impact.

REC #9–825 Washington Street, Nearby Disposal Sites and Former Filling Station, (RTNs 4-12937, 4-11868, 4-13560, and 4-13682)—Four releases have been identified at the former gasoline station located at 825 Washington Street. The primary contaminants are petroleum constituents, which are currently undergoing remediation. A definite groundwater flow direction has not been established at this property, which is located approximately 150 feet east of the site. In addition, only one monitoring

well exists between the disposal site and site, which has been frequently dry and therefore may have not been installed at a sufficient depth to detect contamination. Due to this lack of information and the presence of a plume of petroleum constituents in groundwater, the disposal sites at this property are deemed a REC with a medium potential impact.

Additionally, three potential environmental concerns or *de minimis* conditions have been identified for the site:

Based on the age of the on-site buildings that may be demolished for the relocated Stoughton Station, asbestos containing materials, including roof flashing, tiles, and other materials, as well as lead based paint, may be present.

Due to the site's location within a densely developed area, close proximity to a railroad right-of-way and a long history of industrial and commercial use, urban fill may have been used to fill portions of the site. Urban fill can contain metals and polycyclic aromatic hydrocarbons (PAHs) originating from coal/wood ash, tar, and/or slag.

Due to the close proximity of the railroad tracks and likely implementation of a vegetation control program in the vicinity of the railroad tracks, there is a possibility that lead, arsenic, and other contaminants from pesticides are present in site soil.

4.12.2.3 Layover Facility Sites

New Bedford Main Line Layover Site

Wamsutta Layover Site

The Wamsutta layover site is located on a triangular shaped property in a commercial and light industrial area of New Bedford (Figure 4.12-14). The site is located south of Wamsutta Street, east of the railroad tracks, and west of Herman Melville Boulevard and is approximately 12 acres in size. Due to immobile soil contamination, the site was capped with a geotextile membrane in approximately 2004. Two grassy mounds are located on the eastern portion of the site. Railroad tracks abut the site to the west and travel off site to the north. Railroad tracks also extend from the northeastern site boundaries to the harbor, which is located approximately 100 feet to the east. The trains haul dredged sludge from the harbor to the east and travel to the site for off-site disposal.

Based upon the tasks conducted for this Phase I ESA, five RECs and three potential environmental concerns associated with the site were identified and are described below.

REC #1–Historic Use of Site as Freight Yard and Placement of Permanent Engineered Barrier Above Impacted Soil at Site, RTN 4-118—The former Conrail Yard comprising the site was managed as a voluntary Brownfield site. RTN 4-118 was initially assigned to this site and the nearby Whale's Tooth property located south of the site by the DEP in January 1987. The center of the site contained elevated concentrations of PCBs, arsenic, lead, and PAHs with the perimeter having lower concentrations of these contaminants in soil. An agreement was reached with the DEP and EPA based on the financial infeasibility of remediation at the site. The contamination was proposed to be left in place with proper engineering controls, such as a soil geotextile composition cap and land use restrictions consisting of an AUL in the areas exhibiting the highest concentrations of contamination above the Upper Concentration Limits. Since contaminated soil was left in place, there are potential impacts related to exposure during

future soil disturbance at the site during construction related to the South Coast Rail project. Therefore, this condition is considered a REC. The potential impact of this REC is considered medium because exposure is limited due to the engineered barrier and the existence of an AUL.

REC #2–Documented Release at Acushnet Estuary (New Bedford Superfund Site), RTN 4-122—The Acushnet Estuary, a water body located to the east of the site, was placed on the National Priorities List and became a Superfund site in 1983. This site contains PCB contamination that affects ambient air, surface water, groundwater, soils, sediment, and the food chain. The contamination is the result of improper historic disposal of wastes which occurred over several decades up until the 1970s. The site is currently active and was assigned RTN 4-122 by the DEP in 1987. Although adequately regulated under State and Federal regulations, the PCB contamination associated with this site is widespread and has the potential to have impacted the subject site historically or potentially impact it in the future through continued contaminant migration and is considered a REC with a medium potential impact.

REC #3–Documented Fuel Oil Release at Adjoining Property (618 Acushnet Avenue), RTN 4-14791—A No. 2 fuel oil UST release from a western adjoining property, the Department of Employment and Training, located at 618 Acushnet Avenue, was identified in June 1999. A total of 20 tons of petroleum contaminated soil was removed from the property. A Class A-2 RAO, indicating that a Permanent Solution was achieved but that contamination was not reduced to background, was submitted to the DEP. The anticipated direction of groundwater flow is to the east toward the property comprising the site. However, given the quantity and regulatory status, this REC is deemed to have a low potential to affect site media.

REC #4–Documented Diesel Fuel Release and AUL at Nearby Property (1 Wamsutta Street), RTN 4-11715—A diesel fuel UST release from a property located northeast of the site to soil was reported to the DEP in October 1995. Approximately 100 cubic yards of petroleum impacted soil was removed. Exceedances of 2-methylnaphthalene in soil were detected above the applicable regulatory standards and a deed restriction consisting of an AUL was placed on the property along with a Class A-3 RAO in October 1996. Although groundwater was not impacted, the groundwater flow direction was determined to flow to the south-southwest toward the site. Based on the proximity of the site, the direction of groundwater flow, and the implementation of an AUL indicating residual petroleum impacts are present, this REC is deemed to have a low potential to affect site media.

REC #5–Documented PCB Release at Nearby Property (New Bedford Main Interceptor), RTN 4-127—PCBs were detected during the filling of an abandoned interceptor pipe with grout in soil in an area located northeast of the site. Limited documents were available for review on this release at the DEP file review. Available documents stated that an AUL will be necessary to achieve a condition of No Significant Risk for the property indicating residual soil impacts are present. Based on the proximity of this property to the site and the lack of information available for review, this property may have the potential to impact the site and is deemed a REC with low potential to impact the site.

Potential Environmental Concerns—The Wamsutta layover site has three potential environmental concerns:

- An electrical substation containing transformers abuts the site to the west off Acushnet Avenue. It is not known if the transformers contain PCB transformer oil. The transformers have the potential to release transformer oil directly onto the ground surface.

- A motor repair facility abuts the site to the east off Herman Melville Boulevard. Numerous 55-gallon drums were observed outside behind the facility facing the site and most likely contained OHM. The drums were not placed on pallets or any other type of secondary containment structure. Releases or spills from the drums, should they occur, have the potential to impact the site.

- Numerous piles of unused new creosote coated railroad ties were located in two areas in the northern portion of the site. Creosote contains heavy organic compounds that have the potential to leach into soil and groundwater.

Weaver's Cove East Layover Site

The Weaver's Cove East Layover site consists of three parcels and is situated between the railroad tracks, which are located to the west, and North Main Street, which is located to the east, in a mixed use area of Fall River (Figure 4.12-15). The former Shell Oil Company petroleum product distribution facility is located southwest of the railroad tracks. The Weaver's Cove portion of the Taunton River is located immediately west and northwest of the railroad tracks. The parcels comprising the site are currently undeveloped and surrounded by a chain-link fence. Groundwater monitoring wells were observed throughout the site.

The southernmost parcel (Parcel T-1-38) consists of a concrete slab from a former repair garage that was used by the New England Telephone & Telegraph company. The land around the slab consists of grass, shrubs and trees. The center parcel (Parcel T-1-33) consists of a heavily vegetated wetland area that reportedly was formed from a depression caused by the weight of a former gasoline AST. The northernmost parcel (Parcel T-15-1) is vegetated and primarily covered with shrubs and trees.

Based on the tasks conducted for the Weaver's Cove East Layover site Phase I ESA, five RECs and one potential environmental concern were identified and are described below.

REC #1–Previous Use of Site as Oil Storage Facility and Documented Petroleum Release at Site, RTN 4-749—According to historic Sanborn maps, from the early to mid-1900s, a large gasoline AST was located on the center portion of the site. Numerous ASTs of various sizes were also located west of the site across the railroad tracks. The portion of the site that contained the AST was listed as owned by Shell Oil Company (Shell). The AST located at the site was removed in the mid-1900s. According to documents reviewed, Shell operated a crude oil refinery, product storage and distribution facility at the western abutting property from 1920 to 1929 and a petroleum product distribution facility from 1929 to 1995.

Documents obtained from the Fall River Fire Department include a letter from the DEP to Shell Oil Company at One New Street dated February 9, 1993. The letter refers to the Notices of Responsibility dated 1989 and 1992 relative to releases of petroleum products on their property and requests "Short Term Measure Activities" to address the oil release. A map prepared by Handex dated November 4, 1992 depicts a large area of petroleum impacts, which includes the site and the abutting property located west of the site, as well as the former and current tank locations. Contours on the map show the thickness of the LNAPL in groundwater of thickness up to 2.5 feet. In the center of the site, the LNAPL thickness is shown to be 2 feet.

The previous use of the site as an oil storage facility and the documented extensive petroleum release constitutes a REC with a high potential impact.

REC #2–Previous Use of Adjoining Property as Petroleum Product Distribution Facility and Documented Release (Shell Oil Company, 1 New Street), RTN 4-749—As stated in REC #1 above, Shell operated a crude oil refinery, product storage and distribution facility at the western abutting property from 1920 to 1929 and a petroleum product distribution facility from 1929 to 1995. According to documents reviewed, extensive petroleum releases occurred on that property during that time. According to a recent ROS Status Report dated November 2008, this property is currently being remediated with a LNAPL recovery and groundwater treatment system. Even though active remediation activities are currently ongoing and groundwater flows to the northwest toward the Taunton River and away from the site, the presence of extensive LNAPL in the subsurface is deemed a REC with a high potential impact.

REC #3–Previous Use of Building on Parcel T-1-38 as a Commercial Garage—Recent aerial photographs of the southern portion site located on Parcel T-1-38 show the presence of a concrete slab, indicating that a building was once present. A Sanborn map dated 1976 shows the existence of a "private garage" that was operated by New England Telephone and Telegraph Company.

It is assumed that vehicle repairs were performed in this building and that petroleum and other OHM were stored, used, and generated. The petroleum and OHM would typically consist of motor oil, waste oil, fuel oil, alcohol, anti-freeze, and degreasing chemicals that may contain chlorinated solvents. The storage, use, and/or generation of these products may have or could result in a release of OHM constituting a REC with a medium potential impact.

REC #4–Existence of USTs on Parcel T-1-38—According to records received from the Fall River Fire Prevention Department, three USTs were previously located on Parcel T-1-38, which is described above in REC #3, with an address of 2680 North Main Street. The USTs included a 4,000-gallon gasoline tank, a 275 waste oil tank, and a 6,000-gallon No. 6 fuel oil tank. The records document the removal of the gasoline and waste oil tanks which were removed in 1988 and 1987, respectively. There are no records documenting the removal of the No. 6 fuel oil tank.

It was not indicated on the removal records if contamination was encountered during the removal of the gasoline and waste oil tanks and detailed closure reports were not identified. Therefore, OHM may be present in the locations of the former USTs. In addition, it is possible that the No. 6 fuel oil UST, the integrity of which is unknown, may still be present. OHM associated with the USTs formerly/currently on this property would constitute a REC with a medium potential impact.

REC #5–Possible Presence of Elevated Concentrations of Metals in Soil at Adjoining Property (1 New Street)—According to a report reviewed for a western adjoining property, arsenic and beryllium were detected in soil above applicable standards at a depth beginning from the ground surface to a depth of approximately eight feet below grade. The detection of these metals are believed to be attributable to historic filling activities in the 1920s during which fill material was dredged from the Taunton River. According to historic Sanborn maps, the area located to the west of the site was previously under water and was filled in the early 1900s. The Sanborn map also shows a portion of the site to be previously under water; which appears to have been filled in the early 1900s. Therefore, arsenic and beryllium-impacted soil may be present in site soils. Coal ash was found to be present in the fill on the adjacent property; therefore, the presence of metals may be consistent with the MCP's definition of background, and no response actions under the MCP may be necessary. However, aside from the regulatory provisions, the potential presence of OHM at levels which could pose a risk to human or ecological

populations is considered a REC with a low potential impact and would need to be managed appropriately during any proposed construction activities.

Potential Environmental Concern—Weaver's Cove East Layover site has one potential environmental concern. During the site reconnaissance, pole-mounted electrical transformers were observed on the site. It is not known if these transformers contain PCB transformer oil. The transformers have the potential to leak transformer oil directly onto the ground surface.

4.12.2.4 Summary

Phase I ESAs or environmental screenings were conducted for the station sites, layover facility sites and rail corridors associated with the alternatives under consideration. The Phase I ESAs indicate that multiple proposed station and layover locations either border or are the location of known and/or suspected OHM contamination and may also contain building materials that can include asbestos, lead, and other OHM. These conditions represent the potential to encounter OHM impacts when demolishing buildings or constructing new stations and rails, including soil excavation and groundwater management. A table summarizing the RECs and potential environmental concerns for each station site is provided in Table 4.12-1.

Based on the findings of the Phase I ESAs, further evaluation for subsurface contamination may be needed for proposed station, layover, and rail locations with RECs classified as having a high or medium potential to impact each site and which may be subject to disturbance during implementation of the South Coast Rail project prior to acquisition and/or construction. The results of the subsurface investigations previously conducted for Whale's Tooth Station and Wamsutta Layover show that OHM is currently present above regulatory standards below an engineered barrier; these properties, therefore, do not have to be reassessed. Based on updated information regarding Battleship Cove Station and King's Highway Station, no property acquisition or station construction would occur; therefore, no further investigations are recommended for these stations. Further investigation prior to construction is recommended at these sites:

- Stoughton Station
- Fall River Depot
- Raynham Park
- Taunton Depot Station
- Weaver's Cove East
- Dana Street Station
- Whittenton Branch
- Taunton Station
- Freetown Station
- Easton Village

Table 4.12-1 Summary of RECs by Location

Location	REC No.	Ranking	Address	RTN	Impact
King's Highway	1	Medium	Site (1024 King's Hwy)	Not applicable	Historical use
King's Highway	2	Low	Adjoining property (494 Church Street)	4-15181	Gasoline release
Whale's Tooth	1	Medium	Site (532, 536 & 540 Acushnet Avenue)	4-118	Confirmed contamination (PAHs, PCBs, arsenic lead) and capping
Whale's Tooth	2	Medium	Nearby property (Acushnet Estuary)	4-122	PCB release
Whale's Tooth	3	Low	Adjoining property (618 Acushnet Avenue)	4-14791	No. 2 fuel oil release
Fall River Depot*	1	High	Site (390, 775 & 825 Davol St. & 61 Pearce St.)	Not applicable	Confirmed contamination (VPH, EPH, PAHs)
Fall River Depot*	2	High	Site (see above)	Not applicable	Presence of USTs
Fall River Depot*	3	High	Site	Not applicable	Historic use
Fall River Depot*	4	Medium	Site (729 Davol Street)	Not applicable	Historic and current use as vehicle repair garage
Fall River Depot*	5	Medium	Site (753 Davol Street and 175 Bayles Street)	Not applicable	Use as machine shop and metal fabrication shop
Battleship Cove	1	Medium	Adjoining properties	Not applicable	Historic use
Battleship Cove	2	High	Site (24 Ponta Delgata Boulevard)	Not applicable	Confirmed contamination (PAHs and lead)
Easton Village	1	Low	Adjoining property (28 Main St)	4-19778	Fuel oil release
Easton Village	2	Low	Adjoining property (64 Main St)	4-10839	Petroleum and historic fill release
Raynham Park*	1	Low	Site (1958 Broadway)	Not applicable	Historic use
Taunton*	1	High	Site (100 Arlington Street & 30 William Hooke Lane)	Not applicable	Historic use
Taunton*	2	Medium	Site (100 Arlington St.)	4-20854	Mercury release
Taunton*	3	High	Site (100 Arlington St.)	4-374	Metals and petroleum release
Taunton*	4	High	Site (30 William Hooke Lane)	4-403	Gasoline and kerosene release
Taunton*	5	Medium	Site (30 William Hooke Lane)	Not applicable	Possible electrical transformer release

Location	REC No.	Ranking	Address	RTN	Impact
Stoughton Station*	1	High	2 Canton Street	4-875, 4-18753, 4-21470	Former Industrial Property and On-Site Disposal Site
Stoughton Station*	2	Medium	Off 17 Morton Square	4-13478	Murphy Coal Company On-Site Automotive Repair, Petroleum Storage, and Disposal Site
Stoughton Station*	3	Medium	25 Brock Street	4-13476	Industrial and Commercial Use and On-Site Disposal Site
Stoughton Station*	4	Low	48 Wyman Street	Not Applicable	Machine Shop
Stoughton Station	5	Medium	931 Washington Street	Not Applicable	Current Auto Repair and Former Filling Station
Stoughton Station*	6	Medium	24-46 Morton Street	RTN 4-111611	Chemical Company
Stoughton Station	7	Low	945 Washington Street	Not Applicable	Active Drycleaning Business
Stoughton Station	8	Low	45 Wyman Street	Not Applicable	Stoughton Train Station
Stoughton Station*	9	Medium	825 Washington Street	4-12937, 4-11868, 4-13560, 4-13682	Nearby Disposal Sites and Former Filling Station
Dana Street Station*	1	High	140 Dana Street	4-11341	Active State-Listed Disposal Site
Dana Street Station*	2	Medium	28 Dana Street and Site	Not Applicable	Scrap Yard
Dana Street Station*	3	Low	60 Hodges Street	Not Applicable	Pesticides, Herbicides
Dana Street Station*	4	Medium	West of Dana Street	Not Applicable	Former Rail Yard
Wamsutta Layover	1	Medium	Site	4-118	PCBs, arsenic, lead, and PAHs
Wamsutta Layover	2	Medium	Nearby Property (Acushnet Estuary)	4-122	PCB release
Wamsutta Layover	3	Low	Adjoining Property (618 Acushnet Avenue)	4-14791	No. 2 fuel oil from UST
Wamsutta Layover	4	Low	Nearby Property (1 Wamsutta Street)	4-11715	Diesel fuel from UST
Wamsutta Layover	5	Low	Nearby Property (New Bedford Main Interceptor)	4-127	PCBs
Weaver’s Cove East Layover*	1	High	Site	4-749	Previous use as oil storage facility and documented release
Weaver’s Cove	2	High	Adjoining property	4-749	Previous use as

Location	REC No.	Ranking	Address	RTN	Impact
East Layover*			(Shell Oil Co., 1 New Street)		petroleum products distribution facility and documented release
Weaver's Cove East Layover*	3	Medium	Site (Parcel T-1-38)	Not applicable	Previous use as commercial garage
Weaver's Cove East Layover*	4	Medium	Site (Parcel T-1-38)	Not applicable	Existence of USTs
Weaver's Cove East Layover	5	Low	Adjoining Property (1 New Street)	Applicable	Detection of arsenic and beryllium in soil
Whittenton Branch*	1	Medium	Adjoining property (437 Whittenton Ave.)	4-18532	Transformer oil releases
Whittenton Branch*	2	Medium	Adjoining property (437 Whittenton Ave.)	Not applicable	Historic use
Whittenton Branch*	3	Medium	Adjoining property (Segment 1)	Not applicable	Historic dumping in wetland
Whittenton Branch*	4	High	Adjoining property (728 Broadway, Raynham)	4-16976	Kerosene release and use of property

* Further investigation is recommended at these sites

The purpose of the subsurface investigations would be to screen each site for the presence of OHM that could impact construction and/or operation of the stations. In areas determined to be impacted by a release of OHM, soil and groundwater information will be useful in developing a management plan for impacted media and defining worker protection requirements and required response actions (if any) under the MCP.

4.12.3 Analysis of Impacts

4.12.3.1 Southern Triangle (Common to All Rail Alternatives)

Portions of the rail lines within the southern part of the South Coast Rail study area are common to all rail alternatives. These rail lines form a rough triangular shape running south from Myricks Junction to Fall River (the Fall River Secondary) and from Weir Junction through Myricks Junction to New Bedford (the New Bedford Main Line), and are therefore referred to as the Southern Triangle.

The Southern Triangle includes six stations, which include a total of 12 identified RECs. Three of the RECs were evaluated as having a "high" impact, seven RECs were evaluated with "medium" impacts and two RECs were evaluated as having "low" impacts. Table 4.12-2 lists each of the RECs for the stations along the Southern Triangle. Stations located on the Southern Triangle include Battleship Cove, Taunton Depot, Fall River Depot, Freetown, King's Highway and Whale's Tooth. A total of eight structures would be demolished for station construction.

In summary, there is a substantial likelihood that contamination would be encountered and would need to be addressed at Battleship Cove and Fall River Depot stations. There is a moderate likelihood that contamination would be encountered and need to be addressed at King's Highway Station. An engineered barrier was constructed at the Whale's Tooth site and contaminated soil was left in place beneath the barrier. There are potential impacts related to exposure during the future excavation or

construction at this proposed station. It is less likely that contamination would be encountered at the Taunton Depot and Freetown stations.

Table 4.12-2 RECs—Southern Triangle

Station	Number of Structures to be Demolished	REC Description	RTN	Relative Impact
Battleship Cove	0	Analytical Results from Previous Subsurface Investigation	Not applicable	High
		Historical Use of the Adjoining Properties	Not applicable	Medium
Taunton Depot	0	None	Not applicable	Not applicable
Fall River Depot	8	Analytical Results from Previous Subsurface Investigations	Not applicable	High
		Previous and Current Existence of USTs	Not applicable	High
		Historic Use of Site Properties	Not applicable	Medium
		Use of Site (729 Davol Street) as Vehicle Repair Garage	Not applicable	Medium
		Use of Site (753 Davol Street) as Machine Shop and Metal Fabrication Shop	Not applicable	Medium
Freetown	0	None	Not applicable	Not applicable
King's Highway	0	Historic Use of Site as Industrial Manufacturing	Not applicable	Medium
		Gasoline Release at Adjoining Property (494 Church St.)	4-15181	Low
Whale's Tooth	0 (has small attendant's booth and storage shed)	Confirmed Contamination and Historical Use of Property as Freight Yard	4-118	Medium
		Acushnet Estuary (New Bedford Superfund Site)	4-122	Medium
		No. 2 Fuel Oil Release at Adjoining Property (618 Acushnet Avenue)	4-14791	Low

4.12.3.2 Stoughton Alternatives

The Stoughton Alternatives would provide electric or diesel commuter rail service to South Station using the Northeast Corridor, Stoughton Line, New Bedford Main Line, and Fall River Secondary. Both electric (Stoughton Electric) and diesel (Stoughton Diesel) commuter rail options were evaluated for this alternative. The New Bedford route would be 54.9 miles long and the Fall River route would be 52.4 miles long.

This alternative requires improvements to track infrastructure along the Stoughton Line. This alternative also requires reconstructing track on the Southern Triangle, which is common to all rail alternatives, including the New Bedford Main Line and the Fall River Secondary. Infrastructure improvements also include constructing, reconstructing, or widening 43 bridges and constructing or reconstructing 47 railroad at-grade crossings.

This alternative would include eleven new commuter rail stations (Battleship Cove, Taunton Depot, Easton Village, Fall River Depot, Freetown, North Easton, King's Highway, Raynham Park, Stoughton Station, Taunton, Whale's Tooth) and major reconstruction at the existing Canton Center commuter rail stations. This alternative would include two overnight layover facilities, one on the New Bedford Main

Line—the Wamsutta layover facility—and one on the Fall River Secondary—the Weavers Cove East layover facility.

For the electrified option, the traction power system would include two main substations (one in Easton and one in New Bedford), two switching stations (one in Canton and one in Berkley), and six paralleling stations (one in Easton, one in Taunton, two in Freetown, one in New Bedford, and one in Fall River).

Six of the eleven stations are summarized in the Southern Triangle section. For the segment specific to just the Stoughton Alternative, there are five stations, which include Easton Village, North Easton, Raynham Park, Stoughton and Taunton. Table 4.12-3 lists each REC for Easton Village, North Easton, Raynham Park, Stoughton and Taunton. Taking the Southern Triangle into consideration, there are a total of 29 RECs identified. Seven of the RECs were evaluated as having a "high" impact, 15 RECs were evaluated with "medium" impacts and seven RECs were evaluated as having "low" impacts. A total of approximately 25 structures would be demolished for station construction.

In summary, there is a substantial likelihood that contamination would be encountered and would need to be addressed at Taunton Station. It is less likely that contamination would be encountered at Easton Village and Raynham Park stations. It is unlikely that contamination would be encountered at North Easton Station.

4.12.3.3 Whittenton Alternatives

The Whittenton Alternatives would provide electric or diesel commuter rail service to South Station through Stoughton, connecting to the existing Stoughton Line using the Whittenton Branch through the City of Taunton. Both electric (Whittenton Electric) and diesel (Whittenton Diesel) commuter rail options were evaluated for this alternative.

This alternative requires improvements to track infrastructure along the Stoughton Line; Whittenton Line and Attleboro Secondary. This alternative also requires reconstructing track on the Southern Triangle, which is common to all rail alternatives, including the New Bedford Main Line and the Fall River Secondary. Infrastructure improvements also include constructing, reconstructing, or widening 40 bridges and constructing or reconstructing 54 railroad at-grade crossings.

This alternative would include 11 new commuter rail stations (Battleship Cove, Taunton Depot, Easton Village, Fall River Depot, Freetown, King's Highway, North Easton, Raynham Park, Dana Street, Stoughton and Whale's Tooth) and major reconstruction at the existing commuter Canton rail station. This alternative would include two overnight layover facilities, one on the New Bedford Main Line – the Wamsutta layover facility – and one on the Fall River Secondary – the Weavers Cove East layover facility.

For the electrified option, the traction power system would include two main substations (one in Easton and one in New Bedford), two switching stations (one in Canton and one in Berkley), and six paralleling stations (one in Easton, one in Taunton, two in Freetown, one in New Bedford, and one in Fall River).

Six of the eleven stations (Whale's Tooth, King's Highway, Battleship Cove, Fall River Depot, Freetown and Taunton Depot) are summarized in the Southern Triangle section. For the segment north of Taunton Depot there are five stations, including Dana Street (Whittenton Alternative), Taunton (Stoughton Alternative), Raynham Park, Easton village, North Easton and Stoughton. In addition the Whittenton Alternative would include the Whittenton Branch. Table 4.12-4 lists each of the RECs for Easton Village, North Easton, Raynham Park, Dana Street, Stoughton and Whittenton Branch. A total of approximately

25 structures would be demolished for station construction. Taking the Southern Triangle into consideration, there are a total of 24 RECs identified. Seven of the RECs were evaluated as having a “high” impact, 11 RECs were evaluated with “medium” impacts and six RECs were evaluated as having “low” impacts.

Table 4.12-3 RECs—Stoughton Alternatives

Station	Number of Structures to be Demolished	REC Description	RTN	Relative Impact
Easton Village	0	Fuel Oil Release at Adjoining Property (28 Main Street)	4-19778	Low
		Petroleum and Historic Fill Release at Nearby Property (64 Main Street)	4-10839	Low
North Easton	0	None	Not applicable	Not applicable

		Murphy Coal Company On-Site Automotive Repair, Petroleum Storage, and Disposal Site (Off Morton Square) Industrial and Commercial Use and On-Site Disposal Site (25 Brock Street) Former Industrial Property and On-Site Disposal Site (2 Canton Street) Machine Shop (48 Wyman Street)	4-13478 4-13476 4-875, 4-18753, and 4-21470	
		Historic Use: Adjacent Sites	Not Applicable	Medium
		Chemical Company (24-46 Morton Street) Nearby Disposal Sites and Former Filling Station (825 Washington Street) Current Auto Repair and Former Filling Station (931 Washington Street) Active Drycleaning Business (945 Washington Street) Stoughton Train Station (45 Wyman Street)	4-12937, 4-11868, 4-13560, and 4-13682	

4.12.3.4 Layover Facilities

Two layover sites have been identified along the Southern Triangle, including the Weaver's Cove East Layover in Fall River, and the Wamsutta Layover site in New Bedford. For the layover sites, a total of 10 RECs have been identified. Two of the RECs were evaluated as having "high" impacts, four RECs were evaluated with "medium" impacts and four RECs were evaluated as having "low" impacts. Table 4.12-5 lists each of the RECs by layover site. No structures are anticipated to be demolished for the layover sites for station construction.

In summary, there is a substantial likelihood that contamination would be encountered and would need to be addressed Weaver's Cove East layover site. An engineered barrier was constructed at the Wamsutta layover site and contaminated soil was left in place beneath the barrier. There are potential impacts related to exposure during the future excavation or construction at this site.

Table 4.12-5 RECs—Layover Sites

Layover Facility	REC Description	RTN(s)	Relative Impact
Wamsutta	Historic Use of Site as Freight Yard and Placement of Permanent Engineered Barrier Above Impacted Soil at Site	4-118	Medium
	Documented Release at Acushnet Estuary (New Bedford Superfund Site)	4-122	Medium
	Documented Release at Adjoining Property (618 Acushnet Avenue)	4-14791	Low
	Documented Release and Implementation of Activity and Use Limitation at Nearby Property (1 Wamsutta Street)	4-11715	Low
	Documented Release at Nearby Property (New Bedford Main Interceptor)	4-127	Low
Weaver's Cove East	Previous Use of Site as Oil Storage Facility and Documented Petroleum Release on Site	4-749	High
	Previous Use of Adjoining Property as Petroleum Product Distribution Facility and Documented Release (Shell Oil Company, 1 New Street)	4-749	High
	Previous Use of Building on Parcel T-1-38 as Commercial Garage	Not applicable	Medium
	Existence of Underground Storage Tanks (USTs) on Parcel T-1-38	Not applicable	Medium
	Possible Presence of Elevated Concentrations of Metals in Site Soil	Not applicable	Low

4.12.3.5 Summary of Impacts by Alternatives

Each of the alternatives under consideration would require acquisition of properties with RECs that would require further investigation. In each case, remediation or soil/groundwater management during construction could be required. Table 4.12-6 summarizes the number of RECs and the impact that were identified for each alternative.

The Stoughton and Whittenton Alternatives each have at least five high impact RECs that were identified, and these alternatives also have the potential to encounter soil or groundwater contamination. Taunton Station on the Stoughton Alternatives and Dana Street on the Whittenton Alternatives have three and one high impact RECs, respectively that were identified.

Table 4.12-6 Summary of RECs by Alternative*

Alternative	Total Number of Stations	Total Number of RECs	Number of Low Impact RECs	Number of Medium Impact RECs	Number of High Impact RECs
Stoughton Alternatives	11/0	29	5	18	6
Whittenton Alternatives	11/0	32	6	21	5

* Not including Layover facilities

The Stoughton Alternatives and the Whittenton Alternatives would have environmental benefits. Although sites containing RECs could increase construction costs, there would be an environmental benefit associated with remediating contaminated sites, particularly the station sites with known soil and groundwater contamination such as the Taunton Station site. The alternatives that would have the greatest environmental benefits are the alternatives with the most RECs since these properties are the most likely to have contaminated environmental media that would be cleaned up for the proposed South Coast Rail project.

Both layover sites would involve acquisition of properties with RECs that would require further investigation. In each case, remediation or soil/groundwater management during construction could be required. Table 4.12-7 summarizes the number of RECs and the impact that were identified for each layover.

Table 4.12-7 Summary of RECs by Layover Site

Layover	Total Number of RECs	Number of Low Impact RECs	Number of Medium Impact RECs	Number of High Impact RECs
Wamsutta	5	3	2	0
Weaver's Cove East	5	1	2	2

4.12.4 Management of Contaminated Media and Regulatory Compliance

For contaminated property owned by MassDOT, response actions would be required pursuant to the milestones outlined in the MCP. Notification to the DEP would be required if a reporting condition is identified as per the MCP or if OHM is detected in soil and/or groundwater above the applicable standards, referred to as the Reportable Concentrations. An LSP would then most likely need to be retained to verify that notification is required, to further assess and manage the site, direct response actions, and specify procedures for work performed in the contaminated areas, such as soil excavation, in accordance with the MCP and, if need be, to render appropriate Opinions. The LSP would also determine if risk reduction measures are required.

To extend MCP deadlines for response action and report submittals so that the response actions can be coordinated with the construction of the stations, layovers, and expansion of the rail lines, the application for a Special Designation Permit (as per 310 CMR 40.0060 of the MCP) may be warranted.

At many sites containing impacted soil, it is often not possible to reach a regulatory endpoint by using soil excavation and off-site disposal as the only type of remediation. It is advisable to explore other

options such as the re-use of soil in order to minimize the quantity of soil to be excavated and disposed off-site. For low levels of impacted soil where a risk assessment shows an unacceptable risk for current and future unrestricted use, a deed restriction consisting of an AUL may be implemented after construction is completed to meet a regulatory endpoint. As per 310 CMR 40.1012(3) (c) of the MCP, AULs are not required within railroad rights-of-way.

Soil impacted with OHM above the Reportable Concentrations that is encountered during the implementation of the South Coast Rail project would be managed appropriately in accordance with the MBTA Design Construction Standard Specifications, Section 02282, entitled "Handling, Transportation and Disposal of Excavated Material." Preliminary assessment activities may assist in identifying the type and quantity of OHM impacted media which would require management under these protocols and help select the optimal disposal methods and/or destination prior to generation. A summary of the MBTA Specification is provided in the following sections.

4.12.4.1 Management of Impacted Soil

Since contaminated media located on proposed stations and rail rights-of-way may be present from historic releases or urban fill which were not reported to the DEP, a pre-characterization of soils prior to excavation, as recommended by DEP, would be performed. The pre-characterization would consist of a limited subsurface investigation whereby soil samples would be collected, screened, and submitted for laboratory analysis in order to define the nature and extent of contamination in areas where soil disturbance would occur. Based on the pre-characterization described above, a Soil Management Plan would be prepared for the project that is consistent with MBTA specifications.

A Soil Management Plan would be implemented as a waste management tool during soil excavation and removal activities that would occur during construction to ensure soil is property characterized, re-used and/or exported. The primary purpose of the Soil Management Plan is to expedite construction and avoid unexpected costs by minimizing costly off-site disposal and maximizing the re-use of soil within the boundaries of the project.

In order to minimize the need to stockpile and manage the excavated soil, which often can be problematic due to dust, runoff, regulatory time limits on stockpiles, the need for large areas, and impacts to other area, the Soil Management Plan would require the identification of the soil that would be disposed of off-site prior to being excavated, as well as the names of the receiving facilities that would be accepting the soil. It would categorize the soil based on its regulatory status from the specific areas to be excavated. Based on the subsurface investigation analytical results, the soil would fall into four groups, consisting of:

- non-regulated clean;
- soil subject to the anti-degradation policy;
- MCP regulated; and
- RCRA Hazardous Waste.

Re-use and disposal options for each category would then be designated under the Soil Management Plan during construction activities, and soil receiving facilities or destinations would be pre-selected on

either a daily or weekly basis. The soil requiring excavation would be loaded directly into trucks at the site of excavation requiring soil to be removed only once.

Based on the anti-degradation policy and a pre-risk screening which would be performed to determine the risk associated with the current and foreseeable use of the property, the re-use of soil may be possible within the project that is above the MCP standards as long as regulatory endpoints could be met.

Properties with confirmed OHM impacts are generally managed in accordance with the MCP, 310 CMR 40.0000 and associated policies or guidance issued by the DEP. However, depending on the type and concentrations of OHM present at a property, other federal regulations implemented by the U.S. EPA may apply (e.g., Comprehensive Environmental Response, Compensation, and Liability Act of 1980).

Should OHM impacted soil be generated during project-related excavation that requires export or on-site re-use, this material would also need to be properly characterized and managed in accordance with applicable regulations. Proper management would ensure appropriate re-use on the project site to prevent exposure to contaminants or export to appropriate destinations. Characterization may entail the collection of soil samples and analysis for specific parameters specified in the DEP policies for re-use and disposal of contaminated soil. Pre-characterization should eliminate the need to stockpile excess soil onsite pending characterization and if export is needed, generation of the required paperwork. A minimum of ten business days are required for laboratory analysis and approval at a disposal facility or landfill. The stockpiling of soil before characterization on such a large project may lead to delays or outright stoppages of work resulting from management and segregation difficulties and could result in a large volume of soil for which there may not be space to accommodate.

Although re-use should be the preferred option, when characterization of soil after excavation is absolutely necessary, the soil should be segregated into approximately 500-cubic yard sections and placed on and covered with polyethylene sheeting of 10 mil or greater thickness. Covers would be placed on each stockpile at the end of each day’s operations, and would be secured in place to prevent runoff and erosion. A composite soil sample would be collected from each of the 500 cubic yard segments. The soil samples would be submitted for the following, at a minimum, chemical analyses: RCRA 8 metals using Method 6010/7471, VOCs via EPA Method 8260, PCBs via EPA Method 8081, total petroleum hydrocarbons (TPH) via modified EPA Method 8100, SVOCs via EPA Method 8270, reactive cyanide and sulfide using EPA Method SW-846, ignitability using EPA Method 1010, corrosivity using EPA Method 9045, and conductivity using EPA Method 120.1. The specific analyses to be performed will depend upon the requirements of the receiving facility that was selected to accept the soil. Any samples found to contain contaminant concentrations equal to or greater than 20 times their hazardous waste toxicity threshold (*i.e.*, the 20-times rule) would be analyzed for toxicity characteristic leaching procedure (TCLP).

It is assumed that the analysis of pesticides and herbicides would not be required; however, this assumption may be modified based on the requirements of the disposal facility and history of the generator site. Should alternate soil disposal options be pursued (*i.e.*, asphalt batching), analytical requirements may vary depending on the analytical requirements for that facility. Based on the results of the characterization, a Bill of Lading would be prepared to facilitate the export of the soil that would need to be disposed of off-site to the selected disposal facility to ensure that the facility is appropriate to handle the impacted soil. The Bill of Lading would need to be prepared and/or certified by an LSP.

4.12.4.2 Management of Impacted Groundwater

If OHM impacted groundwater is encountered during the implementation of any of the alternatives under consideration, it may also need to be managed in accordance with applicable regulations. If the volume would be limited and subsequent offsite disposal is deemed to be the most cost effective disposal option, the groundwater can be temporarily stored in a 21,000-gallon fractionation tank. It would then be characterized, at a minimum, via laboratory analysis for the following parameters: VOCs via EPA Method 8260, TPH via EPA Method 8100 and SVOCS by EPA Method 8720. For managing larger volumes of groundwater, it may be more cost effective to obtain an EPA Construction General Permit or Remediation General Permit for discharge to surface waters/storm drains or a permit from the local sewer authority, if allowed, for discharge to sanitary sewers.

Contaminated groundwater may also need to be dewatered. However, since dewatering is not cost effective, it is not recommended and therefore should be thoroughly assessed before any decision is made as to remediation. When impacted groundwater has originated from an off-site property, the filing of a Downgradient Property Status may be prudent to suspend response actions and compliance fees. However, response actions may still be necessary in order to achieve a regulatory endpoint beyond those required for project construction.

Large quantities of impacted groundwater encountered by construction activities would also be managed with proper permitting. For smaller quantities, groundwater would be pumped into a containerized 20,000-gallon fractionation tank and removed via a manifest for off-site disposal at an approved facility.

4.12.4.3 Management of Hazardous Demolition Debris and Used Railroad Ties

Asbestos-containing materials, including roof flashing, tiles, and other materials may be present in the building materials for the buildings that would be undergoing demolition, based on their age. In addition, lead-based paint, mercury, and PCBs may also be present in the building materials and/or fixtures. It is recommended that prior to demolition a licensed asbestos and hazardous materials contractor sample the building material, including roof flashing, tiles, and other materials, as well as the potential lead-based paint, mercury, and PCBs. If these hazardous materials are found to be present in the structures, then they must be removed by a licensed contractor in accordance with state regulations.

Re-use of building materials, such as asphalt, brick, and concrete, should be considered, as their re-use could reduce disposal costs and may not require a permit. The re-use would depend on whether they are coated with a contaminant or considered “contaminated” based on the concentrations of contaminants present on the material.

Used wooden railroad ties are typically coated with chemical preservatives including creosote which contains SVOCs and would require special handling procedures. The discarded railroad ties must be managed and disposed of in accordance with applicable regulations.

4.12.4.4 Health and Safety Requirements

In addition, health and safety procedures must be followed under the guidelines of the Occupational Safety and Health Administration. All construction workers involved in performing the response actions must be appropriately health and safety trained in accordance with the Occupational Safety and Health

Act (OSHA) of 1970 (Title 29 United States Code, Chapter 15), which mandates specific procedures that must be followed to be protective from exposure to contaminated media.

4.12.4.5 Closure Reports

At the completion of response actions at properties acquired by the applicant for which an RTN was obtained from the DEP, but a closure report consisting of a RAO has not yet been submitted, a condition of No Significant Risk must exist as defined by the MCP. The preferred outcome is a Class A-1 RAO in which contamination is reduced to background levels. In some situations, the confirmatory sampling results may not support a Class A-1 RAO, and in these situations, alternatives would be evaluated to a Class A-1 RAO. DEP would need to be consulted regarding the planning and implementation of demolition and management of contaminated soil to ensure consistency with the applicable regulations.

Additional response actions beyond those necessary for project construction may be necessary at some of these properties in order to achieve regulatory closure. Such foreseeable response actions could occur pursuant to the MCP as permitted under provisions such as those of a RAM plan, Special Designation Permit, or others, and applicable MCP policies pertaining to construction and waste management.

4.12.5 Temporary Construction-Period Impacts

Mitigation measures during construction may include special handling, dust control, and management and disposal of contaminated soil and groundwater in order to prevent construction delays and to provide adequate protection to workers and any nearby sensitive receptors. All response actions must ensure that any nearby or adjacent receptors are adequately protected.

4.12.5.1 Recommendations

Based on the conclusions of the Phase I ESAs that were performed for the rail alignments, proposed stations, and layovers, the following section describes the recommendations and mitigation measures to be performed prior to and during construction of these stations, track segments, and/or layovers. Recommendations are also discussed below for the Stoughton right-of-way based on an environmental database review that was performed in 2001, since track work and retaining wall construction would be performed along the right-of-way. The recommendations for Phase II ESAs would be to determine existing environmental conditions for property acquisitions and would not consist of soil pre-characterization as part of the Soil Management Plan described above.

Rail Alignments

The track segments where land acquisition or substantial new construction is required include the Whittenton Branch for the Whittenton Alternatives, as well as the Stoughton Line right-of-way for the Stoughton Alternatives. The recommendations for these track segments are described in the following section.

Stoughton Line Right-of-Way (Stoughton and Whittenton Alternatives)

Potential contamination along the Stoughton Line that may require further investigation include the following.

- Cyn Environmental Services located in Stoughton is a state hazardous waste spill site, UST location, and RCRA corrective action site. The site is currently adequately regulated outside of the MCP. Potential soil and groundwater contamination in the right-of-way would be assessed by the applicant prior to construction.

- North Easton Historical Industrial Area is a state hazardous spill site where several USTs have been removed. Unknown material was used for undergrade bridge fill at Main and Bridge Streets. Soil contamination in the right-of-way would be assessed by the applicant prior to construction.

- Petroleum contamination was documented at DeAngelis Iron Works in Easton. The applicant would assess potential soil contamination in the right-of-way prior to construction.

- General Cable Corporation in Taunton is a state hazardous waste spill site and contains a UST. Soil and groundwater contamination is documented. The status and remediation of the UST release and assess oil and groundwater contamination in the right-of-way would be researched by the applicant prior to construction.

The Cohen property in Taunton is a designated Superfund site. Potential soil contamination in the right-of-way would be assessed prior to construction.

Whittenton Branch (Whittenton Alternatives)

A Phase II ESA is recommended for Whittenton Branch in the areas of identified medium impact RECs in which limited soil and groundwater sampling would be performed. Response actions would be implemented as necessary to address any soil or groundwater impacts that may be identified.

Stations

Recommendations for the eleven stations, presented in alphabetical order, are described below.

Battleship Cove Station Site

A Phase II ESA was performed in 2002 for Battleship Cove and identified impacted soil above the regulatory criteria. However, since no property acquisition an updated Phase II ESA is not required.

Dana Street Station Site

Prior to construction, it is recommended that a plan be developed to properly handle and manage soil and groundwater that may be contaminated, which would likely incorporate pre-characterization of media requiring management. Soils should be handled in a manner that protects the health and safety of workers, nearby receptors, and visitors to the site. In addition, impacted soil and groundwater should be managed in accordance with applicable regulations and policies prior to leaving the site, should export be required.

Easton Village Station Site

Because only two low impact RECs were identified on adjoining properties, a Phase II ESA is not recommended. Soils excavated as part of construction should be screened for potential contaminants

that may be encountered. In the event that contamination is identified, response actions would be implemented in accordance with the MCP.

Fall River Depot Station Site

A Phase II ESA was performed in 2002 for the northern portion of the Fall River Depot and identified impacted soil above the regulatory criteria and the potential presence of USTs. An updated Phase II ESA is recommended for the Fall River Depot to obtain updated data from the northern portion of the property as well as to obtain soil and groundwater from the southern portion that was not previously assessed. Response actions may be implemented as necessary to address the impacts that were identified. An update of the 2001 comprehensive survey of the existing buildings will be performed by the applicant for the presence of asbestos-containing materials, lead-based paint, and other regulated building materials.

Freetown Station Site

No RECs were identified at this location; however, soils excavated would be screened as part of construction for potential contaminants that may be encountered. In the event that contamination is identified, response actions would be implemented in accordance with the MCP.

King’s Highway Station Site

Although several RECs were identified at this location, since no property acquisition or station construction is planned, a Phase II ESA is not recommended.

North Easton Station Site

No RECs were identified at this location; however, soils excavated as part of construction would be screened for potential contaminants that may be encountered. In the event that contamination is identified, response actions would be implemented in accordance with the MCP.

Raynham Park Station Site

A Phase II ESA is recommended for Raynham Park in which limited soil and groundwater sampling would be performed. Response actions would be implemented as necessary to address any soil or groundwater impacts that may be identified. A comprehensive survey would be performed of the existing structures for the presence of asbestos-containing materials, lead-based paint, and other regulated building materials.

Stoughton Station Site

Hazardous materials mitigation measures should be incorporated during preliminary and final design of the relocated Stoughton Station. In accordance with DEP requirements, any materials that would be excavated from the project area should be pre-characterized to determine course of action for removal. The specific mitigation measures recommended for oil and hazardous materials are: (1) Prepare a Hazardous Materials and Solid Waste Management Plan, and a Health and Safety Plan, to describe the regulatory context and procedures to be used during construction; (2) Pre-characterize any materials that would be managed during the project to determine the course of action for excavation and disposal. Such pre characterization may include subsurface investigations to determine the nature and extent of any soil or groundwater contamination present; (3) Pre-characterize construction materials in

buildings that would be demolished to identify special or hazardous waste and determine the course of action for removal and disposal; and (4) Pre-characterize any railroad infrastructure that would be removed, such as ties, to determine the course of action for removal and disposal.

Taunton Depot Station Site

No RECs were identified at this location; however, soils excavated as part of construction would be screened for potential contaminants that may be encountered. In the event that contamination is identified, response actions would be implemented in accordance with the MCP.

Whale's Tooth Station Site

An engineered barrier was constructed at Whale's Tooth and contaminated soil was left in place beneath the barrier. There are potential impacts related to exposure during the future excavation or construction at this site. Since known contamination is present at the site but buried beneath an engineered barrier, no soil disturbance or subsurface investigation, including a Phase II ESA, is recommended.

Layover Facility Sites

Wamsutta Layover Facility Site

An engineered barrier was constructed at the Wamsutta Layover site and contaminated soil was left in place beneath the barrier. There are potential impacts related to exposure during the future excavation or construction at this site if soil disturbance below the barrier were to occur. Since known contamination is present at the site but buried beneath an engineered barrier, no soil disturbance or subsurface investigation is recommended, including a Phase II ESA.

Weaver's Cove East Layover Facility Site

A Phase II ESA is recommended for the Weaver's Cove East Layover site, since potentially substantial impacts are likely. The comprehensive surficial and subsurface investigation would address soil and groundwater impacts. Response actions would be implemented as necessary to address environmental media that may be identified.

4.13 GEOLOGY AND SOILS

4.13.1 Introduction

This chapter presents an overview of the physical environment found within the study area of the South Coast Rail alternatives, focusing on physical geography, bedrock and surficial geology, and soils. The chapter evaluates potential impacts of the proposed alternatives to geology and soils, including long-term changes to geologic structures or faults, to bedrock, soils, or geologic stability, to seismicity, or to the rock and soil units surrounding excavations.

4.13.2 Existing Conditions

4.13.2.1 Geology

The South Coast Rail alternatives are situated within the Seaboard Lowland physiographic province of southern New England. The present topography of this region is the result of preglacial, glacial, and postglacial erosion and deposition. During the Wisconsin Period, approximately 17,500 years ago, the advance and retreat of the continental ice mass eroded and picked up bedrock, realigned drainages, and deposited till, erratics, and other glacial material along its course. The slow retreat of the ice sheet, estimated to have been about 2 miles thick at its maximum stage in this region, depressed, shaped, and scoured the landscape, leaving widespread glacial deposits. This resulted in a moderately thick veneer of ice-deposited glacial till, a heterogeneous mix of clay, silt, sand, gravel, and boulders through which bedrock occasionally outcrops. The melting of the Wisconsin ice sheet redeposited meltwater and carried stratified drift throughout the river valleys and lowland areas, which resulted in a variety of small-scale landforms.

Flat-topped terraces of sand and gravel, known as kame terraces, were formed along valley walls by meltwater streams. Sinuous, low ridges of sand and gravel, known as eskers, were deposited by streams running through channels in the ice mass. Stratified deposits of glacial outwash formed broad areas called outwash plains. These plains are typically flat topped, well drained, relatively free of boulders, close to water, and clustered in riverine valley settings. Masses of stagnant ice that had become detached from the glacier were surrounded or partly covered by sand and gravel outwash from the melting glacier. When the detached mass of ice melted, the drift settled and left crater-like pits or kettle holes.

The northern portion of the rail alternatives is situated near the Fowl Meadow section of the Neponset River drainage, which is underlain by sedimentary and igneous rocks belonging to several formations. The primary bedrock units near the project are the Pondville conglomerate and the Wamsutta formation. The Pondville conglomerate consists of cobble and boulder conglomerate and some gray coarse sandstone. The Wamsutta formation is mostly a fine-grained red sandstone with interbedded shale and some gray pebble conglomerate. These sedimentary formations extend in a broad band about 2 miles wide, oriented roughly east/west across the Fowl Meadow area.

The primary bedrock unit of igneous rocks to the north and west of the Fowl Meadow area is the Dedham Granodiorite, a medium- to coarse-grained, light pinkish gray granite rock. Within this formation are small intrusions of the Mattapan Volcanic Complex, which consists of felsite flow, pyroclastic rocks (gray/pink felsite) and small dikes of felsite. To the north of the project area in Canton are the Blue Hills outcrops of volcanic (rhyolite) and contact metamorphic rocks (hornfels) that represent a lithic source area of regional significance in the prehistory of southern New England.

The Whittenton Branch (Whittenton Alternative) is situated in the Narragansett Basin, a structural basin extending from the headwaters of the Taunton River near the Norfolk and Bristol County line south to Narragansett Bay. The Narragansett basin is composed of a sedimentary rock base overlain by glacial deposits. It is one of five Pennsylvania-age basins in eastern Massachusetts, all of which are characterized by generally low-grade metamorphism and by graywacke suites with arkose, plutonic pebbles in the coarser sedimentary rocks, and few orthoquartzites. Volcanic rocks are virtually lacking in this basin with the exception of the Wamsutta Formation. The bedrock geology of the project area is characterized by a substratum of the basin known as the Rhode Island Formation. This formation consists of shale and slate coal-bearing beds intercalated with sandstone and conglomerates.[1]

During the Wisconsin Period, the final glacial episode, the glacier stagnated during its retreat and deposited outwash sands and gravels over the till deposit. Large glacial lakes formed as ice dams trapped glacial meltwaters. The glaciolacustrine and glaciofluvial (types of sediments indicating glacial lakes) deposits formed kame deltas, varved (laminated) clay deposits, and kame terraces, consisting of medium to coarse sand. Glacial Lake Taunton, which covered most of the Taunton River drainage basin also formed.[2] Upon drainage of this lake, large quantities of sediment were transported across the area's low-lying sections and wind redeposited fine sediments to eventually cover topographic features. This wind-blown mantle is as deep as 180 centimeters in some locations.[3] Glacially deposited materials within the project area consist of sediments deposited by glacial outwash, with nearly level (0 to 3 percent) and gently sloping (3 to 8 percent) surfaces.

4.13.2.2 Soils

Soil is produced "through the action of climate, plant and animal life, and humans on parent material in different topographic locations over time".[4] Parent material determines the mineralogical composition and contributes largely to the physical and chemical characteristics of the soil. Glacial ice picked up and ground bedrock, which it then transported and deposited as a jumbled mixture of fresh unweathered rock particles of varying sizes. These sediments were separated and sorted by glacial meltwater and strong winds that distributed fine particles. Vegetation became established, chemical processes of weathering increased, and rock sediments developed into soils. Differences in regional soils are primarily attributed to the interaction of the five factors of soil formation: the parent material, climate, living organisms, relief, and time. The soils in the region have developed over a relatively short span of time, in the approximately 15,000 years since the final retreat of the glaciers. A detailed description of soils and their characteristics is provided in Chapter 4.11, *Farmland Soils*.

Stoughton Alternative

The Stoughton Line (Stoughton Alternative) rail right-of-way and related stations are situated in a wide range of soil classifications, most of which were formed on glacial outwash plains. Major soil types classified along the right-of-way include Windsor, Hinckley, and Agawam series along with Udorthents and Mucks. The range of soil types is variable within specific microenvironments along the project corridor.

Windsor series consists of excessively drained loamy sands on outwash plains. These soils formed in medium and fine sand. Most areas are wooded with white pine and oak. Hinckley series soils formed in

[1] Emerson 1917; Hartshorn 1960, 1976; Zen et al. 1983
[2] Hartshorn 1967:39
[3] Ibid.
[4] USDA 1989:111

thick deposits of water-sorted sand and gravel and occur mainly on terrace escarpments, eskers and kames. Subsoils in this series contain sand, gravel, and cobblestones. These soils are gravelly and low in moisture-holding capacity and are low in organic-matter content. Slope and droughtiness severely limit the use of this soil type for crops or pasture.

Agawam series consists of well-drained, nearly level or gently sloping soils that formed in thick deposits of water-sorted sandy material. These soils are nearly free of gravel to a depth of 1 meter. They occupy plains and terraces along the Taunton River and its tributaries. The Udorthents consist of areas of mineral soils that have been drastically altered by grading and cut-and-fill operations in construction of highways, schools, shopping centers and industrial parks.[5]

Muck consists of very poorly drained soils that formed in an accumulation of organic material decomposed to the extent that the original plant material cannot be readily identified. These soils occupy low areas or depressions that receive surface runoff from nearby higher lying areas. The water table is at or near the surface throughout much of the year.[6]

Whittenton Alternative

The Whittenton Branch (Whittenton Alternative) right-of-way and related station are situated in a wide range of soil classifications. Major soil types classified along the right-of-way include Hinckley, Scarboro, Windsor, and Urban Land series with smaller amounts of Deerfield, Wareham, Pits-Udorthents, and Freetown Muck.[7] The Hinckley and Windsor series are described above. The Scarboro series consists of deep, very poorly drained soils on glacial outwash plains. The soils formed in glacial outwash material derived mainly from granite and gneiss. Urban land consists of areas covered by structures including industrial areas, shopping centers, parking lots and roads.

The Deerfield series consists of deep, moderately well-drained soil on the lower parts of glacial outwash plains. The soils are loamy sand near or adjacent to streams and rivers and formed in glacial outwash derived mainly from granite, gneiss, and quartzite. The Wareham series consists of deep, poorly drained and somewhat poorly drained soils on outwash plains, deltas, and stream terraces. The soils are loamy sand primarily found in depressions and formed in sandy glacial outwash.[8]

The Pits-Udorthents consists of areas that have been excavated for sand and gravel. Depth of excavations ranges from about 5 to 25 feet, and some extend into the water table. Included in this unit are pits that consist of loamy material or that have been used as disposal areas for a wide variety of material. Some areas, especially steep banks, have little or no vegetation while some areas are covered with native species such as bayberry, sweet fern, pitch pine, and gray birch. Freetwon Muck consists of nearly level, deep, very poorly drained soils on uplands and outwash plains. The soils formed in thick deposits of organic material and are located in depressions.

Peat consists of very poorly drained soils that formed in an accumulation of partly decomposed organic material where the plant remains can be readily identified. The Gloucester and Norwell series formed in glacial till derived mainly from granite and gneiss. Gloucester soils are somewhat excessively drained and are very stony loamy sand with surface stones 1 to 3 feet in diameter. Norwell soils are poorly drained extremely stony sandy loam and occupy small, low areas on gently rolling ground moraines.

4.13.3 Analysis of Impacts

4.13.3.1 No-Build (Enhanced Bus) Alternative

The No-Build Alternative (Enhanced Bus) would consist of enhancing current bus service along existing roads and highways. Construction activities would be limited to the modification of three existing Park and Ride facilities, requiring limited clearing and excavate ion No long-term changes would be expected to geologic structures or faults, to bedrock, soils, or geologic stability, to seismicity, or to the rock and soil units surrounding excavations.

Maintenance and development activities within the South Coast Rail project area would be expected to continue, and would create changes in the built environment, but would not adversely impact soils and geologic conditions. Normal geologic processes, such as erosion and sedimentation, would also continue. No specific impacts with respect to soils or geology would be anticipated under the No-Build Alternative.

4.13.3.2 Build Alternatives

As described in detail in Chapter 3, *Alternatives*, the South Coast Rail Build Alternatives would involve subsurface disturbance as a result of the following construction activities:

- Minor repairs or rehabilitation of existing track in active use
- Constructing an additional track on an existing active track segment
- Restoring track and train traffic on out-of-service or abandoned rights-of-way
- Constructing commuter rail stations
- Constructing overhead catenary to allow electrified train service
- Constructing traction power stations
- Construction of layover and maintenance facilities
- Creation of construction staging and laydown areas and construction access roads

Soil and rock affected by the Build Alternatives would be excavated and disturbed during construction. Once a Build Alternative is operational, no further potential long-term impacts to the underlying bedrock geology or soils would be anticipated due to the elements of the Build Alternatives, identified above, including track improvements or construction of new structures such as the trestle in the Hockomock ACEC.

None of the Build Alternatives would require tunneling or other deep excavation that would significantly affect geological conditions. Most disturbance activities would encompass a relatively small area within or adjacent to previously disturbed areas and infrastructure. These include active rail and abandoned rail beds (Stoughton Line and Whittenton Branch) that have previously been established to be compatible with subsurface conditions. No long-term changes would be expected as a result of the Build Alternatives to geologic structures or faults, to bedrock, soils, or geologic stability, to seismicity, or to the rock and soil units surrounding excavations.

No long-term adverse impacts to soils and geology would occur with the Build Alternatives; therefore, no mitigation would be required.

4.14 BIODIVERSITY, WILDLIFE, AND VEGETATION

4.14.1 Introduction

This chapter describes the biological resources and evaluates impacts, both direct and indirect, within and adjacent to the South Coast Rail project corridors in terms of biodiversity, including plant communities, fish and wildlife, and vernal pool habitat for each alternative and its project elements. Threatened and Endangered Species are described in Chapter 4.15. Background information on the proposed project and a summary of each of the alternatives under consideration are provided in Chapter 2 and Chapter 3. Regulatory jurisdiction and compliance with local, state, and federal regulations is discussed as well as measures to minimize, mitigate and compensate for impacts.

This section provides information relative to biodiversity and associated regulations, identifies the Project study area and provides a regional overview of biodiversity including BioMap and Living Water Core Habitats, plant communities, fish and wildlife. Section 4.14.2 describes existing conditions within the study area, relative to biodiversity and Section 4.14.3 describes potential impacts and mitigation measures.

4.14.1.1 Resource Definition

Biological diversity, or “biodiversity,” is an assessment of the numbers, types, and relative abundance of plant and animal species in natural communities. It also describes their relationships to each other and their interactions with the environment. There are three levels of biodiversity; the first is based on the genetic differences among individuals, the second on species richness (i.e. the abundance or rarity of species in a landscape), and the third on the variety of habitats, communities, ecosystems, and landscapes in which those species occur. The concept of biodiversity plays an important role in the connections within and between these levels, and how the interrelated elements sustain the system as a whole. Higher levels of biodiversity are important in maintaining robust ecological communities. This report evaluates the species richness and the variety of habitats, communities, ecosystems, and landscapes in which those species occur within the study area.

All biotic community analyses were conducted in accordance with the requirements of NEPA of 1969;[1] CEQ’s *Incorporating Biodiversity Considerations Into Environmental Impact Analysis Under the National Environmental Policy Act*.[2] In January 1993, the CEQ, in conjunction with the USEPA, prepared a report on biodiversity and how biodiversity conservation can be incorporated into NEPA analyses. CEQ’s *Incorporating Biodiversity Considerations Into Environmental Impact Analysis Under the National Environmental Policy Act* is intended to assist federal agencies in fulfilling their responsibilities under NEPA in the context of biological diversity, by identifying situations where consideration of biodiversity under NEPA is appropriate and to strengthen their effects to do so.[3] For this chapter, biodiversity is described primarily in terms of important wildlife and vegetative resources or “biotic communities” that are known to occur in the South Coast Rail study area. Biotic communities are populations of different organisms including fish, wildlife, and plants that live together in a particular place. Biotic communities are ecological systems in which the natural resources are interdependent. Rare species represent one of

[3] Ibid.

the most sensitive elements of biodiversity and are addressed specifically in Chapter 4.15, *Threatened and Endangered Species*.

4.14.1.2 Regulatory Context

There are currently no applicable federal or state regulations that specifically regulate biodiversity. However, federal and state laws (Endangered Species Act)[4,5] protect rare plants and animals and their critical habitats, and state regulations (Wetland Protection Act)[6] protect the wildlife habitat value of wetlands. Vernal pool habitats are protected under the Massachusetts Water Quality Certification[7] standards as Outstanding Resource Waters. The consequences of the proposed South Coast Rail alternatives are evaluated for comparative purposes under the environmental jurisdiction of MEPA and NEPA. The Secretary's Certificate on the Environmental Notification Form (ENF) identified the need for (1) a baseline ecological assessment and maps and graphics indicating biodiversity values for the project area and (2) a description of the indicators and metrics used to assess biodiversity, including the weighting system used to differentiate among habitat values.

The requirements of the Secretary's Certificate on the DEIR are summarized below:

- The FEIR should include the results of breeding bird surveys and other studies conducted to refine the wildlife impact assessment and mitigation plans. The mitigation plans should include time of year restrictions to protect migratory birds, which are protected under the National Migratory Bird Treaty.

- The FEIR should update the vernal pool inventory and impact assessment for the Stoughton Alternative to clarify vernal pool and vernal pool habitat impacts, as agreed by the Interagency Coordinating Group, and to inform the proposed mitigation plan

- The FEIR should include details on the existing conditions at stream crossings, and explain where culverts will be replaced, extended, or modified. The designs for proposed culverts, bridges, or other alterations at stream crossings should incorporate the Massachusetts River and Stream Crossing Standards.

- The FEIR should evaluate potential direct and indirect hydrological changes, opportunities for maximizing hydrological connections between wetlands for enhancement and restoration as well as for flood capacity, and impacts to fish, amphibians, reptiles, and other wildlife passage.

- The FEIR should include an analysis of spans and open bottom arches to meet Stream Crossing Standards, and consider such arches as mitigation measures throughout the entire rail alignment to the extent they are practicable to improve fish and wildlife passage, and do not interfere with safe train operations.

---

[5] Massachusetts Endangered Species Act of 1990 (MESA [321 CMR 10.00: MGL c. 131A.]), Natural Heritage Endangered Species Program.
[6] Massachusetts Wetlands Protection Act regulations (WPA [310 CMR 10.00 et seq.]).
[7] Massachusetts Water Quality Certification (Section 401 of the Clean Water Act [MGL c. 21 §§ 26 – 53]).

- The FEIR should include mitigation proposals for any unavoidable impacts from bridges and culverts.

- The FEIR should include a summary of the CAPS analysis of ecological integrity impacts associated with the proposed project and the results of additional analysis on the proposed improvements in the Index of Ecological Integrity (IEI) as a result of proposed mitigation measures.

4.14.1.3 State Wildlife Action Plan

The State Wildlife Action Plan (September 2006) is a Comprehensive Wildlife Conservation Strategy (CWCS) developed by the Massachusetts Division of Fisheries and Wildlife (DFW) with the goal of conserving wildlife biodiversity in Massachusetts. The CWCS describes past successful efforts to conserve the biodiversity of the Commonwealth and a review of the landscape changes that have affected wildlife populations. It identifies species and habitats in the greatest need of conservation and lists the primary strategies that DFW plans to use to conserve these species and their habitats through coordination and partnerships with governmental and non-governmental agencies and organizations.

The CWCS identifies seven broad conservation strategies for species and habitats in greatest need of conservation. These include: habitat protection, surveys and inventories of the CWCS species and habitats, conservation planning, environmental regulation, habitat restoration and management, coordination and partnerships, and conservation/environmental education.

The CWCS does not designate specific areas for protection of high diversity. However, it proposes specific conservation actions for each habitat. A summary of common conservation actions among these habitats includes:

- Determining Species Habitat Polygons for each current occurrence of a state-listed animal;

- Locating, mapping, and field-surveying a selected percentage of habitats that are used by rare and uncommon animals;

- Conducting research and surveying for habitats and species of greatest conservation needs that are under-surveyed in Massachusetts;

- Protecting land and areas along waters that support populations of rare and uncommon animals;

- Regulating and limiting the impacts of development on habitats used by state-listed animals;

- Coordinating and working with local agencies and other organizations;

- Identifying and implementing new and old restoration efforts within these habitats and documenting their effects on rare and uncommon species;

- Funding and researching the natural history of animals found within these habitats;

- Informing and educating the public and local decision makers about the value of habitat and species biodiversity and issues related to their conservation; and

- Monitoring and assessing the effectiveness of these conservation actions.

Habitat types found within the study area are discussed below.

4.14.2 Existing Conditions

4.14.2.1 Regional Overview

This chapter includes a general description of the study area and identifies the associated bioregions and major concentrations of Core Habitats along the project corridors.

Study Area

The South Coast Rail study area is considered to be the region of southeastern Massachusetts consisting of southern Bristol and Plymouth Counties, bordering on Buzzards Bay or Mount Hope Bay, including the cities of Fall River and New Bedford and nearby towns. For purposes of this chapter, the study area is the portion of the South Coast region that is adjacent to or crossed by the Build Alternatives. Potential impacts are evaluated in Section 4.14.3 to include all mapped cover types within the proposed limits of work, regardless of the distance from the track center line.

Within the study area, the corridors associated with the alternatives intersect areas that contain wetlands and undeveloped ecosystems that provide higher biodiversity value than other portions of the corridors. Areas of important biodiversity value include wetland areas such as the Hockomock Swamp, Pine Swamp, Assonet Cedar Swamp, Acushnet Cedar Swamp, and Forge Pond, and upland areas such as the Freetown-Fall River State Forest (Figure 4.14-1). Several of these ecosystems are within ACECs, such as the Hockomock Swamp ACEC (Figure 4.14-2). ACECs are described in detail in Chapter 4.10, *Protected Public Open Space and Areas of Critical Environmental Concern*. Relevant Biodiversity features associated with project alternatives are shown on Figures 4.14-3, 4.14-4, 4.14-5, and 4.14-6.

Bioregions

Bioregions are relatively large land areas characterized by broad, landscape-scale descriptions of their natural features and the environmental processes that influence functions of the entire ecosystem.[8] The USEPA defines Bioregions as Ecoregions which are "*areas of general similarity in ecosystems and in the type, quality, and quantity of environmental resources; they are designed to serve as a spatial framework for the research, assessment, management, and monitoring of ecosystems and ecosystem components.*"[9]

Bioregions provide a useful means for simplifying and reporting on more complex patterns of biodiversity, because they include large-scale geophysical patterns in the landscape that are linked to the faunal and floral assemblages and processes at the ecosystem scale. Bioregions vary in size since they can be defined by different criteria, including physical or ecological criteria such as watersheds or associations of biological communities. For example: The USEPA has identified a set of 13 "ecoregions" in Massachusetts based on geology, hydrology, climate, and the distribution of species. The study area is within the ecoregion called "Bristol Lowland/Narragansett Lowland" which is defined as a region that

[8] Department of Environment and Climate Change, New South Whales Government. Website accessed January 2009. (http://www.environment.nsw.gov.au/bioregions/BioregionsExplained.htm).

[9] U.S. Environmental Protection Agency (EPA),Ecoregions of Massachusetts, Connecticut, and Rhode Island. Website accessed January 2009. (http://www.epa.gov/wed/pages/ecoregions/mactri_eco.htm).

has flat, gently rolling plains, the forests are mostly central hardwoods, and there are numerous wetlands, cranberry bogs, and rivers that drain this area.

Most of the study area is within the Taunton River watershed as defined by the Massachusetts Department of Fish and Game Riverways Program.

As defined by the U.S. North American Bird Conservation Initiative (NABCI) Committee, the entire project area is within the New England/Mid-Atlantic Coast Bird Conservation Region (BCR). BCRs are ecologically distinct regions in North America with similar bird communities, habitats, and resource management issues.

Southeastern Massachusetts Bioreserve

Portions of the study area are within the Southeastern Massachusetts Bioreserve. The bioregion concept can be used to guide land management practices adopted in protected areas such as bioreserves. The Southeastern Massachusetts Bioreserve was designated in 2002 and includes approximately 13,600 acres of land just east of Fall River. The Bioreserve is composed of land units owned and managed by separate entities, including the Commonwealth of Massachusetts, the City of Fall River, and The Trustees of Reservations, a nonprofit land conservation organization. The Bioreserve includes 5,150 acres of the Freetown-Fall River State Forest, 360 acres of the Acushnet Wildlife Management Area, 4,300 acres of watershed and conservation lands owned by the City of Fall River, and 3,800 acres of the former Acushnet Saw Mills property that were acquired by the Commonwealth of Massachusetts and The Trustees of Reservations. The purpose of the Bioreserve is "to protect, restore and enhance the biological diversity and ecological integrity of a large scale ecosystem representative of the region; to permanently protect public water supplies and cultural resources; to offer interpretive and educational programs; and to provide opportunities for appropriate public use and enjoyment of this natural environment."[10]

The Bioreserve is managed under a joint management plan that covers several aspects, including forest and wildlife management, water supply protection, and public access. Figure 4.14-1 illustrates the major land units that are part of the Bioreserve.

Important Bird Areas

An Important Bird Area (IBA) is an area that provides important habitat to one or more species of breeding, wintering, and/or migrating birds.[11] These areas are designated as part of an international effort to protect bird habitat around the world. The Massachusetts Audubon Society has designated two Important Bird Areas (IBAs) within the study area: the Hockomock Swamp and the Freetown-Fall River State Forest/Southeastern Massachusetts Bioreserve. Figure 14.14-1 illustrates the major land units that are part of these IBAs. A list of bird species found in the study area and the types of habitat that they require is provided in Table 4.14-1.

[11] Massachusetts Audubon Society, Massachusetts Important Bird Areas. Website accessed January 2009. (http://massaudubon.org/Birds_and_Birding/IBAs/index.php).

Hockomock Swamp IBA

Hockomock Swamp IBA is a 5,126-acre area located in Bridgewater, Easton, Norton, Taunton, West Bridgewater, Bridgewater, and Plymouth. It includes three state-owned wildlife management areas (WMA): the Hockomock Wildlife Management Area, the Wilder Wildlife Management Area, and West Meadows Wildlife Management Area. This IBA provides important migratory/stopover habitat as well as nesting habitat.

The Hockomock Swamp IBA has been reported to contain nine breeding and/or wintering/migrant state-listed species, and at least 47 regional and five state high conservation priority species. Very abundant species are gray catbird (*Dumetella carolinensis*), northern waterthrush (*Seiurus noveboracensis*), common yellowthroat (*Geothlypis trichas*), swamp sparrow (*Melospiza georgiana*), common grackle (*Quiscalus quiscula*), and veeries (*Catharus fuscescens*). State-listed species within this IBA include: grasshopper sparrow (*Ammodramus savannarum*), short-eared owl (*Asio flammeus*), upland sandpiper (*Bartramia longicauda*), common moorhen (*Gallinula chloropus*), king rail (*Rallus elegans*), sharp-shinned hawk (*Accipiter striatus*), northern harrier (*Circus cyaneus*), least bittern (*Ixobrychus exilis*), and pied-billed grebe (*Podilymbus podiceps*).

The major habitat types found within this IBA include oak-conifer forest, cultivated grassland, cultivated field, emergent freshwater wetland, palustrine woodland swamp, shrub-scrub wetland, lake/pond, and river/stream.

Freetown-Fall River State Forest/ Southeastern Massachusetts Bioreserve IBA

The Freetown-Fall River State Forest/Southeastern Massachusetts Bioreserve IBA is a 15,000-acre area located in the towns of Freetown, Fall River, and Bristol. It includes the Freetown-Fall River State Forest, the Acushnet Cedar Swamp, and the Southeastern Massachusetts Bioreserve. This area supports important avian habitat diversity, especially in the Rattlesnake Brook area, and provides important migratory/stopover habitat as well as nesting habitat. Because of the Bioreserve designation, there is a focus on habitat management, research, and monitoring of flora and fauna. Some of the bird monitoring efforts include: Christmas Bird Counts, spring migration bird counts, Breeding Bird Surveys, and Biodiversity Day events. Christmas Bird Counts and Breeding Bird Surveys have been conducted since 1970.

The Freetown-Fall River State Forest/Southeastern Massachusetts Bioreserve IBA has been reported to contain one breeding and/or wintering/migrant state-listed species, and at least seven regional and one state high conservation priority species. Very abundant species include the Eastern towhee (*Pipilo erythophthalmus*), ovenbird (*Seiurus aurocapillus*), and prairie warbler (*Dendroica discolor*). The migrant state-listed species reported to use the site is the Northern parula (*Parula americana)*.

The major habitat types found within this IBA include northern hardwoods forest, oak-conifer forest, pitch pine (*Pinus rigida*)/scrub oak (*Quercus ilicifolia*), early successional shrubland, power line, shrub-scrub wetland, and river/stream.

BioMap Core Habitats

The Natural Heritage and Endangered Species Program (NHESP) published the BioMap Report in 2001. While the report and mapping was updated as BioMap 2 in 2010,[12] the analysis for the DEIS had already been completed and is based on the data provided in the original edition. This study was undertaken to identify critical land in Massachusetts needed to preserve biodiversity in the Commonwealth and is based, in part, on rare species and locations of exemplary natural community in the state. The BioMap Report identified Core Habitats as areas representing "the rare and exemplary habitat of Massachusetts" and Supporting Natural Landscapes as "buffer areas around Core Habitat." The BioMap (BM) Core Habitats encompass nearly 1.4 million acres of uplands and wetlands in Massachusetts. Areas of BioMap Core Habitat that have been mapped within the study area include parts of the Southeastern Massachusetts Bioreserve, Freetown-Fall River State Forest, Acushnet Cedar Swamp, Assonet Cedar Swamp, Hockomock Swamp, and Pine Swamp. Threatened and endangered species are described in detail in Chapter 4.15. The major concentrations of BioMap Core Habitat in the study area are shown on Figures 4.14-1 and 4.14-2 and include:

- Acushnet Cedar Swamp, the Freetown-Fall River State Forest, and the Assonet Cedar Swamp (BM1229) are located in New Bedford, Freetown, and Lakeville (Figures 4.14-3a-e and 4.14-4a and b). This BioMap core habitat contains extensive, minimally fragmented and diverse natural communities that range from forested swamp and bogs (large coastal and alluvial Atlantic white cedar (*Chamaecyparis thyoides*) swamps), to a dry upland pitch pine scrub oak community. This large Core Habitat is an important site that supports several species of rare plants, rare turtles and salamanders, as well as rare moths, butterflies, dragonflies, and damselflies.

- Forge Pond and Assonet River (BM1232) in Freetown provide habitat for the attenuated bluet damselfly (*Enallagma daeckii*) (Figure 4.14-4a).

- Hockomock Swamp (BM1166 and BM1168) is located within the Hockomock Swamp ACEC in Raynham, Easton, Bridgewater, and West Bridgewater and contains the largest unfragmented and pristine areas of wetland habitat in eastern Massachusetts (Figures 4.14-5c-d).[13] These Core Habitats include the highest quality acidic graminoid fen and the largest coastal Atlantic cedar swamp in Massachusetts and a very large red maple (*Acer rubrum*) swamp community. This assemblage provides habitat for several rare insects, rare salamanders and turtles, as well as rare plant species.

- Pine Swamp (BM1196) in Raynham includes an unfragmented Atlantic white cedar swamp that provides habitat for the rare Hessel's hairstreak butterfly (*Callophrys hesseli*) (Figure 4.14-5d).

Living Waters Core Habitats

In 2003, NHESP completed the Living Waters project. Living Waters are critical sites (Core Habitats) of freshwater biodiversity identified within rivers, streams, lakes, and ponds in Massachusetts. Designated

[13] Hockomock Swamp ACEC website: (http://www.mass.gov/dcr/stewardship/acec/acecs/l-hcksmp.htm).

Living Waters in the study area are shown on Figures 4.14-3d, 4.14-4a-b, and 4.14-5e. The major Living Waters found within the study area include:

- Acushnet Cedar Swamp and Turner Pond (LW239) in New Bedford provide habitat for the rare coastal swamp amphipod (*Synurella chamberlain)* and the rare American clam shrimp (*Limnadia lenticularis*) (Figure 4.14-3d).

- Sections of Rattlesnake Brook (LW321) and the Assonet River (LW330) in Freetown provide habitat for several anadromous fishes including blueback herring (*Alosa aestivalis*), rainbow smelt (*Osmerus mordax*), and white perch (*Morone americana*) (Figures 4.14-4a-b).

- Taunton River (LW080) in Taunton provides habitat for the state-listed endangered Atlantic sturgeon (*Acipenser oxyrinchus*), which was listed as an endangered species at the federal level by the National Marine Fisheries Service in 2012 (Figures 4.14-3a and 4.14-5e).

Plant Communities

This section describes the plant communities within the study area grouped into wetland cover types and upland cover types. These community types are based on the NHESP's "*Classification of Natural Communities*" but include some refinements of these types to reflect local conditions.[14] The cover type data was produced based on interpretation of GIS aerial mapping, as well as land use data and wetlands cover type data available from MassGIS.

Wetland Cover Types

Wetland cover types include red maple swamp, Atlantic white cedar swamp, mixed forested wetland, shrub swamp, marshes and fens, and open water. Wetland resources in the study area are described in Chapter 4.16, *Wetlands*.

Red Maple Swamp (RM)

The red maple swamp community is the most abundant community within the study area, as it is throughout southeastern Massachusetts wetlands. The community type includes a red maple overstory, with understory vegetation consisting of highbush blueberry (*Vaccinium corymbosum*), sweet pepperbush (*Clethra alnifolia*), swamp azalea (*Rhododendron viscosum*), common winterberry (*Ilex verticillata*), skunk cabbage (*Symplocarpus foetidus*), cinnamon fern (*Osmunda cinnamomea*), and sensitive fern (*Onoclea sensibilis*). In the Cowardin classification system, these areas are characterized as Palustrine Forested Wetland (PFO), with the ecological subcategory of Wooded Swamp Deciduous (WSD).

Inland Atlantic White Cedar Swamp (AWC)

The Atlantic white cedar swamp is listed by NHESP as a Priority Natural Community. This community type includes Atlantic white cedar in association with red maple, fetterbush (*Leucothoe racemosa*), common winterberry, swamp azalea, cinnamon fern, and royal fern (*Osmunda regalis*). This community also occurs within the Pine Swamp. The Hockomock Swamp and Assonet Cedar Swamp AWC

[14] Natural Heritage Endangered Species Program, Classification of Natural Communities. Website accessed February 2009: (http://www.mass.gov/dfwele/dfw/nhesp/nhclass.htm).

communities consist generally of small to medium sized trees with some larger trees in Assonet Cedar Swamp as well. The size classes of trees indicate that cedar lumber was harvested in these areas during the 18th and 19th centuries, as occurred in most New England AWCs. In the Cowardin classification system, these areas are characterized as Palustrine Forested Wetland (PFO), with the ecological subcategory of Wooded Swamp Coniferous (WSC).

Mixed Forested Wetland (RM/AWC)

The mixed forested wetland community (RM/AWC) is associated with transition areas between Atlantic white cedar swamps and red maple swamps, and transition areas between wetland and upland communities. This community consists of a mixture of deciduous and evergreen overstory trees, and understory shrubs. Dominant plants may include red maple, Atlantic white cedar, highbush blueberry, fetterbush, common winterberry, swamp azalea, sphagnum moss (*Sphagnum* spp.), and cinnamon fern. In the Cowardin classification system, these areas are characterized as Palustrine Forested Wetland (PFO), with the ecological subcategory of Wooded Swamp Mixed (WSM).

Shrub Swamp (SS)

Shrub swamp communities are transition zones between the open water and marshes of the river and the surrounding forested wetlands and uplands. The shrub swamp community includes speckled alder (*Alnus incana*), pussy willow (*Salix discolor*), red-osier dogwood (*Cornus amomum)*, buttonbush (*Cephalanthus occidentalis*), arrow-wood (*Viburnum dentatum*), sensitive fern, and skunk cabbage. In the Cowardin classification system, these areas are characterized as Palustrine Shrub Scrub (PSS) Wetlands.

Marshes and Fens (M)

Marshes are characterized by shallow, standing water throughout the year and have limited shrub and tree cover. Vegetation is generally dominated by herbaceous species such as reeds, sedges, rushes, and grasses. Acid fen plant communities are listed by NHESP as a Priority Natural Community. This community includes sphagnum mosses and sedges with a limited shrub cover of leatherleaf (*Chamaedaphne calyculata*), bog rosemary (*Andromeda glaucophylla*), and Labrador tea (*Ledum groenlandicum*). In the Cowardin classification system, these areas are characterized as Palustrine Emergent Marsh (PEM) Wetlands.

Open Water (W)

This community includes the estuary of Taunton River and Mount Hope Bay as well as a range of fisheries and wildlife habitat such as rivers, ponds, coldwater and warmwater brooks and streams. Coastal plain ponds occupy depressions in glacial outwash plains that are directly linked to the underground aquifer. The coastal plain pondshore community occurs in those ponds with no surface inlet or outlet, and with a gradual slope to the shore. In the Cowardin classification system, these areas are characterized as Open Water (POW) Wetlands.

Permanent ponds and waterways within the study area include Black Brook, Snake River, Assonet River, Taunton River, Neponset River, Three Mile River, Forge Pond, and Turner Pond. Shallow and slow moving portions of this community may be vegetated by aquatic plant species such as fragrant water lily (*Nymphaea odorata*). Areas of open water with deeper and faster flowing waters are generally unvegetated.

Upland Cover Types

Upland cover types include deciduous forest, coniferous forest, mixed forest, agricultural use, developed land, powerline easements, and cleared areas.

Deciduous Forested Upland (UD)

Vegetation within this mixed oak community includes northern red oak (*Quercus rubra*), red maple, gray birch (*Betula populifiolia*), mountain laurel (*Kalmia latifolia*), teaberry (*Gaultheria procumbens*), nannyberry (*Viburnum lentago*), and wild lily-of-the-valley (*Maianthemum canadense*).

Coniferous Forested Upland (UC)

Vegetation within this successional white pine forest community includes eastern white pine, eastern hemlock, mountain laurel, and poison ivy (*Toxicodendron radicans*).

Mixed Forested Upland (C/D)

The mixed forested upland oak-hemlock-white pine community is found within the Freetown-Fall River State Forest and it is the second largest community type within the Hockomock Swamp. This forested community consists of northern red oak, red maple, gray birch, white pine, eastern hemlock (*Tsuga canadensis*), mountain laurel, teaberry, nannyberry, and wild lily-of-the-valley.

Agricultural Use (AG)

Agricultural areas include land in active agricultural use that support cultivated crops or cranberry bogs.

Powerline (P)

Powerline easements occupy wide strips of maintained land that crosses portions of the study area. Both uplands and wetlands occur within this area along maintained access roads. Vegetation growing under the powerlines is maintained by seasonal cutting and herbicide application as part of a vegetation management plan. Due to the artificial nature of its boundaries, this community type includes a variety of both wetlands and uplands with a corresponding diversity of soil types.

Cleared Area (CL)

The cleared areas are generally located along the powerlines. They consist of excavated gravel pits and are largely unvegetated due to clearing activities. This is considered to be a habitat type because some wildlife species may use these cleared areas as suitable habitat for breeding, nesting, and migration.

Wildlife

The study area includes wildlife habitat areas for a diversity of species. These areas include several large wetland complexes and protected upland habitat. These areas possess characteristics that are necessary for maintaining and expanding wildlife populations, particularly area-sensitive species. The wildlife value of these areas is increased by the adjacent undeveloped uplands, which provide habitat for upland species along with breeding and overwintering habitat for wetland-dependent wildlife.

This section provides an overview of the range of wildlife species likely to exist within the study area. The analysis of vertebrate species is based, in part, on wildlife habitat analysis performed using the

NEWILD computer model for the 2002 Final EIR (Stoughton Alternative). The NEWILD computer model was developed by the U.S. Department of Agriculture, Northeastern Research Station as part of the NED project, a program to develop software tools to support ecosystem management decision making.[15] Other literature used to determine occurrences are referenced at the end of each vertebrate list.

Birds

Table 4.14-1 lists bird species that may potentially occur within the Hockomock Swamp and other important habitat areas along the project corridors. The list includes species that may breed in the study area, as well as species that may stop over on migratory flights or overwinter. The table also indicates whether species are area-sensitive (require large areas of unfragmented forest), require forest interior or edge habitats, and the types of vegetation that the species utilizes. Some of the species found in the study area are opportunists that can be found in a variety of habitat types, while some species are more specialized and occur in a narrower range of habitat types.

Table 4.14-1 Potential Bird Species Found Within the Study Area

Habitat Use: I = Interior (nest only within forest interiors, rarely near forest edge); I/E = Interior/Edge – territories located entirely within the forest but can only use edges; E = Edge – species use forest perimeters, nearby fields or large clearings during breeding season.

Source: Freemark, K. and B. Collins. 1992. Landscape ecology of birds breeding in temperate forest fragments. Pages 443-454 in *Ecology and conservation of neotropical migrant landbirds*, J.M. Hagan III and D.W. Johnston, eds. Smithsonian Institution Press, Washington, DC.

Shading indicates forest-interior breeding bird species

As described in the section on Important Bird Areas, the Massachusetts Audubon Society has designated two IBAs within the study area, the Hockomock Swamp and the Freetown-Fall River State Forest/Southeastern Massachusetts Bioreserve, which includes the Acushnet Cedar Swamp State Reservation. These areas provide habitat for breeding birds of concern, as well as migratory and overwintering habitat for both wetland and upland bird species.

Mammals

Mammals are a diverse class of vertebrates that inhabit a wide variety of community types and niches. The list of mammals expected to be found within the study area was generated using the NEWILD computer program and supplemented with *New England Wildlife: Habitat, Natural History, and Distribution*[16] and other reference lists of mammals of Massachusetts.

With the exception of the northern water shrew (a state-listed species not identified by NHESP as inhabiting the Hockomock Swamp), the list includes all mammal species identified as likely inhabitants of the Hockomock Swamp in the publication *Hockomock Wonder Wetland*.[17]

Table 4.14-2 presents the list of mammal species that may find suitable feeding, breeding, and/or overwintering habitat within the study area. The Habitat Usage column lists each community type that may provide habitat for the individual species.

Reptiles, Amphibians, and Fish

Natural areas and waterways throughout the study area provide habitat for common and state-listed reptiles, amphibians, and fish. Previous studies have identified populations of some uncommon species of turtles such as the Eastern box turtle (*Terrapene carolina*), Blanding's turtle, spotted turtle (*Clemmys guttata*), and salamanders such as the blue-spotted salamander and the four-toed salamander (*Hemidactylium scutatum*) within the Hockomock Swamp wetlands. Table 4.14-3 lists the reptiles and amphibians that are likely to be found within the study area.

Table 4.14-2 Potential Mammalian Species Found Within the Study Area

Common Name	Scientific Name	Habitat Usage[1]
Virginia opossum	*Didelphis virginiana*	RM, SS, M, W/U, UD, C/D, P

1 Habitat: RM = Red maple; AWC = Atlantic white cedar; RM/AWC = red maple Atlantic white cedar mix; SS = shrub swamp; M = marsh/fen; W = open water; W/U = wetland/upland forested mix; UD = deciduous forested upland; UC = coniferous forested upland; C/D = upland mixed forest; AG = agricultural; D = developed; P = powerline; CL = cleared land (*e.g.,* gravel pit).

The Taunton River, in particular, is an important anadromous fish run that supports the Atlantic sturgeon (a federally and state-listed endangered species). Based on information provided by the DMF and DFW, there are 34 freshwater, anadromous, or diadromous fish recorded in the waterways crossed by the Stoughton Alternative. Although several other species have been recorded from the lower, saline, reaches of the Taunton River (bluefish, *Pomatomus saltatrix*; crevalle jack, *Caranx hippos*; winter flounder, *Pseudopleuronectes americanus*) these fish are not found in freshwater. Salt water extends 12.6 miles inland from the mouth of the Taunton River, which is approximately 2 miles below the point where the New Bedford Main Line crosses the Taunton River south of Ingells Street (Weir Junction). Table 4.14-4 lists the fish species that are documented by NHESP to occur within the study area.

Vernal Pools

Vernal pools are generally small, seasonally-inundated wetland depressions that lack a permanent, population of predatory fish, provide breeding habitat for amphibians (wood frogs, *Rana sylvatica*; and ambystomid salamanders), and may also be utilized by reptiles and other wildlife. Numerous vernal pools, including NHESP certified and potential vernal pools occur adjacent to the railroad embankment and other locations within the study area. These are small pools or seasonal ponding areas within bordering vegetated wetlands, or small isolated wetlands. Certified vernal pools (CVPs) are field verified and documented vernal pools that have been certified by the NHESP according to the *Guidelines for the Certification of Vernal Pool Habitat* (2009[18]). They are included as points in the MassGIS data layer. Potential vernal pools (PVPs) are unverified, vernal pool habitats with a MassGIS data layer produced by the NHESP to help locate likely vernal pools across the state. Potential vernal pools do not receive protection under the Massachusetts Wetlands Protection Act Regulations (310 CMR 10.00), or under any other state or federal wetlands protection laws. With the exception of a new vernal pool identified in 2009 (VP-13), no other vernal pools occur within the railroad embankment, although there are numerous vernal pools adjacent to the right-of-way. In several locations there are clusters of vernal pools, which may have higher wildlife habitat value than single, isolated pools.

Vernal pool investigations of the right-of-way were conducted in 2000-2001 for the Stoughton Alternative and were documented in the 2002 Final EIR. Additional surveys were conducted in the spring of 2008 and 2009 along the, Stoughton Line and Whittenton Branch. In 2008 the surveys were conducted within portions of the right-of-way along the inactive Stoughton Main Line in Stoughton, Easton, and Raynham. In 2009 the surveys were conducted within portions of the right-of-way in Stoughton, Taunton, Easton and Raynham along the inactive Stoughton Main Line and Whittenton Branch.

Table 4.14-4 Fish Species Potentially Found Within Waterways in the Study Area

Common Name	Scientific Name	Waterway [1, 2]
Alewife	*Alosa pseudoharengus*	Assonet River, Fall Brook, Mill River, Rattlesnake Brook, Taunton River
American eel	*Anguilla rostrata*	Assonet River, Black Brook, Cedar Swamp River, Cotley River, Fall Brook, Mill River, Pine Swamp Brook, Queset Brook, Rattlesnake Brook, Taunton River, Terry Brook, Whitman Brook
American shad	*Alosa sapidissima*	Taunton River
Atlantic menhaden	*Brevortia tyrannus*	Taunton River
Atlantic sturgeon	*Acipenser oxyrhynchus*	Taunton River

[18] Guidelines for the Certification of Vernal Pool Habitat (2009). Massachusetts Division of Fisheries and Wildlife. Natural Heritage and Endangered Species Program.

Common Name	Scientific Name	Waterway [1, 2]
Banded killifish	*Fundulus diaphanous*	Taunton River
Banded sunfish	*Enneacanthus obesus*	Cedar Swamp River, Fall Brook, Rattlesnake Brook
Black crappie	*Pomoxis nigromaculatus*	Mill River, Taunton River
Blacknose dace	*Rhinichthys atratulus*	Taunton River
Blueback herring	*Alosa aestivalis*	Assonet River, Fall Brook, Mill River, Rattlesnake Brook, Taunton River
Bluegill	*Lepomis macrochirus*	Assonet River, Mill River, Queset Brook, Taunton River
Brook trout	*Salvelinus fontinalis*	Cedar Swamp River, Rattlesnake Brook
Brown bullhead	*Ameiurus nebulosus*	Assonet River, Fall Brook, Mill River, Pine Swamp Brook, Rattlesnake Brook, Taunton River
Brown trout	*Salmo trutta*	Rattlesnake Brook
Carp	*Cyprinus empio*	Taunton River
Chain pickerel	*Esox niger*	Assonet River, Cotley River, Fall Brook, Mill River, Taunton River, Whitman Brook
Common shiner	*Notropis cornutus*	Mill River, Taunton River
Creek chubsucker	*Erimyzon oblongus*	Cedar Swamp River, Fall Brook, Taunton River
Fallfish	*Semotilus corporalis*	Taunton River
Gizzard shad	*Dorosoma cepedianum*	Taunton River
Golden shiner	*Notemigonus crysoleucas*	Fall Brook, Taunton River
Inland silverside	*Menidia beryllina*	Taunton River
Largemouth bass	*Micropterus salmoides*	Assonet River, Cotley River, Mill River, Pine Swamp Brook, Taunton River, Whitman Brook
Mummichog	*Fundulus heteroclitus*	Taunton River
Pumpkinseed	*Lepomis gibbosus*	Assonet River, Cotley River, Mill River, Pine Swamp Brook, Taunton River, Whitman Brook
Rainbow smelt	*Osmerus mordax*	Assonet River, Rattlesnake Brook, Taunton River
Rainbow trout	*Oncorhynchus mykiss*	Rattlesnake Brook
Redfin pickerel	*Esox americanus americanus*	Assonet River, Cedar Swamp River, Fall Brook, Mill River, Pine Swamp Brook, Rattlesnake Brook, Taunton River
Striped bass	*Morone saxatilis*	Taunton River
Swamp darter	*Etheostoma fusiforme*	Cedar Swamp River, Cotley River
Tessellated darter	*Etheostoma olmstedi*	Mill River, Queset Brook, Taunton River, Whitman Brook
Tiger trout	*Salmo trutta x Salvelinus fontinalis*	Rattlesnake Brook
White perch	*Morone americana*	Assonet River, Fall Brook, Rattlesnake Brook, Taunton River
White sucker	*Catastomus commersoni*	Taunton River
Yellow perch	*Perca flavescens*	Taunton River

Source: List of species and names of rivers and streams provided by NHESP in a letter dated January 9, 2009.
1 Currently NHESP has no fisheries survey information for Black Brook, Blue Hill River, Lovett Brook, Steep Brook or Terry Brook.
2 Beaver Brook, Rattlesnake Brook and Wading River are annually stocked in the spring with brook trout, brown trout, rainbow trout and/ or tiger trout.

During these investigations, several NHESP-identified potential vernal pools within 100 feet of the right-of-way were inspected for the presence of certification characteristics under NHESP guidance. Previously unidentified vernal pools were located and documented using GPS technology. A summary of results from these vernal pool investigations is included in Section 4.14.2.2. Some of the vernal pool point data available from GIS were found to be incorrectly located when compared to field verified locations and certification forms provided by NHESP. The correct locations for all field verified vernal pools are shown in the figures in Volume II (4.14-7 through 4.14-10).

In April 2009 vernal pool inspections were conducted along the Stoughton Line (within the Hockomock Swamp), in conjunction with NHESP staff. New vernal pools were identified along the Stoughton Line with sufficient evidence of obligate species to allow certification. NHESP has indicated that additional information on these pools will be provided once the certification forms are completed.

In 2010, field work began in order to identify and delineate all wetland resource areas along the Stoughton Alternative. At that time, any additional vernal pools not found during earlier surveys were identified. Visual searches were conducted along the right-of-way to identify any previously unidentified vernal pools. Several NHESP identified potential vernal pools within 100 feet of the right-of-way were inspected for the presence of certification characteristics under NHESP guidance. Previously unidentified vernal pools were located and documented. Some of the vernal pool point data available from MassGIS were found to be incorrectly located when compared to field verified locations and certification forms provided by the NHESP. The locations of all certified, potential, and field verified vernal pool are shown in Figures 4.14-7 through 10.

The June 29, 2011 Secretary's Certificate on the DEIR required a more expansive level of vernal pool assessment, including indirect impacts to upland habitat for vernal pools up to 750 feet on either side of the right-of-way. It is not practicable to conduct complete searches of the entire area within 750 feet from the right-of-way, due to the large area which would require review (approximately 15 square miles) as well as the fact that the vast majority of the land is under private ownership. However, all known certified and potential vernal pools within 750 feet of the right-of-way were used in the impact analysis.

Wildlife Action Plan

The Comprehensive Wildlife Conservation Strategy (CWCS) describes 22 habitats and proposes conservation strategies for each of them. Eleven of these habitats are found within the study area and include:

- Large and mid-sized rivers
- Upland forest
- Large unfragmented landscape
- Small streams
- Shrub swamps
- Forested swamps

- Lakes and ponds
- Young forests and shrublands
- Riparian forest
- Vernal pools
- Marshes and wet meadows

4.14.2.2 Existing Conditions within the Study Corridor

The following describes existing conditions and identifies areas along each segment of the alternatives corridors that have the potential to support important biodiversity elements such as plant communities, wildlife habitat, birds, aquatic life, and fish. These areas are notable because they provide a higher biodiversity value than other segments of the alternatives corridors.

Southern Triangle Study Area (Common to All Rail Alternatives)

All rail alternatives would require improvements to the existing active rail infrastructure south of Cotley Junction in Taunton (the New Bedford Main Line and the Fall River Secondary) (Figures 4.14-3a through e, 4.14-4a through c, 4.14-7e, 4.14-8a through d, and 4.14-9a through c).

Both the New Bedford Main Line and Fall River Secondary are active freight lines with ballasted right-of-way, tracks, and ties. There are culverts that convey streams underneath the embankment. The right-of-way itself does not provide suitable habitat wildlife and the tracks and ties prevent turtles, amphibians, and small mammals from moving across the right-of-way except through the culverts.

New Bedford Main Line

The New Bedford Main Line passes through several areas of Core Habitat including the Acushnet Cedar Swamp and the Assonet Cedar Swamp (BM1229). It is adjacent to one Living Water (LW239) in New Bedford and crosses rivers and streams that are considered important fisheries habitat.

BioMap Core Habitat

BioMap Core Habitat (BM1229) is a large polygon that includes the Assonet Cedar Swamp and the Acushnet Cedar Swamp, which are crossed by the New Bedford Main Line, and the Southeastern Massachusetts Bioreserve, Freetown-Fall River State Forest, which is crossed by the Fall River Secondary.

Assonet Cedar Swamp (BM1229)—Located in Freetown, the Assonet Cedar Swamp is sometimes referred to as the Great Cedar Swamp and borders the Cedar Swamp River and the Assonet River south of Myricks Junction. The extensive wetland contains one of the largest Atlantic white cedar swamps in the state, and supports numerous state-listed species. The Assonet Cedar Swamp includes the Assonet Cedar Swamp Wildlife Sanctuary, a 1,000-acre parcel of conservation land owned by the Massachusetts Audubon Society in Lakeville. The New Bedford Main Line crosses (approximately 5,150 feet) and abuts (approximately 4,550 feet) the Assonet Cedar Swamp for a total of approximately 2 miles (Figures 4.14-3b-c).

Acushnet Cedar Swamp (BM1229)—The Acushnet Cedar Swamp State Reservation is an approximately 1,000-acre property located in New Bedford and Dartmouth, north of the New Bedford Airport. It is an outstanding example of an Atlantic white cedar swamp and provides habitat for state-listed rare wetlands wildlife and other state-listed rare, endangered, or special concern species. This is one of eight cedar swamps in public ownership in Massachusetts, and has been designated by the U.S. Department of the Interior, National Park Service as a National Natural Landmark (36 CFR Part 62). The existing New Bedford Main Line, currently active for freight rail service, forms a major portion of the eastern boundary of the Reservation in New Bedford (Figures 4.14-3c-d). In New Bedford, the Acushnet Cedar Swamp encompasses Living Water Core Habitat (LW239).

Living Waters

The New Bedford Main Line is adjacent to Living Water Core Habitat (LW239) that includes the Acushnet Cedar Swamp and Turner Pond. This Living Water provides habitat for the rare coastal swamp amphipod and the rare American clam shrimp (Figure 4.14-3d). It abuts the track for approximately 0.6 mile south of Route 140 in New Bedford.

Fisheries Habitat

The New Bedford Main Line crosses the Cotley River, Cedar Swamp River, and Fall Brook, which are all important fisheries habitats. Table 4.14-4 lists the fish species that are documented by the Massachusetts Department of Fish and Wildlife to occur within these stream systems.

Vernal Pools

A discussion of vernal pools along the New Bedford Main Line is included in the narrative for the Stoughton Alternative.

Fish and Wildlife Passage

A discussion of fish and wildlife passage along the New Bedford Main Line is included in the narrative for the Stoughton Alternative.

Other Important Habitat Areas

The New Bedford Main Line crosses and is adjacent to large wetland areas located in Berkley, between Route 24 and Myricks Street (Figure 4.14-3a). These wetlands areas are unfragmented open space that could be important wildlife habitat because they may be used as dispersal, migration, breeding, foraging, and as bird stopover areas.

Fall River Secondary

The Fall River Secondary is adjacent to several areas of Core Habitat that includes Forge Pond (BM1232) and the Southeastern Massachusetts Bioreserve, Freetown-Fall River State Forest (BM1229). It is not adjacent to any Living Waters, however it crosses rivers and streams that are considered important fisheries habitats.

BioMap Core Habitat

This section includes a description of the BioMap Core Habitat adjacent to and crossed by the Fall River Secondary.

Forge Pond (BM1232)—Forge Pond is an irregularly shaped surface waterbody located mainly on the southwestern side of the Fall River Secondary in Freetown. A wetland complex of trees, shrubs, and emergent vegetation exists between the bank of the pond and the track in several areas, most notably along the northern portion of the pond. In this area, the wetland complex borders the tracks for approximately 1,100 feet. The track abuts the Forge Pond Core Habitat for approximately 400 feet in Freetown (Figure 4.14-4a).

Freetown-Fall River State Forest (BM1229)—BioMap Core Habitat (BM1229) is a large polygon that includes the Southeastern Massachusetts Bioreserve and Freetown-Fall River State Forest, which are adjacent to the Fall River Secondary, and includes the Assonet Cedar Swamp and Acushnet Cedar Swamp, which are only crossed by the New Bedford Main Line. The Fall River Secondary crosses the Assonet River, which runs through the Assonet Cedar Swamp.

The Freetown-Fall River State Forest is a 5,441-acre property with access from Slab Bridge Road in Freetown. The state forest provides recreational facilities, including a picnic area and 50 miles of unpaved roads and trails used for hiking, mountain biking, horseback riding, and snowmobiling. Hunting and fishing are also popular uses of the state forest, particularly Rattlesnake Brook, which is stocked with brook trout. None of the active public recreation areas or trails is adjacent to the tracks, which are currently used for freight rail service. The Freetown-Fall River State Forest is bounded on the northwest by the existing Fall River Secondary for approximately 1.4 miles in Freetown (Figures 4.14-4a-b). The state forest is part of the Southeastern Massachusetts Bioreserve.

Living Waters

The Fall River Secondary is not adjacent to any Living Waters, however it crosses rivers and streams that are considered important fisheries habitat.

In Freetown, the Fall River Secondary crosses Rattlesnake Brook at the same location where it is crossed by Route 24. North of this location, the track abuts the eastern bank of the Assonet River between Forge Road and Beechwood Road. Farther north in Lakeville, the track crosses the Assonet River. In none of these locations is the track adjacent to (within 100-feet of the track centerline), nor does it cross the areas of Core Habitat that have been designated for sections of Rattlesnake Brook (LW321) and the Assonet River (LW330) (Figures 4.14-4a-b).

Fisheries Habitat

The Fall River Secondary crosses the Assonet River, Rattlesnake Brook, and Terry Brook (Figures 4.14-4a-b) and is adjacent to the Taunton River. These waterways all provide important fisheries habitat. Table 4.14-4 includes fisheries survey results for these habitats.

Vernal Pools

A discussion of vernal pools along the Fall River Secondary is included in the narrative for the Stoughton Alternative.

Fish and Wildlife Passage

A discussion of fish and wildlife passage along the Fall River Secondary is included in the narrative for the Stoughton Alternative.

Other Important Habitat Areas

The Fall River Secondary is not adjacent to nor does it cross any other large unfragmented habitat or protected open spaces.

Stoughton Alternative

The Stoughton Alternative, north of Cotley Junction, includes improvements to existing active freight or rail lines (track sections north of Stoughton Station and from Dean Street to Cotley Junction) and track construction on out-of-service or abandoned rights-of-way (between Stoughton Station and Dean Street or between Whittenton Junction and Route 138 for the Whittenton variant of the Stoughton Alternative (Whittenton Alternative). All alternatives that use the Stoughton line (including the Whittenton variant) would include constructing a trestle through part of the Hockomock Swamp to reduce impacts to wetlands, biodiversity, and rare species. The Stoughton Electric and Diesel Alternatives are illustrated in Figures 4.14-5a-e and 4.14-7a-e.

The Stoughton Line is an inactive line without tracks and ties in most areas. There are culverts that convey streams underneath the embankment. In addition to the culverts, the right-of-way itself provides suitable migratory habitat for wildlife because there are no tracks and ties to prevent turtles, amphibians, and small mammals from moving across the right-of-way. However, the right-of-way does not likely provide suitable nesting, breeding, or foraging habitat for wildlife. This is in part due to disturbance caused by frequent, although unauthorized use of the right-of-way by pedestrians, bicycles, and in particular, all-terrain vehicles (ATVs), which also cause erosion.

Both the Stoughton Alternatives (diesel/electric) (as well as the Whittenton Variant) cross through a Core Habitat polygon that includes the Hockomock Swamp ACEC (BM1166). Unlike the Whittenton variant, the Stoughton Alternatives cross the Pine Swamp (BM1196) in Raynham. Both the Stoughton Alternatives and the Whittenton Variant (Whittenton Alternative) cross the Taunton River near a reach that is mapped as a Living Water Core Habitat (LW080). The Taunton River is identified as providing important fisheries habitat.

BioMap Core Habitat

This section includes a description of the BioMap Core Habitat crossed by the Stoughton Line.

Hockomock Swamp (BM1166)—The Hockomock Swamp ACEC includes approximately 16,950 acres of land in Bridgewater, Easton, Norton, Raynham, Taunton, and West Bridgewater (Figures 4.14-5c-d). The ACEC is fragmented by several major transportation corridors, including Routes 24, I-495, 138, 106, and other major roadways, and it includes substantial upland areas within the watershed of the Hockomock Swamp. These uplands include land developed in commercial and residential uses as well as undeveloped forested upland and farmland.

Much of the Hockomock Swamp portion of the ACEC (approximately 5,000 acres) is owned by the Massachusetts Division of Fisheries and Wildlife as the Hockomock Swamp Wildlife Management Area (WMA). The DCR describes the ACEC is one of the most extensive inland wildlife habitats in southeastern

Massachusetts and as the largest vegetated freshwater wetland system in Massachusetts. The wetland system includes Hockomock Swamp, Dead Swamp, Titicut Swamp, and Little Cedar Swamp.[19]

The ACEC provides habitat for at least 13 species listed as rare, endangered, or of special concern by the NHESP, and contains several different plant communities. The Atlantic white cedar swamp and fen wetland communities scattered throughout the ACEC are considered to be outstanding examples of these unique natural communities. The Atlantic white cedar community is found on the western side of the embankment. Because the railroad berm controls the flow of water from west to east, higher surface water elevations are maintained west of the embankment and are associated with the Atlantic white cedar community. The portion of the wetland east of the railroad berm contains a red maple-dominated wetland. The hydrology of this area is controlled by the Route 138 embankment.

This wetland complex includes two Core Habitats (BM1166 and BM1168). The Stoughton Line crosses the Hockomock Swamp for approximately 1.6 miles and the BioMap Core Habitat (BM1166) for approximately 3 miles (Figures 4.14-5c-d). The Stoughton Line is not adjacent to the Core Habitat (BM1168).

Pine Swamp (BM1196)—Pine Swamp is a 275-acre wetland system located in western Raynham and includes several properties that are owned by the Town of Raynham Conservation Commission (Figure 4.14-5d). This area consists of forested and marsh wetlands, is located within mapped estimated habitat of several rare wetland species, and supports an Atlantic white cedar swamp community. The right-of-way for the Stoughton Alternatives (diesel, electric)) crosses the both the Pine Swamp and Core Habitat (BM1196) for approximately 1 mile between King Phillip Street and East Britannia Street.

Living Waters

The Stoughton Line is adjacent to Living Water Core Habitat (LW080) near a reach of the Taunton River that provides habitat for the federally listed Atlantic sturgeon. The right-of-way crosses this section of the Taunton River for approximately 125 feet, south of Weir Junction in Taunton (Figure 4.14-3a). North of Weir Junction, the Stoughton Alternatives (diesel, electric) cross the Taunton River three more times on a series of bridges located upstream from the area mapped as Living Water (LW080) (Figure 4.14-5e).

Fisheries Habitat

The Stoughton Line crosses Whitman Brook, Queset Brook, Black Brook, Pine Swamp Brook, Taunton River, and the Mill River, which are all important fisheries habitats. Table 4.14-4 includes fisheries survey results for these habitats. According to the Massachusetts Department of Fish and Wildlife comment letter on the DEIS/DEIR, fisheries surveys of the Mill River yielded 10 species, including American eel (*Anguilla rostrata*), black crappie (*Pomoxis nigromaculatus*), bluegill (*Lepomis macrochirus*), brown bullhead (*Ameiurus nebulosus*), chain pickerel (*Esox niger*), common shiner (*Notropis cornutus*), largemouth bass (*Micropterus salmoides*), pumpkinseed (*Lepomis gibbosus*), redfin pickerel (*Esox americanus americanus*) and tessellated darter (*Etheostoma olmstedi*).

[19] Hockomock Swamp ACEC website: (http://www.mass.gov/dcr/stewardship/acec/acecs/l-hcksmp.htm).

Breeding Bird Diversity along the Stoughton Corridor

In response to requirements of the Secretary's Certificate, as well as other comments received in the DEIS/DEIR, breeding bird surveys and other studies conducted to refine the wildlife impact assessment and mitigation plans. The updated evaluation of breeding bird diversity includes a description of key avian habitats and an updated list of breeding birds (identifying area-sensitive bird species as well as wetland-dependent birds) likely to occur along the Stoughton Alternative.

Key Avian Habitats

Although breeding birds occur along the entire South Coast Rail corridor, several key areas for the protection of bird diversity have been identified by the Massachusetts Audubon Society (Mass Audubon) and the Natural Heritage and Endangered Species Program (NHESP) Biomap program. This section describes these key habitat areas and provides an update of the breeding birds likely to occur in the key avian habitat areas.

An Important Bird Area (IBA) is an area that provides important habitat to one or more species of breeding, wintering, and/or migrating birds. These areas are designated as part of an international effort to protect bird habitat around the world. The Massachusetts Audubon Society has designated two IBAs within the study area: the Hockomock Swamp and the Freetown Fall River State Forest/Southeastern Massachusetts Bioreserve. Other key bird habitats are large, relatively intact forested areas and include Pine Swamp in Raynham, the Assonet Cedar Swamp in Lakeville, and the Acushnet Cedar Swamp in New Bedford.

Hockomock Swamp IBA—The Hockomock Swamp IBA is a 5,126 acre area located in Bridgewater, Easton, Norton, Taunton, West Bridgewater, Bridgewater, and Plymouth. It includes three state owned wildlife management areas (WMA): the Hockomock Wildlife Management Area, the Wilder Wildlife Management Area, and the West Meadows Wildlife Management Area. This IBA provides important migratory/stopover habitat as well as nesting habitat.

The area has been reported to contain nine breeding and/or wintering/migrant state-listed species, and at least 47 regional and five state high conservation priority species. Very abundant species are gray catbird, northern waterthrush, common yellowthroat, swamp sparrow, common grackle, and veeries. State-listed species within this IBA include: grasshopper sparrow, short-eared owl, upland sandpiper, common moorhen, king rail, sharp shinned hawk, northern harrier, least bittern, and pied-billed grebe.

The major habitat types found within this IBA include oak-conifer forest, cultivated grassland, cultivated field, emergent freshwater wetland, palustrine woodland swamp, shrub-scrub wetland, lake/pond, and river/stream.

Freetown Fall River State Forest/ Southeastern Massachusetts Bioreserve IBA—The Freetown Fall River State Forest/Southeastern Massachusetts Bioreserve IBA is a 15,000 acre area located in the towns of Freetown, Fall River, and Bristol. It includes the Freetown Fall River State Forest, the Acushnet Cedar Swamp, and the Southeastern Massachusetts Bioreserve. This area supports important avian habitat diversity, especially in the Rattlesnake Brook area, and provides important migratory/stopover habitat as well as nesting habitat. Because of the Bioreserve designation, there is a focus on habitat management, research, and monitoring of flora and fauna. Some of the bird monitoring efforts include: Christmas Bird Counts, spring migration bird counts, Breeding Bird Surveys, and Biodiversity Day events. Christmas Bird Counts and Breeding Bird Surveys have been conducted since 1970.

The area has been reported to contain one breeding and/or wintering/migrant state listed species, and at least seven regional and one state high conservation priority species. Very abundant species include the Eastern towhee, ovenbird, and prairie warbler. The migrant state listed species reported to use the IBA is the Northern parula.

The major habitat types found within this IBA include northern hardwoods forest, oak-conifer forest, pitch pine/scrub oak, early successional shrubland, power line, shrub-scrub wetland, and river/stream.

Pine Swamp—Pine Swamp is a 275 acre wetland system in western Raynham that includes several properties owned by the Town of Raynham Conservation Commission. This area consists of forested and marsh wetlands, is located within mapped estimated habitat of several rare wetland species, and supports an Atlantic white cedar swamp community. The right-of-way crosses Pine Swamp for approximately 1 mile between King Phillip Street and East Britannia Street.

Assonet Cedar Swamp—As previously discussed as a BioMap Core Habitat, the Assonet Cedar Swamp in Lakeville and Freetown is considered key bird habitat.
Acushnet Cedar Swamp

As previously discussed as a BioMap Core Habitat, the Acushnet Cedar Swamp State Reservation located in New Bedford and Dartmouth, is considered key bird habitat

Breeding Bird Diversity

A list of potential breeding birds along the Stoughton alignment (including the Southern Triangle) was developed using the Mass Audubon Breeding Bird Atlas 2 data. Data for atlas blocks in five areas were reviewed: Hockomock Swamp (Blocks Brockton 09, Taunton 07); Pine Swamp (Taunton 08); Assonet Cedar Swamp (Somerset 11); Freetown-Fall River State Forest (Somerset 09, 12); Acushnet Cedar Swamp (New Bedford North 02). Birds listed as Confirmed, Probable, or Possible breeders were assumed to be potential breeding birds along the Stoughton corridor.

As described above, the breeding bird atlas block lists were used to develop a list of potential breeding bird species for each of the key habitat areas (the Hockomock Swamp, Pine Swamp, the Assonet Swamp, Freetown-Fall River State Forest, and the Acushnet Cedar Swamp). As shown in Table 4.14-1 , there are potentially 101 breeding bird species along the Stoughton Alternative corridor, in the key habitat areas.

Each atlas block is 1/12 of a USGS topographic quad, and covers 10 square miles. The breeding bird data for each block therefore includes substantial areas that are not adjacent to the rail corridor, and includes a range of habitats (suburban neighborhoods, open fields, ponds and lakes, marshes, upland forest, forested swamps). This diversity of habitats is reflected in the list presented in Table 4.14-1, which includes suburban birds (cardinal [*Cardinalis cardinalis*], robin [*Turdus migratorus*], chipping sparrow [*Spizella passerine*], chimney swift [*Chaetura pelagica*]); birds of ponds and lakes (mute swan [*Cygnus olor*], osprey [*Pandion haliaetus*], kingfisher [*Ceryle alcyon*]); birds of marshes (red-winged blackbird [*Agelaius phoeniceus*], marsh wren [*Cistothorus palustris*], yellow warbler [*Dendroica petechial*]), birds of fields and shrublands (bluebird [*Sialia sialis*], savannah sparrow [*Passerculus sandwichensis*], song sparrow [*Melospiza melodia*], indigo bunting [*Passerina cyanea*]); and birds of upland dry forest (whip-poor-will [*Caprimulgis vociferous*], Eastern towhee, pine warbler [*Dendroica pinus*]).

The primary bird species of concern are the forest interior species, birds that require large areas of forest (upland or wetland) for nesting. These include such species as barred owl [*Strix varius*], broad-winged hawk [*Buteo platypterus*], veery [*Catharus fuscescens*], wood thrush [*Hylocichla mustelina*], black-and-white warbler [*Mniotilta varia*], American redstart [*Setophaga ruticilla*], and scarlet tanager [*Piranga olivacea*]. As shown in Table 4.14-1, the Acushnet Cedar Swamp area has the highest number (16) of these forest interior birds, while the other areas are similar in the level of diversity of forest interior birds, with 9 to 11 species reported in each area.

There are 18 wetland-dependent bird species reported from these key habitat areas. These species occupy a wide range of breeding habitats, including open water (osprey, great blue heron [*Ardea Herodias*], mute swan), marshes (red-winged blackbirds), and shrub swamps (common yellowthroat, swamp sparrow). None are restricted to forested wetlands. As shown in Table 4.14-1, the majority of the wetland-dependent species occur in all of the key habitat areas.

Vernal Pools

In 2000-2001, the South Coast Rail right-of-way for the Stoughton Alternative was delineated for wetlands and investigated for the presence of vernal pool habitat. During these investigations, 16 certified vernal pools and 14 uncertified vernal pools were identified adjacent to the Stoughton Line and documented in the 2002 Final EIR. Some of the vernal pool point data available from GIS were found to be incorrectly located when compared to field verified locations.

Previous vernal pool surveys were supplemented by additional surveys conducted in 2008 and 2009. The 2008 investigations included surveys of the right-of-way in Stoughton, Easton, and Raynham along the inactive Stoughton Main Line. Three previously unidentified vernal pools were observed and documented adjacent to the right-of-way in Easton and Raynham (VP-10, VP-11, and VP-12). The 2009 investigations included surveys of the right-of-way in Stoughton, Taunton, Easton, and Raynham along the inactive Stoughton Main Line and Whittenton Branch. Three additional vernal pools were identified and documented adjacent to the right-of-way in Easton and Raynham (VP-13, PVP-23791, and PVP-25089). These vernal pools were mapped using GPS technology and are described below.

On April 7, 2009 additional vernal pools inspections were conducted along the Stoughton Line in Easton and Raynham in conjunction with NHESP staff. During this field visit NHESP inspected certified, potential, and previously-unidentified vernal pools found between Depot Street and Bridge Street (Hockomock Swamp). The following is a summary of this effort:

Approximately three new vernal pools, illustrated in Figures 4.14-7c-d as NHESP-1, NHESP-2, and NHESP-3, were identified with sufficient evidence of obligate species (wood frogs, spotted salamanders, and fairy shrimp) to allow certification.

Three previously identified potential vernal pools (PVP-7256, PVP-7257, and PVP-20158) had sufficient evidence of obligate species to allow certification. All certified vernal pools had evidence of obligate species.

In 2010, field work began in order to identify and delineate all wetland resource areas along the Stoughton Alternative. At that time, any additional vernal pools not found during earlier surveys were identified. Visual searches were conducted along the right-of-way to identify any previously unidentified vernal pools. Several NHESP identified potential vernal pools within 100 feet of the right-of-way were inspected for the presence of certification characteristics under NHESP guidance. Previously unidentified

vernal pools were located and documented. Some of the vernal pool point data available from MassGIS were found to be incorrectly located when compared to field verified locations and certification forms provided by the NHESP. The locations of all certified, potential, and field verified vernal pool are shown in Figures 4.14-7-10.

The Secretary's Certificate required a more expansive level of vernal pool assessment, including indirect impacts to upland habitat for vernal pools up to 750 feet on either side of the right-of-way. It is not practicable to conduct complete searches of the entire area within 750 feet from the right-of-way, due to the large area which would require review (approximately 15 square miles) as well as the fact that the vast majority of the land is under private ownership. However, all known certified and potential vernal pools within 750 feet of the right-of way were used in the impact analysis.

Existing Vernal Pools along the Stoughton Alternative inclusive of the Southern Triangle—Numerous vernal pools are present within the right-of-way and in other locations within the study area. Several vernal pools occur adjacent to the railroad embankment. There are clusters of vernal pools in several locations that may have higher wildlife habitat value than single, isolated pools. Table 4.14-5 summarizes the vernal pools that have at least some portion inside the right-of-way, pools within 100 feet of the right-of-way, and pools within 750 feet of the right-of-way.

The Stoughton Alternative passes through four large vernal pool complexes, consisting mostly of PVPs. Vernal pools are present on both sides of the right-of-way in Easton, immediately south of the proposed North Easton Station site (Figure 4.14-7b). Movement of vernal pool amphibians between pools in this area may occur to some degree, but this movement is likely to be constrained by the presence of the existing, abandoned tracks (rails) in this area. A large vernal pool complex is present within Hockomock Swamp in Easton, south of Foundry Street, extending to the powerline corridor (Figure 4.14-7c). Several discrete vernal pools are present south of the powerline corridor. Large areas of the Hockomock Swamp support breeding of vernal pool amphibians and spotted turtles although they do not meet the regulatory definition of vernal pools. Movement between these areas is currently unrestricted. These sections of the out-of-service right-of-way are heavily used by All Terrain Vehicles (ATVs), which drive through the vernal pools in serpentine and circuitous routes and adversely affect the habitat of vernal pool fauna, particularly during breeding, egg and larval stages. A group of PVPs is mapped within the Hockomock Swamp ACEC in Raynham, north of Bridge Street (Figure 4.14-7d). The right-of-way in this area is open and unvegetated, but does not have tracks or ties. Vernal pool complexes are also present along both sides of the right-of-way south of Pine Swamp in Raynham between East Brittania Street and Thrasher Street, and between Thrasher Street and Winter Street (Figure 4.14-7e).

The New Bedford Main Line and Fall River Secondary pass by relatively few vernal pools, and the pools along these lines do not form clusters. Connectivity between these pools is often already fragmented by existing roads.

Table 4.14-5 Summary of Vernal Pools Inclusive of the Southern Triangle

Fish and Wildlife Passage

A detailed inventory of bridges and culverts was conducted to identify the location, condition, and function of each structure. Dimensions, construction materials, and railroad bed characteristics (such as condition and depth of cover) were recorded. For this biodiversity assessment, the subset of bridges and culverts with potential ecological value was determined by reviewing wetland mapping (as depicted in the Abbreviated Notice of Resource Area Determination [ANRAD] for each municipality), surrounding land use (as visible in aerial photographs), and other ecological setting features, as modeled by the University of Massachusetts' Conservation Assessment and Prioritization System CAPS, of the complete bridge and culvert inventory. The CAPS model background information is provided in Section 4.14.3.1 Impact Assessment Methodology. The inventory of this subset of bridges and culverts is provided in Appendix 4.14-A, and summarized in this section.

There are 128 structures (23 bridges and 105 culverts) along the Stoughton Alternative alignment (comprised of the Stoughton Line, New Bedford Main Line, and Fall River Secondary) that may have biodiversity value by connecting ecosystems, which can allow fish and wildlife to pass from one side of the tracks to the other. Many of these structures also have a hydrologic function, allowing water to flow under or through the railroad structure (subgrade, ballast, ties, and tracks). Bridges that convey roads under or over the railroad bed would also be improved for the project but do not have an ecological function connecting ecosystems and are therefore not included in this biodiversity evaluation. Bridges and culverts that have been replaced prior to the South Coast Rail project are also not included in this biodiversity evaluation, as are 29 culverts within the right-of-way that do not cross under the railroad bed (are parallel to it) and therefore do not connect ecosystems bisected by the railroad.

The distribution of these existing 128 structures with potential ecological value between the three rail segments is indicated in Table 4.14-6. A detailed inventory of the structures is provided in Appendix 4.14-A. Figures 4.14-11 through 4.14-13 depict existing bridge and culvert locations.

Table 4.14-6 Summary of Bridges and Culverts

Structure	Stoughton Line	New Bedford Main Line	Fall River Secondary	Total
Bridges	10	6	7	23
Culverts	50	28	27	105
Total	60	34	34	128

Portions of the three railroad lines were originally constructed in the mid-1800s and many of the culverts may date from that period. The current major bridges, such as those over the Taunton River in Taunton, were constructed in the early 1900s.[20] Many of these structures would be replaced to meet modern engineering standards.

The bridges along the Stoughton Alternative are open-bottom structures with abutments or pilings supporting a deck stringer, girder, slab, or trestle to which the tracks are affixed. Most of the bridges considered in this biodiversity evaluation convey the tracks over perennial streams, rivers, or ponds and therefore allow unimpeded passage of aquatic species (fish and amphibians). These over-water bridges generally accommodate flood flow. Some bridges are located in upland areas and may have originally conveyed the tracks over farm roads, and can now serve as open passage for wildlife on the abandoned roads; a subset of these bridges are located along the Taunton River in Fall River and also allow flood access to land subject to coastal storm flowage (LSCSF), as shown in Table 4.14-7. The majority of the bridges range in length from 12 to 36 feet; the longest bridges are the four over the Taunton River in Taunton (Figure 4.14-11e), ranging from 113 to 176 feet long, on the Stoughton Line. Another substantial bridge, 64 feet long, crosses the Cedar Swamp River in Freetown (Figure 4.14-12b) on the Fall River Secondary. Construction features of each bridge are provided in the culverts along the Stoughton Alternative are open- or closed-bottom box or pipe structures beneath the tracks, covered with a layer of railroad bed ballast. Most of the culverts along the alignment are stone boxes; others are cast iron pipe, ductile iron pipe, corrugated metal pipe, or other materials. The culverts considered in this biodiversity evaluation provide a variety of hydrologic functions, as indicated in Table 4.14-8 and Appendix 4.14-A.

Culverts providing upland drainage accommodate stormwater flow but are otherwise dry. Wetland equalization functions maintain surface water levels in adjoining wetlands. Intermittent or perennial streams are conveyed by some culverts, while others connect parts of a pond bisected by the railroad.

Some of the culverts along the alignment are collapsed, buried, or washed out and no longer perform their original hydrologic function or any ecological function. Others are submerged, either continuously or seasonally, and may no longer perform their original hydrologic function but currently allow water flow and fish or amphibian passage. At some culvert locations, the railroad bed has dammed surface water flow, creating a pond or wetland on the upstream side, especially where the culvert has collapsed. Culverts at these locations maintain water levels in the upstream pond or wetland.

[20] A number of bridges over or under roadways were replaced within the last 15 years.

Table 4.14-7 Bridge Features

Bridge	Figure Number	Crosses	Type	Number of Spans	Length (feet)
Stoughton Line					
Forge Pond	4.14-11a	Perennial Pond	Stone arch	1	29

Other Important Habitat Areas

The Stoughton Line crosses and is adjacent to large wetland and upland areas in Stoughton (adjacent to Stoughton Memorial Conservation Land), and in Easton, between River Terrace and Partridge Way and between Baldwin Street and Prospect Street (Figures 4.14-5b-c). These wetlands and wooded upland areas are mostly unfragmented open space that could be important wildlife habitat because they may be used as dispersal, migration, breeding, foraging, and as bird stopover areas.

Stoughton Memorial Conservation Land—The Town of Stoughton's Memorial Conservation Land (which includes the Bird Street Conservation Lands) is a 675-acre parcel west of the Stoughton Line right-of-way, extending from Plain Street to the Easton town line and west of the Bird Street Conservation Area (which is not within 0.5 mile of the corridor). The Stoughton Conservation Memorial Lands represent the largest contiguous conservation area owned by the Town of Stoughton.[21]

The majority of the land is wooded, but it also contains large areas of open fields. The area supports a variety of habitats, including a former quarry, old fields, a pond, marshes, forested wetlands, and forested uplands. The primary access to the property is off Bird Street. The area extends to the MBTA right-of-way in two locations, with approximately 1,500 feet of frontage on the right-of-way (Figure 4.14-5b). One location is a narrow strip where the railroad closely parallels Route 138 south of Morton Street. The second location is south of Totman Farm Road, extending to the Easton town line west of the right-of-way. The majority of the area and all of the developed trail system are more than 1,000 feet from the right-of-way and it does not include any BioMap Core Habitat. This area contains a cluster of potential vernal pools.

Whittenton Alternative

The Whittenton Alternative runs predominantly along the same course as the Stoughton Alternative. The Whittenton Alternative is different from the Stoughton Alternative only along a portion of right-of-way between Raynham Junction and Weir Junction, a length of approximately 5.8 miles. A section of the Whittenton Alternative, known as the Whittenton Branch, diverges from the Stoughton Line at Raynham Junction and travels through Raynham and Taunton for approximately 3.4 miles to Whittenton Junction. This section of track is currently inactive. At Whittenton Junction, the track joins the Attleboro Secondary, an active rail line, for approximately 2.4 miles to Weir Junction at the beginning of the New Bedford Main Line. The Whittenton and Stoughton Alternatives run the same course on the Stoughton Line from Canton to Raynham Junction. The New Bedford Main Line and the Fall River Secondary are

[21] Town of Stoughton Open Space and Recreation Plan, prepared by Horsley Witten Group, public review draft April 2006, p. 38.

also identical for both alternatives. Figures 4.14-6 and 4.14-10 show the Whittenton Branch and Attleboro Secondary segments of the Whittenton Alternative.

The right-of-way corridor in Raynham is approximately 1.2 miles long and is characterized by a wide, well-worn path used by ATVs, horses, mountain and motor bikes, and pedestrians. A power line runs down the eastern edge of the right-of-way from Raynham Junction to King Philip Street, creating a canopy gap at least 20 feet wide in most places. Although the western side of the right-of-way passes by a large wetland area (Wetland RWB 02), the majority of the eastern side of the right-of-way from Raynham Junction to King Philip Street is characterized by residential development. From south of King Philip Street to the municipal border between Raynham and Taunton, the right-of-way passes through a highly disturbed area, currently the site of a construction and demolition (C&D) debris disposal facility that has encroached onto the railroad right-of-way. New England Recycling, Inc. of Taunton stores the C&D debris at the Raynham Facility, which abuts the railroad right-of-way and has an address of 138 (Rear) Broadway in Raynham. Disposal of C&D debris on the railroad right-of-way is not an authorized use of the land. The right-of-way is currently occupied by what appears to be material containing stumps, compost, sand, gravel, boulders, and minor amounts of solid waste and debris. The disposal facility operator has indicated that this material is frequently relocated and new material brought into the site and would be relocated at the request of MassDOT.

For these reasons, biodiversity issues are fairly limited in scope along the Raynham section of the Whittenton Branch. Because of the canopy gap and the development on the eastern side of the right-of-way, no large areas of wetland or upland habitat would be fragmented by the railroad. No endangered species habitat exists along the right-of-way, and no perennial streams are crossed.

The Taunton section of the right-of-way is approximately 2.2 miles long. From the municipal border between Raynham and Taunton, the right-of-way passes by Prospect Hill Pond and travels through a wooded upland for approximately 0.6 mile. The path in this section remains wide with a canopy gap, and several side ATV trails branch off from the right-of-way. This section of the right-of-way also passes by a wetland area (Wetland TWB 09) containing Atlantic white cedar, a state listed rare species. The right-of-way then enters another developed area and crosses Bay and Whittenton Streets, passing close by several residential properties to the east as well as an industrial land parcel to the west, for approximately 0.6 mile. South of Whittenton Street, the right-of-way has been widened into an access road which was previously used to access a stone quarry site to the west. The roadway is approximately 20 feet wide. The right-of-way then crosses the Mill River and Warrren Street, a distance of approximately 0.3 mile. South of Warren Street, the right-of-way follows the access road for another 0.3 mile. Finally, the right-of-way branches off from the access road, and for the remaining 0.3 mile, it travels through an area of denser vegetation, with a narrow path approximately 6 to 8 feet wide and a closed canopy in places. The entire 0.6 mile area south of Warren Street has also been designated as eastern box turtle habitat by the Natural Heritage and Endangered Species Program (NHESP). Threatened and endangered species are discussed in detail in Chapter 4.15.

Prospect Hill Pond and the surrounding forested upland provide wildlife habitat, despite nearby ATV use of the area. The Mill River is a perennial stream and provides a wildlife corridor for both fish and birds. Finally, the area south of Warren Street has several large wetland areas adjacent to it that ultimately drain to the Mill River (Wetlands TWB-05.1 through TWB-01).

Biomap Core Habitats

Similar to the Stoughton Alternative the Whittenton Alternative would cross Biomap Core Habitat in two areas. The Hockomock Swamp, from Foundry Street in Easton south to Bridge Street in Raynham, is designated as Core Habitat.

Living Waters

No mapped Living Waters occur along the Whittenton Alternative.

Fisheries Habitat

According to the Massachusetts Department of Fish and Wildlife comment letter on the DEIS/DEIR, fisheries surveys of the Mill River yielded ten species, including American eel, black crappie, bluegill, brown bullhead, chain pickerel, common shiner, largemouth bass, pumpkinseed, redfin pickerel and tessellated darter.

Breeding Bird Diversity

Potential breeding birds along the Whittenton Alternative are similar to Stoughton Alternative (including the Southern Triangle) as detailed above.

Vernal Pools

A total of 17 vernal pools lie within 750 feet of the right-of-way along the Whittenton Branch and Attleboro Secondary (Table 4.14-9). Much of the Attleboro Secondary is in developed areas of Taunton, and no vernal pools are present in these developed areas.

Table 4.14-9 Summary of Vernal Pools–Whittenton Alternative

Municipality	Pools within ROW	Pools within 100 of ROW (additional)	Pools within 750 feet of ROW (additional)
Canton	0	0	1
Stoughton	1	2	2
Easton	11	20	14
Raynham	0	5	11
Taunton	1	8	18
Berkley	0	4	8
Lakeville	0	1	2
Freetown	4	3	7
New Bedford	0	1	6
Fall River	0	0	0
Total	17	43	71

A total of 136 vernal pools lie along or within 750 feet of the right-of-way of the Whittenton Alternative as a whole.

Similar to the Stoughton Alternative, the Whittenton Alternative passes several large vernal pool complexes, consisting mostly of PVPs. Vernal pools are present on both sides of the right-of-way in Easton, immediately south of the proposed North Easton Station site (Figure 4.14-5b). Movement of

vernal pool amphibians between pools in this area may occur to some degree, but this movement is likely to be constrained by the presence of the existing tracks. A large vernal pool complex is present in Easton south of Foundry Street, extending to the powerline corridor (Figure 4.14-5c). Several discrete vernal pools are present south of the powerline corridor. Large areas of the Hockomock Swamp support breeding of vernal pool amphibians and spotted turtles although they do not meet the regulatory definition of vernal pools. Movement between these areas is currently unrestricted. These sections of the out-of-service right-of-way are heavily used by All Terrain Vehicles (ATVs), which drive through the vernal pools and adversely affect the habitat. A group of PVPs is mapped within the Hockomock Swamp ACEC in Raynham, north of Bridge Street (Figure 4.14-5d). The right-of-way in this area is open and unvegetated, but does not have tracks or ties. This alternative avoids potential impacts to vernal pool complexes present along both sides of the right-of-way south of Pine Swamp in Raynham between East Brittania Street and Thrasher Street, and between Thrasher Street and Winter Street (Figure 4.14-5e).

The New Bedford Main Line and Fall River Secondary pass by relatively few vernal pools, and the pools along these lines do not form clusters. Connectivity between these pools is often already fragmented by existing roads.

Fish and Wildlife Crossings

A detailed inventory of bridges and culverts was conducted to identify the location, condition, and function of each structure. Dimensions, construction materials, and railroad bed characteristics were recorded. For this biodiversity assessment, the subset of bridges and culverts with potential ecological value was determined by reviewing wetland mapping, surrounding land use (as visible in aerial photographs), and other ecological setting features (as modeled by CAPS) of the complete bridge and culvert inventory. The CAPS model output indicates areas with a high (over 50 percent) Index of Ecological Integrity (IEI). No areas with a high IEI exist along the Whittenton Branch.

There are eight structures (one bridge and seven culverts) along the Whittenton Branch that may have biodiversity value by connecting ecosystems, which can allow fish and wildlife to pass from one side of the tracks to the other. Most of these structures also have a hydrologic function, allowing water to flow under or through the railroad structure (subgrade, ballast, ties, and tracks). Bridges that convey roads under or over the railroad bed would also be improved for the project but do not have an ecological function connecting ecosystems and are therefore not included in this biodiversity evaluation.

The culverts along the Whittenton Branch are open- or closed-bottom box or pipe structures beneath the tracks, covered with a layer of railroad bed ballast. Most of the culverts along the alignment are stone boxes; one culvert consists of a clay pipe. The culverts considered in this biodiversity evaluation provide a variety of hydrologic functions, as indicated in Table 4.14-10. Culverts providing upland drainage accommodate stormwater flow but are otherwise dry. Wetland equalization functions maintain surface water levels in adjoining wetlands. Intermittent or perennial streams are conveyed by some culverts. Figures 4.14-14a-b depict existing bridge and culvert locations.

Table 4.14-10 Existing Conditions along the Whittenton Branch–Fish and Wildlife Passage

Wetland ID	Municipality	Description	Function
RWB-02.1, RWB-02	Raynham	Stone box culvert under ROW, 4 feet wide by 5 feet high, intermittent stream likely flows east to west	Carries intermittent stream flow
TWB-10, TWB-09	Taunton	Stone box culvert under ROW, 2.5 feet wide by 3 feet high, intermittent stream likely flows east to west	Limited ecological functions – collapsed/sunken at western end
TWB-08, TWB-07	Taunton	Stone box culvert under Whittenton St., 2.5 feet wide by 3 feet high, intermittent stream likely flows north to south	Carries intermittent stream flow
TWB-07, TWB-06	Taunton	Bridge (approx. 50 feet) over Mill River (perennial), flows west to east	Perennial stream flows under bridge
TWB-06, TWB-05.1	Taunton	Stone box culvert under Warren St., 4 feet wide by 3 feet high, intermittent stream flows south to north	Wetland equalizer
TWB-05.1, TWB-05	Taunton	Stone box culvert under ROW, 2 feet wide by 2.5 feet high at west end, 5 feet wide by 2.5 feet high at east end, intermittent stream flows west to east	Wetland equalizer
TWB-05, TWB-04	Taunton	Stone box culvert under ROW, 3.5 feet wide by 2 feet high at west end, 2 feet wide by 1.5 feet high at east end, intermittent stream flows east to west	Wetland equalizer
TWB-02, TWB-01	Taunton	12-inch diameter clay pipe culvert under ROW, intermittent stream likely flows east to west	Wetland equalizer
TOTAL CROSSINGS: 8			

Other Important Habitat Areas

The Whittenton Branch (Whittenton Alternative), crosses and is adjacent to large wetland and upland areas in Raynham between Route 138 and King Philip Street, and in Taunton adjacent to Prospect Hill Pond, and between Meadow Street and Whittenton Junction (Figure 4.14-6a). These wetlands and wooded upland areas are mostly unfragmented open space that could be important wildlife habitat because they may be used for dispersal, migration, breeding, foraging, and as bird stopover areas.

Stations

This section describes the areas of important biodiversity value within the proposed station sites. None of the proposed station sites are within mapped areas of BioMap Core Habitat, areas of important biodiversity value, or within large areas of undeveloped land. All of the proposed station sites are within fully or partially developed areas.

The station sites that are within fully developed areas and do not contain potential habitat include:

King's Highway—The station would be located in northern New Bedford south of King's Highway, immediately east of Route 140. This station would occupy part of a site that is an existing shopping plaza.

Whale's Tooth—The station would be located on Acushnet Avenue at the existing Whale's Tooth parking lot, which was constructed by the City of New Bedford in anticipation of the commuter rail project.

Fall River Depot—The station would be located 1 mile north of downtown Fall River at Route 79 and Davol Street at the site of the former train station.

Battleship Cove—The station would be located behind the Ponta Delgada monument along Water Street in Fall River. The City of Fall River constructed the Ponta Delgada monument, which includes a pick-up/drop off loop road, in anticipation that this site would be utilized as a commuter rail station.

Easton Village—This station would be located immediately south of the historic H.H. Richardson train station along Sullivan Street in Easton. The existing Historical Society building contains a small parking facility that would be partially reconfigured for pick-up/drop-off traffic flow through the lot.

Raynham Park—The station would be located adjacent to the former Raynham-Taunton Greyhound Park off of Route 138, which is currently operated as a simulcast betting location.

Dana Street (Whittenton Alternative only)—The Dana Street Station would be located just south of the Danforth Street grade crossing, within walking distance of downtown Taunton. The site is a currently vacant lot.

Taunton (Stoughton Alternative only)—The Taunton Station would be located along Arlington Street near Dean Street (Route 44), adjacent to the historic Old Colony train station. The City of Taunton has begun the process of remediating this brownfield site in anticipation of a future train station.

Canton Center—Canton Center Station is an existing station site off of Washington Street that would be modified to accommodate a second track. Two new 800 foot long low-level platforms with mini-high platforms would be constructed (one adjacent to each track). Modifications to the tracks and platforms would require minor changes to the parking layout in the existing lots near the station

Stoughton—The existing Stoughton Station would be relocated to accommodate a second track. The station would be shifted from its present location between Porter and Wyman streets to a new location south of the Wyman Street at-grade crossing. Two new 800 foot long, full-length high-level platforms would be constructed (one adjacent to each track).

With a focus on potential biodiversity, the following sections describe the proposed station sites that are within partially undeveloped areas and may require construction in naturally vegetated areas.

Freetown—The Freetown station site is located on South Main Street and would serve all of the rail alternatives. The approximately 18-acre site is currently in industrial use and is partially occupied by a self-storage facility. The area adjacent to the proposed site is mainly forested and undeveloped and contains areas of wetland habitat. The site is near the western end of the Freetown-Fall River State Forest/Bioreserve. There are additional industrial parcels located north and south of the site. The potential of the site to support biodiversity is limited because it is surrounded by developed areas. No certified or potential vernal pools have been identified near the site (Figure 4.14-4b).

North Easton—The North Easton station site is located at the rear of the Roche Brothers plaza and would serve the Stoughton and Whittenton Alternatives. The proposed site is located just off Route 138 in Easton and would be within the undeveloped portion of the commercial parcel. This portion of the site contains areas of wetland habitat and is near a cluster of certified and potential vernal pools. Land uses on adjacent parcels are commercial, residential, and agricultural. The potential of the site to

support biodiversity is limited because, although open space is located across the tracks, the remainder of the surrounding area is developed (Figure 4.14-5b).

Taunton Depot—The Taunton Depot station site is located at the rear of Target Plaza and would serve the Stoughton and Whittenton Alternatives. The proposed site is currently undeveloped and contains areas of wetland habitat. Adjacent land uses include commercial and residential parcels immediately east and west of the site. The potential of the site to support biodiversity is limited because it is currently surrounded by developed areas. A large wetland complex and two potential vernal pools that have been identified near the station site (Figure 4.14-3a).

Layover Facilities

None of the proposed layover facilities are located within a Priority or Estimated Habitat polygon (see Figures 4.14-3e and 4.14-4b).

4.14.2.3 Summary of Existing Conditions

The study area is the portion of the South Coast region that is adjacent to or crossed by the Build Alternatives. The study area is within the ecoregion called “Bristol Lowland/Narragansett Lowland,” which is defined as a region that has flat gently rolling plains, the forests are mostly central hardwoods, and there are numerous wetlands, cranberry bogs, and rivers that drain this area.[22]

Within the study area, there are several areas of important biodiversity value that are mapped by NHESP as Core Habitat. These include:

- Assonet Cedar Swamp (adjacent to and crossed by the New Bedford Main Line)
- Acushnet Cedar Swamp (adjacent to the New Bedford Main Line)
- Freetown-Fall River State Forest /Southeastern Massachusetts Bioreserve (adjacent to the Fall River Secondary)
- Forge Pond (adjacent to and crossed on a bridge by the Fall River Secondary)
- Hockomock Swamp ACEC (crossed by the Stoughton Alternative)
- Pine Swamp (crossed by the Stoughton Line (Electric and Diesel)

The New Bedford Main Line and Stoughton Line are adjacent to Living Waters Core Habitats. All the alternatives cross important fisheries habitat. Except for the Fall River Secondary, all segments of the alternatives cross and/or are adjacent to large wetlands and/or wooded upland areas. In some instances, these areas include public or privately owned lands under conservation management. These adjacent unfragmented open space areas could be important wildlife habitat because they may be used for wildlife dispersal, migration, breeding, foraging, and as bird stopover areas.

[22] U.S. Environmental Protection Agency (EPA),Ecoregions of Massachusetts, Connecticut, and Rhode Island. Website accessed January 2009. (http://www.epa.gov/wed/pages/ecoregions/mactri_eco.htm).

There are no proposed station sites within BioMap Core Habitat, areas of important biodiversity value, or within large undeveloped areas. All the proposed station sites are within partially or entirely developed areas.

Both of the proposed layover sites (Weaver's Cove East, Wamsutta) have been previously developed for industrial and other uses but have pockets of undeveloped land with limited potential to support biodiversity, depending on site conditions.

Both certified and potential vernal pools are found adjacent to each rail alternative. Several clusters of vernal pools are mapped in the vicinity of each rail alternative. The largest numbers of these occur along the Stoughton Alternative routes.

Table 4.14-11 provides a summary of existing conditions and compares the different alternatives.

Table 4.14-11 Summary of Biological Resources Adjacent to Project Alternatives

Project Alternative (segments)	BioMap Core Habitat	Living Water	Vernal Pools[1]	Important Fisheries Habitat (named Rivers/ streams)[2]	Location
Stoughton Alternative Stoughton Line (Electric and Diesel) Including Southern Triangle	5	2	252	7 (Beaver Brook, Whitman Brook, Queset Brook, Black Brook, Pine Swamp Brook, Taunton River Mill River)	Hockomock Swamp ACEC/ Hockomock Swamp WMA, Pine Swamp, Stoughton Memorial Conservation Land, and other areas of unfragmented habitat.
Whittenton Alternative Stoughton Line (Electric and Diesel) Including Southern Triangle	5	2	203	7 (Beaver Brook, Whitman Brook, Queset Brook, Black Brook, Pine Swamp Brook, Taunton River Mill River)	Hockomock Swamp ACEC/ Hockomock Swamp WMA, Pine Swamp, Stoughton Memorial Conservation Land, and other areas of unfragmented habitat. Tributary to Mill River, Prospect Hill Pond and other areas of unfragmented habitat.

1 Vernal pool numbers were calculated based on MassGIS data for vernal pools found within 750 feet of the right-of-way; and includes certified, potential and other field verified vernal pools

4.14.3 Analysis of Impacts and Mitigation

4.14.3.1 Impact Assessment Methodology

The proposed South Coast Rail alternatives and associated stations are expected to have direct and indirect effects on natural communities and populations of fish, wildlife and plants. This section discusses direct and indirect effects in general, and describes the methodology used to calculate and evaluate impacts to biodiversity within the project study area. The Secretary's Certificate on the ENF identified the need for (1) an evaluation of direct and indirect environmental impacts on wildlife and their habitats including but not limited to: hydrological changes; fragmentation of habitat and populations; edge effects; noise and vibration; and restrictions to wildlife mobility, and (2) an evaluation

of impacts to migratory birds and their habitats, including Important Bird Areas and Blue Heron nesting sites.

Method for Assessing Direct Impacts

Direct impacts of the alternatives would result from constructing the rail, or station elements. For the rail elements that include active freight railroad, construction includes removing vegetation, grading to widen or adjust the profile of the rail, removing and replacing ballast, track and ties, replacing culverts, and restoring bridges. Both rail alternatives utilize active freight lines with ballasted right-of-way, tracks, and ties. There are culverts that convey streams underneath the embankment. The existing culverts under the berm maintain wetland hydrology and provide crossing points for migratory wildlife to access wetland areas on either side of the embankment. The right-of-way itself does not provide suitable habitat wildlife and the tracks and ties prevent turtles, amphibians, and small mammals from moving across the right-of-way except through the culverts.

Station construction would include clearing vegetation, grading, and paving. In both cases, impacts to biodiversity would occur along the edges of natural habitats and would largely be limited to the loss of narrow strips of habitat along existing edges and would not result in fragmentation.

Constructing railroad infrastructure along abandoned railroad corridors could result in different types of direct or indirect impacts. This construction could result in more substantial loss of habitat, fragment large habitat blocks, and create barriers to animal movement, particularly where old rails have been removed and thus no such barriers currently exist.

The direct effects of these actions include the loss of wildlife habitat and plant communities. Actual habitat loss is a direct effect of transportation projects. Habitat loss occurs if an area that previously provided food, cover, water, and/or breeding resources to a species is cleared, paved, filled or altered in such a way that it no longer provides one or more of these resources. These effects were quantified by overlaying the limit of work for each alternative onto the vegetation cover type mapping provided by MassGIS and described in Section 4.14.2.

Direct effects to vernal pools, a specific category of wildlife habitat that receives special attention under wetland protection regulations, were quantified as the loss of wetland containing a vernal pool. Amphibians that breed in vernal pools use upland forested areas as non-breeding habitat. Therefore, consistent with USACE policy,[23,24] the loss of upland forest within 750 feet of a vernal pool was also quantified as the loss of upland habitat for these organisms. To provide a context for evaluating the numerical loss of upland habitat, the area lost was calculated as a percentage of the total upland area within 750 feet of the affected vernal pools.

Areas within permanent alteration limits that are previously disturbed, such as ballasted railbed and roads, were not counted as habitat loss. In addition, impact areas less than 10 feet wide were not counted as habitat loss.

[24] Massachusetts Division of Fisheries and Wildlife. 2009. Natural Heritage and Endangered Species Program's Guidelines for the Certification of Vernal Pool Habitat. MA Div. Fish. & Wildlife, Westborough, MA.

Types of Indirect Impacts

Indirect impacts are defined as the consequences of an action's direct impacts. These are generally not quantifiable, and may occur over a larger area or over a longer time than the direct impacts. Indirect effects change the quality or functions of a resource. They are measured qualitatively and, therefore, are more difficult to accurately assess than direct effects. Indirect effects will generally be described qualitatively for each of the alternatives.

Indirect effects may include habitat fragmentation and associated edge effects; the loss of genetic diversity of plant and animal populations; increased competition for resource, and physical or psychological restrictions on movements caused by some feature within a corridor that wildlife are unwilling or unable to cross. Short-term temporary indirect effects can be caused by the increased noise and visual disturbance from land-clearing, earth-moving, and construction machinery during construction. Following construction, noise associated with an active rail line may cause indirect effects if noise levels are of sufficient magnitude that wildlife avoid habitat near the facility.

Fragmentation is defined as the subdivision of once large and continuous tracts of habitat into smaller patches. It results from agriculture, urbanization, and transportation or other rights-of-way).[25] Habitat fragmentation is associated with 'edge effects' when there is a disturbed or developed area created adjacent to a natural and/or forested area. Edge effects may include the spread of invasive species, increase in the canopy gap and a decrease in species dependent on core and/or undisturbed habitat. In general, fragmentation of habitat is viewed as detrimental when considering original native, climax species composition and abundance, natural history, and relative ecological stability of unmanaged plant and animal populations. In particular, habitat fragmentation increases the amount of edge relative to the amount of interior habitat.[26] Scientific experts agree that preservation of continuous forest blocks is essential to the long-term protection of biodiversity. However, there is considerable controversy among the scientific community as to what are the critical dimensions of 'unfragmented' forests needed to sufficiently protect wildlife habitat and biodiversity.

A railroad may act as a barrier that interferes with the movement of some mammals, amphibians, birds and reptiles from one habitat to another. The width of a railroad corridor can influence the frequency of wildlife crossings, as well as the mortality associated with potential collisions with rail or vehicular traffic. The rail itself on which the tracks are laid can create a barrier to smaller species such as amphibians, reptiles, and smaller mammals. Traffic density and traffic speed may also influence wildlife avoidance of transportation corridors. [27, 28, 29,30]

A potential indirect effect is the introduction of non-native invasive plant species along the linear corridors of disturbed land.

Impacts on Vegetation Community Composition Due to Changes in Physical Parameters of Light and Temperature

Removal of the forest canopy on the existing or proposed railbed could potentially alter the physical conditions (light, wind, temperature) in adjacent forested areas. No adverse effects are anticipated to herbaceous or shrub-dominated communities, since there would be no change in the light, wind or temperature regimes. The canopy gap for the rail alternatives would vary with the width of the limit of work and adjacent land uses. In locations where single track sections are proposed (much of the Southern Triangle, sections of the Stoughton Line and along the Whittenton Branch), the canopy gap would vary between approximately 40 to 80 feet wide. In locations where double track sections are proposed, the canopy gap would vary between 60 to 100 feet wide. Because the project corridors are predominantly oriented along a north-south axis, the resulting forest edges will primarily face east and west.

A review of the relevant scientific literature indicates that incident radiation (direct sunlight) within the understory is a primary factor in determining microclimate in forest ecosystems. Incident radiation within a forest ecosystem is a function of the density of tree canopy and the cumulative amount of projected leaf area. Increases in ambient light levels have been correlated with higher near-ground temperatures, higher vapor pressure deficit and drying of leaf litter.

Recent field studies investigating the edge effects generated by clearcuts have attempted to quantify the increase in light intensity within forests. One study[31] examined forest edge sites in eastern deciduous forests and found strong edge effects associated with increases in light intensity in south, east and west facing forest edges. No statistically significant light intensity edge effects were observed in north facing cuts. Edge effects observed included increases in ambient temperature and vapor pressure deficit and decreases in soil and litter moisture.

The increased light zone extended from 33 feet (10 meters) in east and west facing cuts and up to 115 feet (35 meters) in south facing cuts. These distances are greater than previously published estimates for northern temperate forests. The study examined forest edges associated with wide clearcuts such as fields. Where the proposed rail will require the clearing of a corridor through a forested area, the potential increase in ambient light levels in the understory canopy will be reduced by the shape and orientation of the clearing. The relatively narrow canopy gap and its north-south orientation will limit the potential increase in ambient light within the understory area. Accordingly, the impacts associated with the clearing are considerably less than would be expected in most clear cut/forest edge conditions and would be more similar to a north-facing exposed cut. The study found no significant edge microclimate effects in northern facing cuts. The impact analysis conservatively assumes that increased light, wind and temperature are likely to occur within 30 feet of the cleared edge of the right-of-way, based on the research cited above. The most likely potential effect of this physical change would be to increase the growth rates of the shrubs currently growing in this zone, resulting in a denser shrub layer along the edge. Increased drying of the leaf litter, if this effect occurred, may affect recruitment of shrub and herbaceous species by affecting seed germination and seedling establishment. The anticipated effect would be that the existing sweet pepperbush (*Clethra alnifolia*) and greenbrier (*Smilax rotundifolia*) currently found along the edges of the railbed in wetland areas would respond with enhanced growth and fill the edge gap. These species have responded in this way to increased light

[31] Matlack GR. 1993. Microenvironment variation within and among deciduous forest edge sites in the eastern United States. *Biological Conservation* 66: 185–194.

along the edges of the Hockomock Swamp created by Route 138, and in the Assonet Cedar Swamp along the edges of the New Bedford Main Line.

The temporary nature of the alteration reduces the potential impacts associated with the proposed corridor clearing. An increase in sunlight adjacent to the rail corridor will result in an increase in adventitious limb growth and increased development of the shrub layer. “Closed edges” as defined by Matlack are edges of older clear-cuts where adventitious limbs and shrub growth have closed or partially closed the gaps created by clear-cuts. Once this gap in the canopy is closed, measurable differences in light, temperature, humidity, vapor pressure density and soil moisture are no longer observed.

Impacts to Aquatic Communities Due to Discharge of Pollutants or Change in Light/Temperature Regimes

The rail alternatives are not anticipated to generate non-point source discharges of pollutants to surface waters, and therefore are not considered to have an adverse impact on aquatic communities. A complete discussion of water quality issues is presented in Chapter 4.17, *Water Resources*.

Indirect impacts may occur from the reduction in tree canopy over waterbodies. By reducing canopy cover, surface waters may exhibit changes in light and temperature regimes which have the potential to increase the water body’s algal or macrophyte growth, thereby affecting trophic status. However, based upon the existing canopy coverage and trophic status of these areas, impacts are anticipated to be negligible.

Impacts to Community Structure or Composition Due to Changes in Hydrology

The construction of the existing rail lines altered the hydrology of existing wetlands, and the existing rail and roadway embankments and culverts currently play an important role in the hydrology of adjacent wetlands. Altering the dimensions or elevations of culverts could adversely affect the hydrology of upstream wetlands.

Impacts to Community Composition Due to Introduction of Invasive Species

Construction along any active or inactive rail corridor, or constructing a new rail line, may increase the width of the canopy gap over the railbed and would likely require removing existing vegetation on the elevated railbed. This linear gap, extending through natural communities, which include Atlantic white cedar swamp and red maple swamp, may allow invasive exotic plant species to colonize the railbed or areas adjacent to the railbed. This section examines the invasive species that may potentially be introduced, assesses the likelihood and magnitude of the impacts, and proposes monitoring and mitigation measures.

Invasive species may be defined as “alien species whose introduction does or is likely to cause economic or environmental harm” (Federal Executive Order on Invasive Species).[32] The Massachusetts Invasive Plant Advisory Group (MIPAG) defines invasive plants as “non-native species that have spread into native or minimally managed plant systems in Massachusetts. These plants cause economic or environmental harm by developing self-sustaining populations and becoming dominant and/or

[32] Executive Order 13112, 6183 Federal Register 64 (February 8, 1999).

disruptive to those systems.[33] When established in disturbed sites or old fields, these species suppress the natural pattern of plant community succession.

There is a wide range of invasive species known to occur in Massachusetts, occurring in many habitats from ponds and lakes to sand dunes. The primary potential invasive species that could affect wetland edges include:

- *Phragmites australis*, common reed
- *Lythrum salicaria*, purple loosestrife
- *Berberis thunbergii*, Japanese barberry
- *Frangula alnus*, glossy buckthorn
- *Phalaris arundinacea*, reed canary grass
- *Typha angustifolia*; *T. x glauca*, narrow-leaf and hybrid cattail

Other upland species are potential colonizers of the railbed or the forest edges along the railbed, and include:

- *Fallopia japonica*, Japanese knotweed
- *Elaeagnus umbellata*, Autumn olive
- *Celastrus orbiculata*, oriental bittersweet
- *Rosa multiflora*, multiflora rose

Phragmites australis, common reed, is a robust (2 to 5 meters tall) grass believed to be native to North America, but distributed worldwide. The invasive genotype is likely to be a non-native introduction. *Phragmites* spreads by long underground rhizomes that have a very rapid growth rate, and is capable of colonizing large areas and forming monodominant stands that eliminate virtually all native grasses and forbs. Unlike the native species, *Phragmites* provides little wildlife food value, and the tough leaves decompose slowly, which may alter nutrient dynamics of the wetland system. *Phragmites*, although most commonly a species of wetlands, is also found extensively in dry disturbed upland sites such as fill piles, landfills, and gravel areas. *Phragmites* is wind-dispersed. It typically becomes established following disturbance which substantially alters the soil or removes the forest canopy of a wetland, particularly in roadside sites where soil salt contents may be elevated.

Lythrum salicaria, purple loosestrife, is an herbaceous perennial characterized by long showy spikes of magenta flowers. A native of Eurasia, purple loosestrife was introduced into the northeastern US and Canada in the early 1800s. It spreads through wind dispersal of tiny dry seeds (a single stalk may produce as many as 300,000 seeds) and through underground rhizomes. Purple loosestrife may rarely occur in drier wetland-upland transition sites or disturbed uplands such as cultivated fields, but is

[33] Massachusetts Invasive Plant Advisory Group. 2005. The Evaluation of Non-Native Plant Species for Invasiveness in Massachusetts.

typically a plant of wetland wet meadows and marshes. It generally becomes established following disturbance which exposes the soil surface and may remove native species, but may also invade natural undisturbed wetland communities. Once established, it forms monodominant stands which replace the more diverse native community. Purple loosestrife provides little wildlife habitat or food value.

Berberis thunbergii, Japanese barberry, is a thorny shrub with small leaves and attractive bright-red berries. It was introduced into the northeastern U.S. as an ornamental, and continues to be a popular landscaping shrub. It is dispersed by birds. Japanese barberry has become an aggressive invader of forested wetlands south of Massachusetts (Pennsylvania, New Jersey, Connecticut), and is occasionally found in Massachusetts wetlands. Once introduced, it forms a dense nearly monodominant shrub layer less than 1 meter high that eliminates the native shrubs and herbaceous species. This species appears to be able to colonize natural undisturbed wetland communities.

Frangula alnus, glossy buckthorn, is a tall shrub native to Eurasia. It produces small dark berries, and is dispersed by birds. This species typically invades old fields and pastures, and is a major threat to native prairie ecosystems in the Midwest. In New England, it invades native upland forest and wet meadow swamp communities (although generally not forested wetlands with saturated or seasonally inundated soils), particularly along edges where fruit-eating birds may perch. It is a habitat concern due to its ability to outcompete native shrub species, and because its open branching habit provides poor nesting habitat for songbirds.

Fallopia japonica, Japanese knotweed, is a large (1 to 3 meters tall) herbaceous perennial with large heart-shaped leaves and jointed, bamboo-like stems. It was introduced from England as a garden ornamental in the late 1800s. Japanese knotweed's small seeds are not easily dispersed by either wind or birds, and it does not spread or colonize new sites aggressively. Once established, it spreads by underground rhizomes that form extremely dense patches. No other species grow in the dense shade under the large leaves of Japanese knotweed. This species occurs in open disturbed sites, typically the edges of roads or old fields. It does not grow in the shaded forest understory.

Elaeagnus umbellata, autumn olive, is a shrub with distinctive silvery leaves and fragrant flowers. It has a very dense branching habit, and tends to form monodominant patches in dry disturbed sites. This species was widely planted in the 1950s through 1970s for wildlife habitat, and was recommended by the Soil Conservation Service. The bright red berries are bird-dispersed. This species spreads only by seed, and does not colonize or survive in forested sites or wetlands.

Celastrus orbiculata**,** oriental bittersweet, is a deciduous twining vine that may reach 6 inches or more in diameter. The plant was introduced in the mid-1800s, and currently is found from Maine to Georgia. Bittersweet produces attractive fruits with bright orange fleshy seeds in a yellow leathery capsule. Seeds are bird-dispersed. The vine also spreads aggressively through underground rhizomes. Oriental bittersweet can overrun natural vegetation, overtopping trees and shrubs to form pure stands. The vines can weaken trees by weighting the crown, making it more susceptible to wind and ice damage. Bittersweet tends to become established in open areas such as roadsides or old fields, but, once established, can spread into undisturbed forests. It may occur in the wetland-upland transition zone, but does not occur in the saturated soils typical of wetlands.

Rosa multiflora, multiflora rose, is a perennial shrub with distinctive clusters of small white flowers. It was introduced from Asia in the 1880s as an ornamental, and subsequently was widely planted for wildlife food and cover. Multiflora rose has also been planted along highway medians to reduce

headlight glare and provide a barrier to vehicles. Like other berry-producing shrubs, multiflora rose is dispersed by birds (particularly robins and mockingbirds). It invades old fields, pastures, and roadsides, typically in upland sites that are not excessively well-drained (i.e., more mesic sites than autumn olive), and forms very dense monodominant stands that eliminate native shrubs and herbaceous species. Although *Rosa multiflora* may occur in wet meadows, it does not occur in wetland habitats where soils are saturated or seasonally inundated.

Phalaris arundinacea, reed canary-grass, is a perennial grass that grows 1.6 to 6.5 feet tall. It is native to North America as well as Europe. Since it is native to the United States, it may have been present in the northern parts of New England all along. However, European cultivars were introduced in the early 1800 as forage grasses, and are still used for hay. Reed canary-grass readily spreads via rhizomes and can form dense monocultures that does not allow for native species to readily coexist with it. It has little value for wildlife, and can be too dense to serve as cover for waterfowl and small mammals.

Typha angustifolia; T. x glauca, narrow-leaf and hybrid cattail are perennial aquatic plants that can grow up to 9 feet and are generally found in wet areas. Narrow-leaf cattail is considered by some as an invasive species due to its rapid spreading range and ability to form dense monocultures monospecific stands that replace native plants. While *Typha latifolia* is a common native plant, narrow-leaf cattail is believed to have been introduced into North America from ballast of European ships. Hybrid cattail is thought to be sterile (not likely to produce seed) however form large stands by means of vegetative reproduction.

Upland edges in forested habitats may be potentially colonized by invasive species dispersed by birds (primarily the fruit-eating bird species such as American robin, Northern mockingbird, European starling and cedar waxwing) that perch in the trees along the edge of the right-of-way. This creates the potential for establishment of glossy buckthorn, Japanese barberry, multiflora rose, oriental bittersweet or autumn olive on or along the edges of the right-of-way. Common reed seeds could be blow in by wind gusts, although increased wind is unlikely due to the narrow canopy opening.

Any common reed, multiflora rose, autumn olive and Japanese knotweed would be confined to the open habitat of the right-of-way, and would not be anticipated to invade the forested wetlands. Oriental bittersweet would also not invade the forested wetlands, but has the potential to increase the canopy gap by damaging trees along the edge of the right-of-way. Glossy buckthorn and Japanese barberry, if established, could potentially invade the adjacent forested wetlands, although the saturated and seasonally flooded soils that may be found on the sides of right-of way would reduce the potential for successful establishment or spread except on hummocks.

Impacts to Avian Communities Due to Fragmentation and Edge Effects

Fragmentation of forested tracts has been cited as a major cause in the decline of bird communities, particularly neotropical migrant songbirds (NTMs). Scientific studies generally support the positive correlation between size of a forest and reproductive success of NTMs, and that minimum threshold levels are necessary to maintain successful breeding populations. NTMs appear to be especially susceptible to fragmentation and other indirect effects because they generally have fewer offspring than other birds, and certain behavioral adaptations such as ground-nesting increase their vulnerability to predators and brood parasites.

Fragmentation occurs at several spatial scales, from local, which includes edge effects, to landscape, which encompasses differences in size and shape of forest tracts, to regional, where differences in

canopy cover are studied to determine the effects on breeding birds.[34] The majority of the available literature has focused on large-scale fragmentation that breaks existing forest blocks into disconnected remnants across a landscape by major roadways, residential subdivisions, and clear cuts. Most studies do not define a forest fragment unless it is separated from another forest patch by 300 feet of open land.[35]

Scientific literature provides some information on the size of forests needed to support populations of NTMs. These studies document a positive correlation between the presence and abundance of NTMs, their reproductive success, and the size of a forest block.[36,37,38,39,40] The "core" or interior area necessary to maintain successfully reproducing populations varies widely, depending on the species context. In landscape studies, NTMs have been found to require areas at least 250 acres to maintain successful reproductive populations.[41,42] In general, smaller isolated forest blocks are thought to be "sinks" where local populations are likely to undergo frequent extinction and recolonization, and larger forest blocks are thought to be "sources" which maintain stable populations and from which birds disperse to colonize smaller sites.[43,44]

Some birds that breed in the Hockomock Swamp, such as brown creeper, ovenbird, and northern waterthrush, require large, unbroken tracts of forest to maintain successful populations. Such species are considered "area-sensitive" and may be more susceptible to edge effects and other indirect results of forest fragmentation than more disturbance-tolerant species. Forest areas that are less than 12 to 25 acres do not support area-sensitive, forest-nesting NTMs.[45,46,47] The available studies indicate that forest blocks smaller than 60 acres may contain nesting NTMs, but that reproductive success is limited and species diversity is low. These should be considered "small."[48, 49]

49 Villard, M., P.R. Martin and C.G. Drummond. 1993. Habitat fragmentation and pairing success in the ovenbird *(Seiurus aurocapillus). Auk* 110(4) pp. 759-768.

Studies indicate that moderately-sized forest blocks averaging 125 to 150 acres are likely to support some NTMs, particularly the "common" species such as rose-breasted grosbeak [*Pheucticus ludovicianus*], red-eyed vireo [*Vireo olivaceous*], or eastern peewee, but do not support the less common area-sensitive species such as yellow-throated vireo [*Vireo flavifrons*], hermit thrush [*Catharus guttatus*], or veery.[50, 51] Large forest blocks, which provide sufficient contiguous forest-interior habitat to support successfully reproducing populations of area-sensitive forest-interior nesters such as ovenbird or Louisiana waterthrush [*Seiurus motacilla*], must be over 500 acres.[52] Several studies suggest that 750 to 1,200 acres are necessary, and that even larger areas in excess of 7,500 acres are optimal.[53, 54, 55, 56]

Predation is an indirect effect associated with forest fragmentation, and may increase as opportunist predators such as crows [*Corvus brachyrhynchos*] and raccoons [*Procyon lotor*] move into the edges adjacent to the project alignment. However, the existing active railbeds are open, and the inactive segments (Hockomock Swamp, Pine Swamp, and the Whittenton Branch) are used as trails, so there are likely to be existing predation-related edge effects under existing conditions. Segments adjacent to an open overhead powerline clearing may exhibit similar characteristics. There may also be increased brood-parasitism on songbirds if brown-headed cowbirds (*Molothrus ater*) colonize the edges adjacent to the rail. However, it is unlikely that large numbers of cowbirds will colonize the reconstructed right-of-way because the increase in canopy width is minimal. One study found that brown-headed cowbirds were significantly more abundant along paved secondary road forest edges than along either unpaved roads or powerline corridors.[57] This study also showed that there was no significant reduction in forest-interior nesters where corridors were less than 25 feet wide.

Also, it is possible that the commuter rail will displace some individuals of wildlife populations that are sensitive to noise and vibration, causing increased competition for nearby suitable habitat. Woodland songbirds such as the black-billed cuckoo (*Coccyzus erythropthalmus*) have been shown have lowered reproductive success adjacent to noise sources, where these sources produce continuous high noise levels, possibly due to increased stress hormones, interference with communication during the breeding season, or reduced food supply from noise avoidance of prey.[58] Most of the scientific studies conducted on noise and wildlife involve assessing impacts from roads, and there is limited scientific data for impacts to wildlife from rail. Most studies show that noise associated with high-density roads impacts avian communities by interfering with communication during courtship and brood-rearing. However, the continuous noise resulting from highways is substantially different from the infrequent noise produced by trains. Noise impacts are expected to be minor because of the low numbers of trains and relatively low noise associated with single-welded rail.

Impacts to Reptile or Amphibian Communities Due to Fragmentation

A railroad corridor may act as a barrier that interferes with the movement of amphibians and reptiles from one habitat to another. The width of a railroad corridor can influence the frequency of wildlife crossings, as well as the mortality associated with potential collisions with rail traffic. The railbed on which the tracks are laid can itself create a barrier to smaller species such as amphibians, reptiles, and smaller mammals. Traffic density and traffic speed may also influence wildlife avoidance of transportation corridors.[59, 60, 61, 62] The existing rail and highway rights-of-way currently provide limited habitat for reptiles and amphibians.

Indirect impacts to reptile and amphibian populations could include lowered reproductive success of existing amphibian populations if rail collisions affect amphibian mortality rates. If the rail is experienced as a barrier by migrating amphibians, existing populations may be divided into subpopulations. This, in turn, may result in a reduced gene pool in the remaining subpopulations, which could result in loss of the population if the remaining genetic variation is not diverse enough to offset the joint action of natural selection and genetic drift. Preserving genetic diversity is important because it allows populations the potential to adapt by “saving” genes that may be useful during future environmental changes. However, the rail will not create a complete barrier to movement between the eastern and western sides of the right-of-way.

Indirect Impacts to Vernal Pool Species

Indirect effects change the quality or functions of a resource and can be caused by a number of factors:

- Direct fill to vernal pools, which reduces the size of the pool;
- Impacts to vernal pool habitat (wetland areas within 100 feet of a vernal pool);
- Impacts to immediate upland buffer habitat (naturally vegetated, undeveloped upland areas within 100 feet of a vernal pool);
- Impacts to surrounding upland habitat (naturally vegetated, undeveloped upland areas between 100 and 750 feet from a vernal pool); and
- Habitat fragmentation.

Direct fill to vernal pools can have indirect impacts in addition to the direct impacts discussed in the previous section. By reducing the volume of water that collects in a given pool, fill to portions of a vernal pool may increase the chances that the pool will warm up more quickly during the season and/or dry out completely before species have matured enough to leave the pool. In some cases, early warming can be beneficial by speeding larval growth. However, pools that dry out early have a reduced ability to provide effective breeding habitat.

Filling vernal pool habitat results in losses of wetlands in the vicinity of a given pool; these losses can affect pools in several ways. Losses of wetlands, particularly mature forested wetlands, close to a given pool can reduce the shading over the pool, which contributes to increased warming and drying effects. Loss of wetlands near vernal pools also reduces the amount of leaf litter and detritus that seasonally falls into the pool. Since these detrital inputs form the basis of the food web for the pool, reducing these inputs results in a loss of the pool's overall ability to sustain healthy populations. Loss of wetlands near the pool also reduces the available non-breeding habitat for species that use the pools, and can therefore impact biodiversity in the pool. However, for many "classic" vernal pools that consist only of a confined basin depression, there are no adjacent wetland areas at all, and the entire surrounding area provides upland buffer habitat.

Upland buffer habitat is also a necessary component of a vernal pool ecosystem. This habitat is undeveloped land with natural vegetation that provides upland non-breeding habitat and/or migratory habitat for vernal pool species. Many obligate vertebrate vernal pool species, such as wood frogs and spotted salamanders, spend the majority of a given year in the upland areas near vernal pools, using these areas for foraging, shelter, and overwintering. A loss of upland buffer habitat translates to a loss in the ability of the area to provide a necessary component of the life cycle of these obligate species. Mature forested uplands in particular can provide valuable habitat for species, since treefalls, rotting logs, and heavy leaf cover all provide shelter and foraging opportunities for obligate vernal pool species.

Surrounding upland habitat is important for providing additional foraging, shelter, and overwintering habitat for many obligate vernal pool species. Some species have a lifespan of several years or more, and often these animals will travel several hundreds of feet away from a vernal pool, then return to the same pool or cluster of pools each spring to breed. Surrounding upland habitat thus maintains a healthy species density and distribution.

The effects of habitat fragmentation can create additional indirect impacts on vernal pools and the species that use the pools. Habitat fragmentation is of particular concern where the rail line has been abandoned and only portions of the original berm exist. In these cases, construction of new tracks and widening of existing berms as a result of the project would create additional barriers to movement. The project would create a barrier to wildlife movement through portions of the Hockomock Swamp area (north of the proposed trestle and south of Raynham Park station) and through the entire Pine Swamp. This barrier effect is likely to fragment populations of vernal pool amphibians that are unable to cross the railroad tracks. Areas with existing tracks (whether active or not and especially those on top of steep embankments), are likely to provide some current barrier to movement, although some movement across existing rail lines can occur through gaps and openings under rails and between rail ties. Constructing the railroad would create more areas of steep slopes, wider portions of ballast, an expanded railroad bed from single track to multiple tracks, and new retaining walls in many locations, all of which would increase the effects of habitat fragmentation on vernal pool amphibians.

Impacts to Mammalian Communities Due to Fragmentation

Direct impacts include collisions between mammals and trains. Indirect impacts from fragmentation include potentially lowered reproductive success rates from interruption of migration routes to breeding areas (restricted gene flow), increased predation on small mammals due to lack of cover on the ballasted railroad embankment, and general disturbance of mammalian communities immediately adjacent to the right-of-way. These disturbances include alterations to foraging, denning and overwintering habitat due to changes in vegetative cover and light and temperature regimes.

There may be minor indirect impacts to small mammals but this is not expected to affect population stability because of their small home ranges. Deer are expected to continue to cross the tracks with minimal impedance.

Impacts to Wildlife from Noise

The study of noise and its effects on wildlife, or acoustic ecology, began in the 1970s, and several papers have been published documenting the effects of noise on wildlife populations. However, most of the research to date has been on noise generated from aircraft and sonic booms, with few studies on vehicle and rail traffic. Studies have also focused more on laboratory animals than wildlife because of the logistical difficulties and costs associated with evaluating noise effects in the wild. Comments on the DEIS/DEIR asked the applicant to provide additional information on the effects of noise on wildlife specific to the habitat surrounding the alternatives and reference scientific literature as appropriate.

There is currently no accepted method of measuring the effects of noise on wildlife. Most of the research to date indicates that the sound exposure level (SEL) provides the most useful predictor in noise effects. Because wildlife differ in their sensitivities to noise from humans, and amongst other species, (*e.g.,* bats are sensitive to a greater sound frequency than humans, while bullfrogs have a much lower detection range), an A-weighted scale was devised. The A-weighted scale interprets the sound based on the loudness perceived by the listener.

Noise can induce physiological and behavioral responses in animals. Effects are most often noted when the noise source is brief in duration and in excess of 100 dB.[63,64] Physiological stress can include higher adrenal weights and ascorbic acid levels, and increased cortisol levels, which play a role in the stress reaction. Prolonged exposure to loud, abrupt noise (such as sonic booms) may decrease the life expectancy, induce weight loss, and lower reproductive success of animals that cannot move away from the noise source. Prolonged exposure to very high noise levels may also result in loss of hearing for animals that are unable to relocate from the noise source.

Behavioral responses of wildlife to noise are somewhat easier to document in the field. Noise may result in masking, which is the inability of animals to communicate effectively. This may have effects on reduced breeding success for courting birds that are unable to advertise territories or secure mates, lowered prey captures for species that depend on auditory cues to locate food, increased mortality for species that rely on hearing predators approach in order to escape, or increased mortality associated with winter-stressed animals attempting to escape a perceived threat.

Some wildlife species habituate to noise. Upland sandpipers (*Bartramia longicauda*), a state-listed species, are most frequently found nesting in airfields and adjacent open spaces in the northeast. Research has shown that some species, such as terns, caribou, and grizzly (none of which have been documented to occur within the study area), do not habituate but continue to experience each noise event as a stressor.

[64] Bradley, F., C. Book, and A.E. Bowles. 1990. Effects of low-altitude aircraft overflights on domestic turkey poults. Report No. HSD-TR-90-034. US Air Force Systems Command, Noise and Sonic Boom Impact Technology Program.

The loudest noise that the commuter rail will emit is the whistle as it approaches at-grade crossings (105 dB). Under normal operating conditions, the train will produce a noise disturbance of between 80 and 88 dB that is infrequent, short in duration, and is below potential impact thresholds.

Scientific literature and other relevant publications concerning the effects of train pass-by noise on wildlife were reviewed. Many of the available studies are from western states; far less is known about the effects in the eastern United States, presumably because highway and rail infrastructure was largely already in place well in advance of the advent of modern wildlife ecology and conservation biology, and also because of the proportionately larger numbers of endangered mammals long displaced in the east and now confined to the less-developed west. As documented in the National Park Service's Annotated Bibliography – Impacts of Noise on Wildlife,[65] the effects of noise on wildlife have been studied for roads (where noise is continuous), aircraft, boats, and off-road vehicles and snowmobiles. No specific studies on the effects of trains are listed in this bibliography. The FHWA's Highway Traffic Noise website provides an extensive discussion of the impacts of road and highway noise on all classes of wildlife and concludes that different groups of wildlife respond to highway noise in different ways. The FHWA notes that very few studies have directly addressed the impact of noise from roads, and that studies primarily focus on the distribution and abundance of wildlife in areas adjacent to roads. As a result, the effects of noise cannot be separated from the effects of mortality or barriers to movement. The only mention of trains in the FHWA document is this passage: "It has been found that various mammals will avoid roads and (in some cases) this has been attributed to noise… For example, mountain goats would hesitate to cross the road if they heard a truck changing gears over 1 kilometer away. Passing vehicles in this study were perceived as a threat (speed limit 50 mph). Interestingly, the goats did not seem to be disturbed by the noise from trains." The literature review regarding analysis of effects of train pass-by noise on wildlife also included recent Environmental Impact Statements available on the Federal Railroad Administration (FRA) website. This review did not indicate additional information regarding potential impacts or assessment methods beyond those previously described in the DEIS. In absence of additional indirect noise impact assessment methods identified in more recent applicable scientific studies the assessment method for the FEIS remained unchanged from the DEIS.

CAPS Analysis

The University of Massachusetts' Conservation Assessment and Prioritization System (CAPS) model was used as a supplemental method of evaluating indirect impacts to biodiversity. CAPS is a computer software program designed to assess the ecological integrity and biodiversity value of every location based on natural community-specific models, in order to help prioritize lands for conservation action based on their assessed ecological value. It provides a quantitative assessment of ecological integrity that can be used to compare various scenarios. Appendix 4-14-B provides the complete UMass CAPS analysis report for the South Coast Rail project. More information about CAPS can also be found at the University of Massachusetts web site: http://www.umass.edu/landeco/research/caps/caps.html.

About CAPS

As stated in the Conservation Assessment and Prioritization System (CAPS) South Coast Rail Analysis[66]:

[65] National Park Service Annotated Bibliography-Impacts of Noise on Wildlife. Available online at http://www.nature.nps.gov/sound/assets/docs/Wildlife_AnnotatedBiblio_Aug2011.pdf.

[66] Conservation Assessment and Prioritization System (CAPS) South Coast Rail Analysis, B. W. Compton, S. D. Jackson and K. McGarigal, September 18 2009.

"[T]he Conservation Assessment and Prioritization System (CAPS) is an ecosystem-based (coarse-filter) approach for assessing the ecological integrity of lands and waters. We define ecological integrity as the ability of an area to support biodiversity and the ecosystem processes necessary to sustain biodiversity, over the long term. CAPS is a computer software program and an approach to prioritizing land for conservation based on the assessment of various ecological communities (e.g. forest, shrub swamp, headwater stream) within an area. This approach combines principles of landscape ecology and conservation biology with the capacity of modern computers to compile spatial data and characterize landscape patterns.

"The CAPS approach begins with the characterization of both the developed and undeveloped elements of the landscape (Appendix A). With a computer base map depicting various classes of developed and undeveloped land, we then evaluate a variety of landscape-based variables ("metrics"; Appendix C). A metric may, for example, take into account how well a point in the landscape is connected to similar points, the intensity of traffic on nearby roads, or the expected vulnerability to invasions by exotic plants. The results of each metric are rescaled by percentiles for each community so that, for instance, the best 10 percent of marshes have values greater than or equal to 0.90, and the best 25 percent have values greater than or equal to 0.75. This is done to adjust for differences in units of measurement among metrics and to account for differences in the range of metric values for each community. The rescaling by community is done to facilitate identifying the "best" of each community, as opposed to the best overall—which is strongly biased towards the dominant, matrix-forming communities.

"Various metrics are applied to the landscape and then integrated in weighted linear combinations as models for predicting ecological integrity. The rescaled values are weighted using weights determined by expert teams, to reflect the relative importance of each metric for each community (Appendix D), and then added together to compute an overall IEI. Thus, the final index of ecological integrity for each cell is a weighted combination of the metric outputs for that cell, based on the community the cell falls in. This process results in a final Index of Ecological Integrity (IEI) for each point in the landscape based on models constructed separately for each ecological community.

"Because CAPS provides a quantitative assessment of ecological integrity it can be used for comparing various scenarios. In essence, scenario analysis involves running CAPS separately for each scenario, and comparing results to determine the loss (or gain) in IEI units. This scenario testing capability can be used to evaluate and compare the impacts of development projects on habitat conditions as well as the potential benefits of habitat management or environmental restoration. CAPS is an objective and flexible approach for assessing ecological integrity and supporting decision-making for land protection, habitat management, ecological restoration, project review and permitting to protect habitat and biodiversity."

Methods Used for the South Coast Rail Analysis

The CAPS analysis was based on the most recent CAPS statewide run (CAPSma 2009, Conservation Assessment and Prioritization System (CAPS) Preliminary Statewide Massachusetts Assessment, June 2, 2009) with modifications as necessary to more fully represent the effects of railroads.

The geographic scope of the analysis (Figure 4.14-15) includes the entire Taunton River watershed, plus a 5-kilometer (3.2 miles) buffer around the project elements outside of the Taunton River Watershed

(the Northeast Corridor, the Fall River Secondary, and the New Bedford Main Line). This buffer allows CAPS to capture all changes in IEI among scenarios. Using the entire Taunton River Watershed gives CAPS a large enough context to reasonably scale IEI.

CAPS was modified for this analysis to better represent the effects of railroads on biodiversity. The principal effects are barriers to wildlife movement and traffic intensity (which results in noise, disturbance, and mortality). These modifications included:

Several new cover types were added to CAPS to represent rail lines. Rail classes included “abandoned rail with tracks”, “abandoned rail without tracks”, “commuter rail with a trestle”, and “commuter rail with a retaining wall”. Abandoned rail lines represented in CAPS from MassGIS were considered to have no tracks except where they were more accurately represented in the South Coast Rail data.

Numbers of tracks (1, 2, 3) were estimated based on MassGIS data and information from the SCR conceptual design. In general, the SCR scenarios were represented as having two sets of tracks. All rails were assumed to be unfenced, since commuter rails are typically fenced only in developed areas.

The analysis estimated train frequency on each segment as 2 freight trains per day and 33 commuter rail trains. The number of Amtrak passenger trains was determined using the Amtrak schedules. Train length was estimated at 25 cars/train for freight trains, 6 cars/train for commuter rail trains and 8 cars/train for Amtrak passenger trains. The traffic rate parameter was set at one rail car = 20 automobiles except for the trestle alternatives, which used one rail car = 6.7 automobiles to account for a lower “roadkill” mortality.

The parameters of new cover types were developed by an expert team including representatives of The Nature Conservancy, MassAudubon, MassWildlife, and UMass Amherst. The team also developed a new variable (terrestrial barriers) which includes various anthropogenic barriers to wildlife movement. The values assigned to terrestrial barriers ranged from 1 (no barrier, abandoned rail without tracks) to 10 (noise barrier or retaining wall).

The CAPS model was run for each alternative listed below:

- Current (base) scenario
- No-Build Alternative
- Stoughton Alternatives (without a trestle)
- Stoughton Alternatives (with a trestle)
- Whittenton Alternatives (without a trestle)
- Whittenton Alternatives (with a trestle)

The analysis calculated the direct loss of IEI by the complete loss of IEI for affected cells (cells which fell within the stations or new right-of-way). Indirect loss was calculated for each metric, and the integrity model was used to create an overall indirect loss grid for each alternative.

A sensitivity analysis was conducted by varying the relative traffic rate for trains, from 1 rail car = 5 automobiles, to 1 rail car = 100 automobiles. The sensitivity analysis was run for the three metrics that are affected by the intensity of the barrier and by traffic rate: connectedness, similarity, and traffic intensity. The sensitivity analysis, showing the range of expected results given the uncertainty in the effects of train traffic, shows that although traffic rates have a moderate effect on absolute loss in IEI, the ranking of the alternatives does not change under either the high or low traffic scenarios. The sensitivity analysis suggests that the uncertainty in accounting for traffic effects of railroads has only a minor effect on the relative results.

4.14.3.2 Impacts of Alternatives by Element

No-Build (Enhanced Bus) Alternative

The No-Build Alternative would consist of enhancing current bus service along existing roads and highways. The alignments would not change and no new highway construction would be required for the No-Build Alternative. Three existing Park-and-Ride facilities would be re-striped to improved capacity and traffic flow as part of the No-Build Alternative. The three affected Park-and-Ride facilities are:

- The West Bridgewater Park and Ride, located near the southwest corner of the intersection of Routes 106 and 24 in West Bridgewater
- The Mount Pleasant Street Park and Ride, located on the northwest corner of the intersection of King's Highway and Route 140 in New Bedford
- The Silver City Galleria Park and Ride, adjacent to the Silver City Galleria shopping mall in Taunton

Biodiversity would not be adversely affected by this alternative, as there would be no loss of natural habitats and no new habitat fragmentation.

Southern Triangle (Common to All Rail Alternatives)

Portions of the rail lines within the southern part of the South Coast Rail study area are common to all rail alternatives. These rail lines form a rough triangular shape running south from Myricks Junction to Fall River (the Fall River Secondary) and from Weir Junction through Myricks Junction to New Bedford (the New Bedford Main Line), and are therefore referred to as the Southern Triangle. There are no Areas of Critical Environmental Concern (ACECs) within the Southern Triangle. The following sections describe the environmental consequences to biodiversity that may result from each alternative of the South Coast Rail project which is inclusive of the Southern Triangle.

Stoughton Electric Alternative

The Stoughton Electric Alternative includes improvements to existing active freight or commuter rail lines (from Weir Junction to Dean Street, and north of Stoughton Station) and track construction on out-of-service or abandoned rights-of-way (between Dean Street and Stoughton Station as well as the Southern Triangle. It includes constructing a trestle through part of the Hockomock Swamp to reduce impacts to wetlands, biodiversity, and rare species. A section of the out-of-service line crosses land within the Hockomock Swamp ACEC.

Biomap Core Habitats

The Stoughton Alternative would cross Biomap Core Habitat in two areas. The Hockomock Swamp, from Foundry Street in Easton south to Bridge Street in Raynham, is designated as Core Habitat. Pine Swamp in Raynham, from King Philip Street to East Britannia Street, is also a Biomap Core Habitat.

The Stoughton Electric Alternative would create a barrier to wildlife movement through portions of the Hockomock Swamp area (north of the proposed trestle and south of Raynham Park station) and through the entire Pine Swamp. This barrier effect is likely to fragment populations of small vertebrates (e.g. small mammals, reptiles, and amphibians) that are unable to cross the railroad tracks. The portion of the Stoughton Electric Alternative that is a proposed trestle (approximately 8,500 feet long) would not impede wildlife movement.

The Stoughton Electric Alternative would create a new canopy gap through portions of the Hockomock Swamp, primarily from Foundry Street south to the proposed Raynham Park station, where the forest canopy has partially closed over the railbed since the tracks were removed. This canopy gap could impede the movement of forest interior birds across the right-of-way, reducing the effective size of the forest block, and would create new “edge effects” of increased light and temperature, and decreased humidity, adjacent to the right-of-way. The barrier effects of the Stoughton Electric Alternative would extend upward from the tracks as a result of the overhead catenary system. Reconstructing the rail line would create and maintain a canopy gap that varies with the width of the limit of work. This gap would divide the Hockomock swamp south of Foundry Street into two units of approximately 2,293 acres west of the rail line and 505 acres east of the rail. These areas are further divided by the existing powerline corridor, as shown on Figure 4.14-16. On the east side of the MBTA right-of-way there are two blocks divided by the powerline with the northeast quadrant totaling 157 acres and the southeast quadrant totaling 348 acres. On the west side of the MBTA right-of-way, there are two blocks divided by the powerline with the northwest quadrant totaling 84 acres and the southwest quadrant totaling 2,209 acres.

Removing the forest canopy on the railbed within the Hockomock Swamp ACEC study area could potentially alter the physical conditions (light, wind, temperature) in adjacent forested areas. No adverse effects are anticipated to herbaceous or shrub dominated communities, since there would be no change in the light, wind or temperature regimes. The canopy gap is anticipated to be approximately 40 feet in width for the length of the trestle, and the resulting forest edges will face east and west.

During the original construction of the embankment through the Hockomock Swamp in the 1840s, alterations to the hydrology of the Swamp occurred. This is evident in the existing vegetation of the area. Currently, surface water occurs at a slightly higher elevation on the western side of the embankment. Water flows from west to east through all culverts beneath the embankment. This alternative would not include repair or replacement of any culverts. Therefore, there would be no potential changes to hydrology, and no potential impacts to community structure or composition.

Reconstructing the railroad track system through the Hockomock Swamp ACEC would increase the width of the canopy gap over the railbed to approximately 30 feet wide in areas with single track (through the Hockomock and Pine Swamps) and somewhat wider in in areas with double track (north of North Easton Station and a segment south of the trestle near Raynham Park Station), and would require the removal of existing vegetation on the elevated railbed. Canopy clearance requirements will be specified in the Vegetation Management Plan.

This linear gap, extending through natural communities, which include Atlantic white cedar swamp and red maple swamp, may allow invasive plant species to colonize the railbed or areas adjacent to the railbed. This section examines the invasive species that may potentially be introduced, assesses the likelihood and magnitude of the impacts, and identifies monitoring and mitigation measures.

Within the Hockomock Swamp ACEC, common reed has become established in the open, disturbed wetlands within the powerline corridor; and has sparsely penetrated approximately 15 to 20 feet into the adjacent red maple swamp by rhizome growth (although not vigorous, due to dense shade). It is well-established in open wetlands throughout Pine Swamp, particularly under the existing powerline corridor. Glossy buckthorn is sporadically established along the dirt road within the powerline corridor and occasionally on hummocks within the red maple swamp south of the powerline corridor. Autumn olive has not been observed within the study area, but is present on the old ballast between I-495 and Carver Street. Oriental bittersweet is sparsely established along the dirt road within the powerline corridor. Multiflora rose is sparsely established along the dirt road within the powerline corridor; and more abundantly on the old ballast south of I-495.

Any common reed, multiflora rose, autumn olive and Japanese knotweed would be confined to the open habitat of the right-of-way, and would not be anticipated to invade the forested wetlands. Oriental bittersweet would also not invade the forested wetlands, but has the potential to increase the canopy gap by damaging trees along the edge of the right-of-way. Glossy buckthorn and Japanese barberry, if established, could potentially invade the adjacent forested wetlands, although the saturated and seasonally-flooded soils on the west side of the right-of-way would reduce the potential for successful establishment or spread except on hummocks. There is a low likelihood of successful establishment of common reed in the closed-canopy red maple or Atlantic white cedar swamps due to the dense shade and lack of soil disturbance. For these reasons, purple loosestrife is also not anticipated to invade the ACEC swamps. The trestle, since it would minimize earth disturbance and vegetation management along the right-of-way, would be expected to result in less potential for invasive species introductions than at-grade rail construction.

Although the Stoughton Alternative would increase the canopy gap and create a partial barrier to vertebrate movement in areas north, and south, of the proposed trestle, Hockomock Swamp would continue to provide moderate- to large-sized forest blocks. West of the right-of-way, there would be two forest blocks, one north and one south of the powerline corridor. The southern block constitutes the majority of Hockomock Swamp and will provide 2,209 acres of continuous forest. The northern block will continue to provide sufficient size (84 acres) to support all area sensitive species successfully that currently may be present. The eastern segments at 157 acres north of the powerline corridor and 348 acres south of the powerline corridor will likely also continue to provide habitat for area-sensitive NTMs.

Predation is an indirect effect associated with forest fragmentation, and may increase as opportunist predators such as crows and raccoons move into the edges adjacent to the project alignment. However, the existing railbed is open and used as a trail, so there are likely to be predation-related edge effects under existing conditions. Through the Hockomock Swamp, the existing upland berm will not be widened, and therefore the possibility that this will be used as a trail by ground predators is not likely to be any different than under existing conditions.

There may also be increased brood-parasitism on songbirds if brown headed cowbirds colonize the edges adjacent to the rail. However, it is unlikely that large numbers of cowbirds will colonize the reconstructed right-of-way because the increase in canopy gap width is minimal. One study found that

brown headed cowbirds were significantly more abundant along paved secondary road forest edges than along either unpaved roads or powerline corridors. This study also showed that there was no significant reduction in forest interior nesters where corridors were less than 25 feet wide.

The trestle is not expected to have direct effects to reptile or amphibian movements in Hockomock Swamp. The structure will be elevated approximately 5 feet above the existing railroad berm, and therefore will not impede movement across or along the right-of-way. This is not expected to result in loss of nesting habitat because there would be no construction on the existing berm except for pilings, and the habitat characteristics of open sandy soil will not be altered. Minor indirect impacts are anticipated from the trestle. These may include an aversion to using the existing nesting habitat along the rail. However, it is possible that turtles along the MBTA right-of-way will seek other areas to nest.

This alternative would not create a new canopy gap or expand the canopy gap in Pine Swamp, because Taunton Municipal Power and Light which currently owns the former rail right-of-way already maintains a linear clearing in the canopy to accommodate an overhead power line corridor below which the proposed tracks would be located. Pine Swamp consists of approximately 475 acres of forest, bounded by King Philip Street and developed areas to the north and east, Route 138 to the west, and developed areas and Thrasher Street to the south. Based on its size, Pine Swamp likely supports common NTMs, and may support other, more area sensitive species.

Living Waters

The Stoughton Alternative is adjacent to Living Water Core Habitat (LW080) near a reach of the Taunton River that provides habitat for Atlantic sturgeon. As noted in Section 4.15.3.3, the NMFS stated it is unlikely that any species listed under their jurisdiction will be exposed to any direct or indirect effects of the proposed South Coast Rail project. The right-of-way crosses this section of the Taunton River for approximately 125 feet, south of Weir Junction in Taunton (Figure 4.14-3a). North of Weir Junction, the Stoughton Alternative crosses the Taunton River three more times on a series of bridges located upstream from the area mapped as Living Water (LW080) (Figure 4.14-5e). The proposed reconstruction would not have a direct or indirect effect on the ability of the Taunton River to support aquatic biodiversity.

Portions of the Acushnet Cedar Swamp, particularly Turner Pond, are designated as Living Waters. The proposed reconstruction of the New Bedford Main Line would be approximately 7,500 feet west of Turner Pond and would not have a direct or indirect effect on the ability of the pond to support aquatic biodiversity.

Fisheries Habitat

The Stoughton Alternative crosses Whitman Brook, Queset Brook, Black Brook, Pine Swamp Brook, Taunton River, Mill River, Cotley River, Cedar Swamp River, and Fall Brook which are all important fisheries habitats. The proposed alternative would reconstruct existing bridges at Whitman Brook, Queset Brook, Black Brook, Pine Swamp Brook, Cedar Swamp River and the Taunton River, and would construct a new bridge at Black Brook (the former rail bridge was washed out). These bridges would be reconstructed with the same or wider opening, maintaining habitat connectivity and the riverine substrate. The capacity of these waters to support aquatic diversity would not be adversely affected.

Breeding Bird Diversity

This section discusses potential impacts to breeding bird populations within each of the key avian habitat areas.

Hockomock Swamp—The railroad alignment through the Hockomock Swamp, under existing conditions, largely has a closed forest canopy in the segment between Foundry Street and the proposed Raynham Park Station. South of the proposed station, the right-of-way is maintained as an overhead power line corridor and trail used by pedestrians and ATVs. Converting the out-of-service railroad alignment to active rail would not increase or create a new canopy gap, and therefore would not change the existing forest interior conditions. Reconstructing the railroad track system through the Hockomock Swamp will increase the width of the canopy gap over the railbed to 30 feet wide in areas with single track.

Although the Stoughton Alternative would increase the canopy gap and create a partial barrier to vertebrate movement in areas north, and south, of the proposed trestle, the Hockomock Swamp would continue to provide moderate- to large-sized forest blocks. West of the right-of-way, there would be two forest blocks, one north and one south of the powerline corridor. The southern block constitutes the majority of Hockomock Swamp and will provide 2,557 acres of continuous forest. The northern block will continue to provide sufficient size to support all area sensitive species successfully that currently may be present. The eastern segments at 157 acres north of the powerline corridor and 348 acres south of the powerline corridor will likely also continue to provide habitat for area-sensitive NTMs.

Pine Swamp—The railroad alignment through Pine Swamp, under existing conditions, is maintained as an overhead power line corridor and trail used by pedestrians and ATVs. Converting the out-of-service railroad alignment to active rail would not increase or create a new canopy gap, and therefore would not change the existing forest interior conditions. There would be some loss of open shrub vegetation along the powerline, potentially reducing the available breeding habitat for birds such as catbird, common yellowthroat, or song sparrow. However, routine maintenance of the corridor by Taunton Municipal Power and Light already results in frequent and ongoing clearing of shrubs and saplings (and concomitant impacts to bird species) in this area. The re-introduction of trains would have a negligible effect on breeding bird usage.

Assonet Cedar Swamp—The Assonet Cedar Swamp is crossed by active freight rail lines under existing conditions. The reconstruction of the active rail line would not create a new canopy gap, and would therefore not change the existing forest interior or edge conditions. The only change to bird habitat would be increased train passage.

Freetown-Fall River State Forest—The Freetown-Fall River State Forest is crossed by active freight rail lines under existing conditions. The reconstruction of these active rail lines would not create a new canopy gap, and would therefore not change the existing forest interior or edge conditions. The only change to bird habitat would be increased train passage.

Acushnet Cedar Swamp—The Acushnet Cedar Swamp is crossed by an active freight rail line under existing conditions. The reconstruction of these active rail lines would not create a new canopy gap, and would therefore not change the existing forest interior or edge conditions. The only change to bird habitat would be increased train passage.

Vernal Pools

The vernal pool analysis in the DEIS/DEIR sought to quantify the effects of impacts from the South Coast Rail project on vernal pools, vernal pool habitat, and associated upland habitat surrounding vernal pools. The analysis used the GIS coordinates for each vernal pool data point, and used 100 foot and 750 foot circles around each point to determine the extent of adjacent upland habitat and surrounding upland habitat.

The Secretary's Certificate required that the FEIR include an analysis of all vernal pools within 750 feet of either side of the right-of-way for the Stoughton Alternative. The existing MassGIS data layer was combined with all field survey and observation data in order to make a new data layer showing all NHESP certified, potential, and field surveyed vernal pools within 750 feet of either side of the right-of-way.

The original analysis did not attempt to quantify direct impacts to vernal pools themselves; rather, it defined direct impact as "loss of a wetland where a vernal pool occurs." The updated analysis clarifies impacts to vernal pools themselves, as well as habitat surrounding vernal pools. The different areas were defined as follows:

- Impacts to Vernal Pools: Direct impacts (fill) to vernal pools themselves
- Impacts to Vernal Pool Habitat: Impacts to any wetland area within 100 feet of the boundary of a vernal pool, where the pool is within that wetland
- Impacts to Upland Buffer Habitat: Impacts to any undisturbed, natural upland area within 100 feet of the boundary of a vernal pool
- Impacts to Surrounding Upland Habitat: Impacts to any undisturbed, natural upland area between 100 and 750 feet from the boundary of a vernal pool

The limits of each pool were estimated for all vernal pools within the right-of-way and for any pools that had any portion within 100 feet of the Limit of Disturbance (LOD). Since field delineation of every pool within 100 feet of the LOD in the field was not practicable, limits were established by examining aerial photographs and creating polygons in a GIS data layer to represent the boundary of each pool. 100 foot and 750 foot extents were then generated around these polygons, resulting in a larger area of analysis and a more accurate representation of the extent of actual pools, vernal pool habitat, upland buffer habitat, and surrounding upland habitat than simply assuming the pools to be points. Pools farther away from the LOD (i.e., pools that did not have any portion within 100 feet of the LOD) would not receive any direct impacts to either vernal pool habitat or upland buffer habitat from the South Coast Rail project. The GIS point locations were used to generate the 100 foot and 750 foot areas around these pools. Vernal pool habitat was delineated using the MassGIS wetland layer, along with the updated wetland delineations.

Once the 100 foot and 750 foot areas had been generated around each polygon and point, the impacts to each habitat category described above were calculated. Equal treatment has been given to all vernal pools and potential vernal pools within the Project study area, regardless of their certification status. This conservative approach likely includes some areas in the analysis that do not actually function as vernal pools in the landscape. PVPs that were visually inspected and determined not to function as vernal pools during investigations for the DEIR/DEIS were removed from the updated analysis. Impact calculations conservatively include areas on both sides of the right-of-way, even when separated by a section of berm or track, under the assumption that tracks and ballast are somewhat permeable to small animal movement. The majority of impacts, particularly to vernal pool habitat, occur in areas where the tracks are disused or have been

removed altogether, so use of habitat on both sides of the right-of-way is likely in most of the areas that will receive impacts.

Impacts calculated for upland buffer habitat and surrounding upland habitat did not include any areas of existing railbed or the surrounding ballast. The extent of ballast was not delineated in the field, but an approximation was made for the analysis by using a measurement of 10 feet to either side of the track centerline. Impacts to areas of upland buffer habitat and surrounding upland habitat also did not include any existing developed areas, including buildings and parking areas. Developed areas were estimated by using a land use data layer in the GIS analysis and subtracting any areas of development from impacted areas.

The impacts to vernal pools, vernal pool habitat, upland buffer habitat, and surrounding upland habitat are discussed in detail in this section. Impacts to vernal pools, as well as impacts all associated habitats for the Stoughton Alternative are shown in Figures 4.14-7, 4.14-8 and 4.14-9.

Impacts to Vernal Pools—The most ecologically important impacts are to vernal pools that would be directly filled, resulting in a permanent alteration of the pool. The total fill to vernal pools would be 0.53 acre, or 23,158 square feet, and would affect 19 vernal pools. Table 4.14-12 describes the impacts to vernal pools along the Stoughton Alternative project corridor.

Average depths were not calculated for each of the above pools, so the total volume of fill to vernal pools is not known. The amount of filled surface area in square feet gives an approximate measure of the relative size of disturbance to any given pool. Two vernal pools lie completely (or nearly so) in abandoned sections of the rail bed: PVP 20230 in Raynham and VP 13 in Taunton (Figure 4.14-7e). PVP 20230 would be filled completely, while VP 13 would be filled 96.4 percent, essentially a complete loss. One other pool, PVP 8286 in Freetown, would have a majority (59.8 percent) of its area filled (Figure 4.14-9b). The impacts to the other pools that would be directly affected range from 1.1 percent to 21.3 percent. Easton has the largest number of pools that would be directly affected (6 pools), while Freetown has the largest amount of fill proposed (10,065 SF). While it is impossible to avoid impacting vernal pools to some degree along the Stoughton Alternative, no direct filling would occur to any vernal pools in Canton, Berkley, Lakeville, New Bedford, or Fall River.

Figure 4.14-17 shows the distribution of the percentage impacts to vernal pools. Of the 19 vernal pools that are impacted, 11 pools would lose up to 10 percent or less of their total area, and 15 pools would lose 20 percent or less of their total area.

Table 4.14-12 Impacts to Vernal Pools of the Stoughton Electric Alternative

Municipality	Pools Affected	Amount of Fill (SF)	Approx. Size of Pool (SF)	Approx. Size of Pool (Ac.)	Percent of Pool Filled

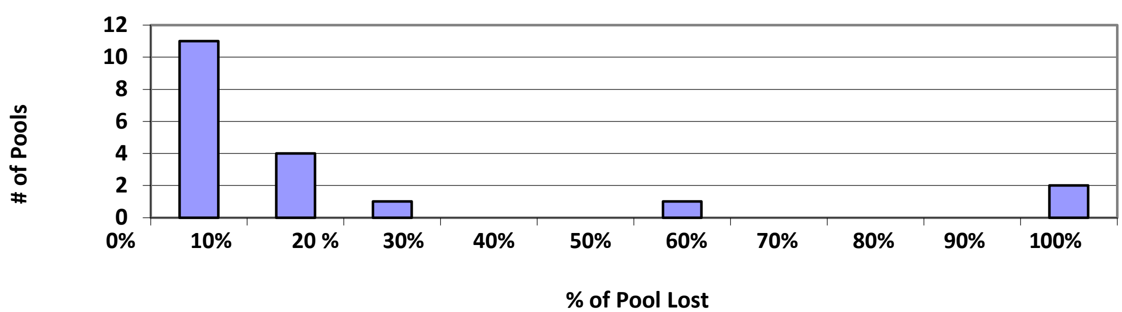
Figure 4.14-17 Percent Impacts to Vernal Pools Stoughton Electric Alternative



These results are based on preliminary design. In the final design phase of the project, additional small impacts may be avoided or minimized through different grading (for example, steepened slopes along the rail line). Additional design efforts would attempt to minimize impacts. These efforts are discussed in more detail in Section 4.14.3.6.

Impacts to Vernal Pool Habitat—Impacts to vernal pool habitat are defined as impacts to any wetland containing a vernal pool within 100 feet of the boundary of a vernal pool. The loss of vernal pool habitat would affect 40 vernal pools.

Table 4.14-13 describes the impacts to vernal pool habitat along the South Coast Rail project corridor. Where pools are in close proximity to one another, the impacted areas of vernal pool habitat overlap. In these cases, the impacts to the affected area of vernal pool habitat are identified as a whole, and the pools that make up each affected area are denoted. As a conservative measure, the entire area of the Hockomock Swamp under the proposed trestle in Easton was included in the calculation of total vernal pool habitat, since this entire area is known to provide good habitat for vernal pool amphibians. No impacts to vernal pool habitat would occur in the area under the trestle.

Totals	40	62,481			

A total of 30 areas would be impacted, affecting a total of 40 vernal pools. The largest impact to vernal pool habitat around any single pool would be to that of PVP 25087 in Taunton (Figure 4.14-7e), which would lose 100 percent of its vernal pool habitat. This vernal pool is a small pool surrounded mainly by upland areas, with all nearby wetlands lying entirely in the right-of-way. Although there are no other wetland areas contiguous to PVP 25087, a large wetland area of wetlands lies less than 200 feet to the east, giving this pool additional wetland habitat nearby. VP 13 would lose 26.4 percent of its vernal pool habitat; however, since this is one of the two pools that would be filled in completely, the loss of additional vernal pool habitat is moot. The impacts to the other pools and habitats that would be directly affected range from 0.3 percent to 24.9 percent. Easton has the largest number of pools that would be affected (13 pools), while Taunton has the largest amount of fill proposed (22,473 SF). While it is impossible to avoid impacting vernal pool habitat to some degree along the Stoughton Alternative, no impacts to vernal pool habitat would occur in Canton, Lakeville, or Fall River. Additionally, Stoughton and New Bedford would experience impact to vernal pool habitat associated with either one or two pools, totaling less than 500 SF in Stoughton and less than 1,300 SF in New Bedford.

Figure 4.14-18 shows the distribution of the percentage impacts to vernal pool habitat. Of the 30 areas impacted, 24 would lose 10 percent or less of their total vernal pool habitat, and 27 would lose 20 percent or less of their total vernal pool habitat.

Impacts to Upland Buffer Habitat—Impacts to upland buffer habitat are defined as impacts to any naturally-vegetated upland area within 100 feet of the boundary of a vernal pool. The loss of upland buffer habitat would affect 60 vernal pools. Table 4.14-14 describes the impacts to upland buffer habitat along the South Coast Rail project corridor. Where pools are in close proximity to one another, the impacted areas of upland buffer habitat overlap. In these cases, the analysis identifies the impacts to the affected area of upland buffer habitat as a whole, and denotes which pools make up each affected area. Impacts are calculated for the loss of undeveloped land with natural vegetation that could provide non-breeding and/or migratory habitat for vernal pool amphibians. Therefore impacts calculated to upland buffer habitat did not include any areas of existing rail bed or the surrounding ballast, which were estimated by using a measurement of 10 feet to either side of the track centerline. Impacts to and total areas of upland buffer habitat also did not include any existing developed areas, including buildings and parking areas. Developed areas were estimated by using a land use data layer in the GIS analysis and subtracting any areas of development from impacted areas. No impacts to upland buffer habitat would occur in the area under the proposed trestle in Easton.

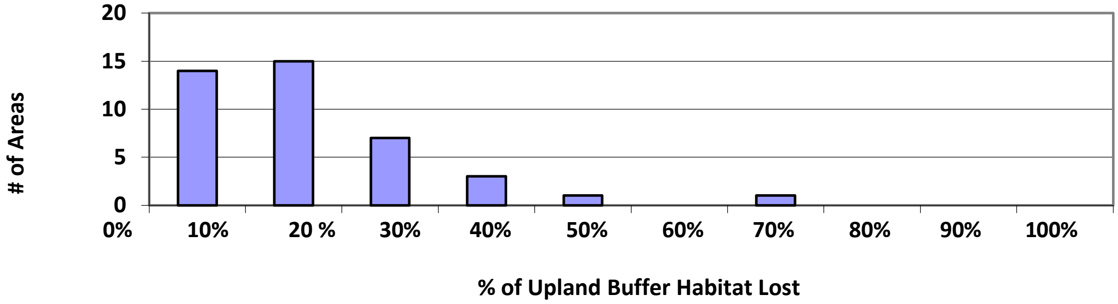
Totals	57	403,478	9.26			

A total of 41 areas would be impacted, affecting a total of 57 vernal pools. Impacts to upland buffer habitat would be generally larger than impacts to vernal pool habitat, both in terms of area in square feet and in terms of percentage of available upland buffer habitat associated with each vernal pool or cluster of pools. The majority of impact associated with constructing new tracks and widening existing tracks and berms involves existing uplands. The percentage impacts to upland buffer habitat are therefore greatest in areas where this type of habitat is limited to berms and slopes along large wetlands or wetland complexes. For example, the largest percentage impact to upland buffer habitat is at NHESP 3 in Raynham (Figure 4.14-7d), which would lose 66.9 percent of its upland buffer habitat. The nearby pool of PVP 20158 is approximately the same distance from the limit of disturbance as NHESP 3, but would lose only 33.0 percent of its upland buffer habitat. This lower percentage is due to the fact that PVP 20158 has additional upland area within 100 feet of the boundary of the pool, whereas the upland area within 100 feet of the boundary of NHESP 3 is mainly limited to the railroad berm.

Figure 4.14-19 shows the distribution of the percentage impacts to upland buffer habitat. Of the 41 areas impacted, 14 would lose 10 percent or less of their total upland buffer habitat, and 29 would lose 20 percent or less of their total upland buffer habitat. Twelve areas would lose more than 20 percent of their total upland buffer habitat. While impacts to upland buffer habitat can affect the ability of vernal pools to sustain viable populations, all affected pools have additional upland buffer habitat or surrounding upland habitat contiguous to their impacted upland buffer habitat, with the exception of pool NHESP 3.

Figure 4.14-19 Percent Impacts to Upland Buffer Habitat Stoughton Electric Alternative



Impacts to Surrounding Upland Habitat

Impacts to surrounding upland habitat are defined as impacts to any naturally vegetated upland area between 100 and 750 feet of the boundary of a vernal pool. For these pools, point locations were used to represent each pool. The loss of surrounding upland habitat would affect 147 vernal pools. Table 4.14-15 lists the impacts to surrounding upland habitat along the South Coast Rail project corridor. Where pools are in close proximity to one another, the impacted areas of buffer habitat overlap. In these cases, the impacts to the affected area of surrounding upland habitat are identified as a whole, and the pools that make up each affected area are denoted. Impacts are calculated for the loss of undeveloped land with natural vegetation that could provide non-breeding and/or migratory habitat for vernal pool amphibians. The impacts calculated for surrounding upland habitat did not include any areas of existing rail bed or the surrounding ballast, which were estimated by using a measurement of 10 feet to either side of the track centerline. Impacts to and total areas of surrounding upland habitat also did not include any existing developed areas, including buildings and parking areas. Developed areas were estimated by using a land use data layer in the GIS analysis and subtracting any areas of development from impacted areas. No impacts to surrounding upland habitat would occur in the area under the proposed trestle in Easton. For a single pool surrounded by completely undeveloped area, the total potential surrounding upland habitat would be over 40 acres.

Table 4.14-15 Impacts to Surrounding Upland Habitat of the Stoughton Electric Alternative

	Pools Affected	Area of Impact to Surrounding Upland Habitat (Ac.)	Total Area of Surrounding Upland Habitat (Ac.)	Percent of Upland Habitat Impacted

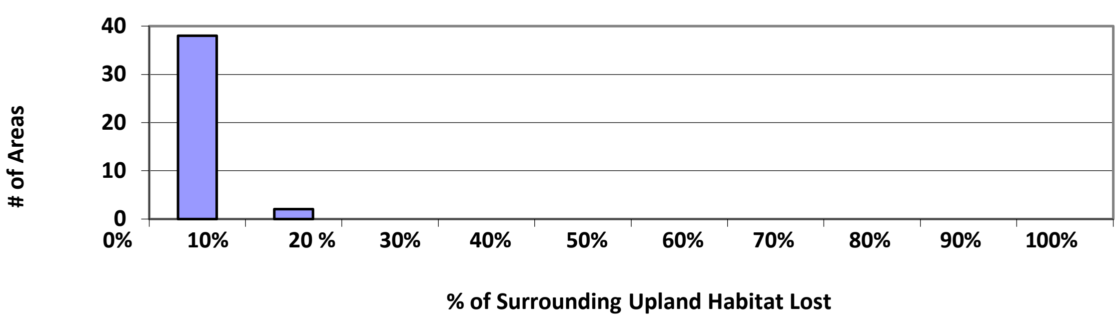
A total of 40 areas would be impacted, affecting a total of 136 vernal pools. While impacts to surrounding upland habitat are larger in terms of size than either vernal pool habitat or upland buffer habitat, the overall impacts would be negligible. The large total area of surrounding upland habitat around a given pool, or more often a cluster of pools, tends to ameliorate the impacts to surrounding upland habitat in any one area. The largest percentage impact to surrounding upland habitat is around the pair of pools PVP 20158 and NHESP 3 in Raynham (Figure 4.14-7d), which would lose 16.4 percent of their surrounding upland habitat. This impact is due to a combination of significant wetland areas surrounding these two pools as well as large developed areas on the eastern side of the right-of-way. The pair of pools PVP 23784 and CVP 2140 in Stoughton (Figure 4.14-7b) would lose 15.9 percent of their surrounding upland habitat from constructing the North Easton station. Impacts to pools already segregated from the right-of-way by an existing road, such as PVP 4291 in Canton (Figure 4.14-7a), are unlikely to have any real effect on the pool in question. Conversely, in areas such as that around the pair of pools PVP 23778 and PVP 23779 in Stoughton (Figure 4.14-7b), impacts are more likely to exclusively affect PVP 23778 due to the separation of PVP 23779 from the right-of-way, again by an existing roadway. Still, the overall effects to either pool would be very small since both have a large contiguous area of surrounding upland habitat around the pool. There are no pools or cluster of pools along the length of the Stoughton Alternative corridor that would have a large percentage of surrounding upland habitat impacted.

Figure 4.14-20 shows the distribution of the percentage impacts to surrounding upland habitat. Of the 40 areas impacted, 38 would lose 10 percent or less of their total surrounding upland habitat, and all 40 would lose less than 20 percent of their total surrounding upland habitat.

Figure 4.14-20 Percent Impacts to Surrounding Upland Habitat Stoughton Electric Alternative



Fragmentation Effects

Habitat fragmentation can occur to individual pools as well areas with multiple pools, and can affect the species that use vernal pools by restricting or cutting off their access to vernal pool habitat, upland buffer habitat, and surrounding upland habitat.

Fragmentation of individual pools would occur when a given pool has a large area of an associated habitat on the opposite side of the tracks, and little to no associated habitat on the same side of the tracks. Most often the habitat on the same side of the tracks is either cut off by existing roadways or is developed with structures or parking areas. For these pools, the vernal pool amphibians that use the pool will spend the majority of the year in the more naturally vegetated areas on the opposite side of the tracks, crossing over to use the pool during breeding season. Constructing new tracks, widening berms, and constructing steeper slopes and retaining walls can all separate vernal pool amphibians from their necessary breeding habitat, thereby reducing the effectiveness of the pool. Along the Stoughton Alternative corridor, the only vernal pool that would experience these effects to is NHESP 3 in Raynham (Figure 4.14-7d). This pool at the southern end of the Hockomock Swamp past the end of the trestle, and is part of the large Hockomock wetland complex. Constructing the railroad would impact the majority of the upland buffer habitat of this pool, and the majority of the surrounding area is wetland. The small amount of undeveloped upland buffer habitat across the existing berm would be cut off from NHESP 3. No other pools have any of their associated habitats cut off from the South Coast Rail project. The majority of pools occur in less developed areas, and have contiguous additional vernal pool habitat, upland buffer habitat, and surrounding upland habitat available to vernal pool amphibians that use the pools. Even pools in more densely developed areas are either already separated from the right-of-way by an existing road (such as PVP 4291 in Canton, Figure 4.14-7a), or would not experience separation of the pool from additional areas of associated habitats by constructing the railroad.

Larger-scale fragmentation effects can occur in areas with multiple pools. These areas may have pools separated from one another due to fragmentation from the new railway. New tracks, track widening, steepened slopes, and retaining walls can all create significant barriers to animal movement between pools, where before the barrier effects of the abandoned railroad bed may have been only moderate or minimal. This can affect the health of the entire pair, cluster, or system of pools by preventing animal movement between them. Table 4.14-16 highlights areas where pools are likely to be separated from one another or have their current level of separation increased. Pairs or clusters of pools where fragmentation occurs within 100 feet represent more tightly associated pools. Pools already separated by existing roadways or other developed areas that provide barriers to movement were not considered.

New fragmentation effects would occur entirely in Easton, Raynham, and Taunton. One additional cluster in Freetown already has PVP 8283 separated from PVPs 8284, 8285, 8286, and 8287 (Figure 4.14-9b) by an existing maintained railway, so additional fragmentation effects are unlikely. Separating pools from one another can decrease the amount of associated vernal pool habitat, upland buffer habitat, and supporting upland habitat available to all pools in the cluster or pair. This can affect species density and the ability of the pool to provide adequate breeding habitat, if the majority of the organisms that use the pool originate from the other side of the railroad. Fragmentation is likely to have the largest effects in cases where one pool is newly separated from a cluster, or where a pair of pools is separated to create two single pools, and when the pools are close together (i.e., within 100 feet of one another). This would occur, for example, in Easton, where VP-3 is separated from a cluster of four other pools (Figure 4.14-7b). In the areas of fragmentation listed in Table 4.14-16, there are no cases where one pool is separated from a pair or cluster without at least some extant surrounding habitat of its own.

Summary of Impacts

Table 4.14-17 provides a summary of the impacts to vernal pools and surrounding habitat of the Stoughton Electric Alternative. The majority of impacts to vernal pools occur on the Stoughton Line. The Stoughton line contains 16 of the 19 pools that would experience direct impact (fill) from the Project, 28 of the 40 pools that

would experience impacts to vernal pool habitat, 42 of the 57 pools that would experience impacts to upland buffer habitat, and 88 of the 136 pools that would experience impacts to surrounding upland habitat.

Table 4.14-17 Summary of Vernal Pool Impacts of the Stoughton Electric Alternative

Pools with Direct Fill / Amount of Fill	Pools with Impacts to Vernal Pool Habitat	Pools with Impacts to Buffer Habitat	Pools with Impacts to Surrounding Upland Habitat
19 / 0.53 Ac.	40 / 1.43 Ac.	57 / 9.29 Ac.	136 / 43.40 Ac

The following points summarize the impacts by municipality.

- Canton: There are no impacts in Canton. The one vernal pool within 750 feet of the right-of-way is already separated from the right-of-way by an existing roadway.

- Stoughton: Impacts in Stoughton are small. One pool (PVP 23791) would receive direct fill but has large contiguous areas of adjacent vernal pool habitat, upland buffer habitat, and surrounding upland habitat around it. No clusters of pools are present.

- Easton: Six pools would receive direct fill in Easton, although only one (PVP 7222) would lose greater than 20 percent of its area. While upland buffer habitat within 100 feet would be impacted around several pools, in all cases these pools have additional surrounding upland habitat between 100 and 750 feet away. Several clusters and pairs of pools are in close proximity to the right-of-way and would experience fragmentation both of associated habitats and of entire pools from one another. The majority of these clusters and pairs are in close association with one another (i.e., pools are within 100 feet of each other or within 100 feet of another pool in the same cluster).

- Raynham: One pool (PVP 20230) would be completely filled for the project, resulting in a loss of the pool as well as the utility of its associated habitats. Five other pools would also receive direct fill. One pool (NHESP 3) would lose upland buffer habitat and does not have contiguous adjacent upland habitat nearby. Two clusters of pools would experience fragmentation within 750 feet, plus an additional pair of pools which would experience fragmentation within 100 feet.

- Taunton: One pool (VP 13) would be filled 96.4 percent, essentially a complete loss. Four additional pools would receive direct impact. In addition, Taunton has some of the largest impacts to both vernal pool habitat and upland buffer habitat. However, in all cases these pools have additional habitat between 100 and 750 feet away. Taunton also has several clusters of pools that would experience fragmentation within 750 feet, and one cluster within 100 feet.

- Berkley: Impacts in Berkley would be small. No pools would receive direct fill, and impacts to vernal pool habitat are small. Impacts to upland buffer habitat, particularly around PVP 2318 and PVP 2319 are more significant, but these pools have additional surrounding upland habitat. No cases of fragmentation between pools occur in Berkley.

- Lakeville: Impacts in Lakeville are very small. Few vernal pools exist along the right-of-way and no pools would receive direct fill. Impacts to other associated habitats are also small, and there are no cases of fragmentation between pools.

- Freetown: One pool (PVP 8286) in Freetown would receive fill to a majority of its area, and would also receive an impact greater than 25 percent to both vernal pool habitat and upland buffer habitat. The nearby pool of PVP 8284 would also receive direct fill as well as impacts to vernal pool habitat and upland buffer habitat. In both cases these pools have additional habitat between 100 and 750 feet away. The remainder of the pools in Freetown do not receive large impacts.

- New Bedford: Impacts in New Bedford would be very small. Few pools exist along the right-of-way. No pools would receive direct impacts, and impacts to other associated habitats are small, with exception of one large impact to the upland buffer habitat of CVP 2647. However this pool has large unfragmented areas of additional surrounding upland habitat.

- Fall River: There are no impacts in Fall River.

Overall, impacts to vernal pools along the South Coast Rail project corridor are small and are not likely to compromise the functions of pools or communities of pools along the route. Two vernal pools would be filled completely (PVP 20230 in Raynham and VP 13 in Taunton, Figure 4.14-7e), and one additional pool would lose a majority of its area (PVP 8286 in Freetown, Figure 4.14-9b). Of the remaining pools, no pool or group of pools would lose a large portion of its vernal pool habitat, upland buffer habitat or supporting upland habitat. Additionally, pools that lose areas of associated habitats have additional, larger contiguous areas of these habitats adjacent to them, with the exception of NHESP 3 in Raynham (Figure 4.14-7d).

Appendix 4.14-C shows the impacts to vernal pools that would be directly filled, along with the impacts to all associated habitats: vernal pool habitat, buffer habitat, and surrounding upland habitat. Where pools are in close proximity to one another, the impacted areas of habitat will overlap; a given habitat area can therefore have impacts from multiple pools. The table shows the impacts to each habitat area as a whole. Where multiple pools contribute to an affected area, the number of pools associated with each given habitat area are given.

Fish and Wildlife Passage

This part discusses fish and wildlife crossings. Culverts and bridges along the South Coast Rail Stoughton Alternative alignment are described and a plan for providing crossings in areas with high biodiversity value to enhance fish and wildlife passage is provided.

A detailed inventory of bridges and culverts was conducted to identify the location, condition, and function of each structure. Dimensions, construction materials, and railroad bed characteristics (such as condition and depth of cover) were recorded. For this biodiversity assessment, the subset of bridges and culverts with potential ecological value was determined by reviewing wetland mapping (as depicted in the Abbreviated Notice of Resource Area Determination [ANRAD] for each municipality), surrounding land use (as visible in aerial photographs), and other ecological setting features (as modeled by CAPS[67])

[67] UMass Extension. 2011. CAPS Index of Ecological Integrity. http://umasscaps.org/. The CAPS model output indicates areas with a high (over 50 percent) Index of Ecological Integrity (IEI). CAPS maps for each town along the Stoughton Alternative are provided in Appendix C.

of the complete bridge and culvert inventory. The inventory of this subset of bridges and culverts is provided in Appendix 4.14-A and summarized in this section.

There are 128 structures (23 bridges and 105 culverts) along the Stoughton Alternative alignment (comprised of the Stoughton Line, New Bedford Main Line, and Fall River Secondary) that may have biodiversity value by connecting ecosystems, which can allow fish and wildlife to pass from one side of the tracks to the other. Many of these structures also have a hydrologic function, allowing water to flow under or through the railroad structure (subgrade, ballast, ties, and tracks). Bridges that convey roads under or over the railroad bed will also be improved for the project but do not have an ecological function connecting ecosystems and are therefore not included in this biodiversity evaluation. Bridges and culverts that have been replaced prior to the South Coast Rail project are also not included in this biodiversity evaluation, as are 29 culverts within the right-of-way that do not cross under the railroad bed (but instead are parallel to it) and therefore do not connect ecosystems bisected by the railroad.

Proposed Bridge and Culvert Replacement

Most of the bridges and culverts along the Stoughton Alternative alignment will be replaced to meet engineering requirements for operation of the South Coast Rail. The track design is conceptual at this stage but takes into consideration operational and safety requirements as well as the gentle elevation change requirements of a fixed guideway transit system. Railroad track elevation changes and curves must be gradual to accommodate the design requirements for a safe high speed train track. Additionally, the railroad bed must meet certain width and depth specifications (depending on the nature of the underlying ground surface) to provide proper track support and ballast drainage. The following sections describe the engineering evaluation of bridges and culverts conducted to support the preliminary design.

Bridges—The 23 existing bridges considered in this biodiversity evaluation are in deteriorating condition and have insufficient capacity for the expected loads and speeds of the South Coast Rail trains. Many of the bridges along the Stoughton Alternative will be replaced to meet current engineering standards for the high-speed commuter rail service, regardless of whether or not the bridges span roads or waterbodies. One new bridge to replace a washed-out culvert, and a new trestle through Hockomock Swamp, will be constructed. Table 4.14-18 describes the proposed substructure for the bridges and trestle that could impact fish and wildlife passage; typical bridge cross-sections for single-span and two-span structures are depicted in Figures 4.14-21a and b, respectively.

Piers or pilings supporting existing multiple-span bridges (see Table 4.14-18) will be replaced by a single pier at the center of a two-span structure, minimizing impacts to stream hydrology and fish habitat. Abutments for most of the bridges will be replaced, offering an opportunity to improve wildlife passage on stream and river banks. Typically, existing piles would be removed and one new cast-in-place concrete pier would be constructed in the center of the span. New cast-in-place concrete abutments would be constructed behind the existing timber crib abutments, which would then be partially removed to an elevation equal to the river’s average seasonal high water elevation.

Table 4.14-18 Proposed Bridge Substructure Construction

Bridge	Figure Number	Proposed Substructure Construction
Stoughton Line		
Forge Pond	4.14-11a	No change to existing abutment location. The new superstructure (above or adjacent to existing historic arch structure) would be supported on adjacent augured piles or drilled shafts.
Mill Brook (Beaver Meadow Brook)	4.14-11a	No change to existing abutment location. The new superstructure (above or adjacent to existing historic arch structure) would be supported on adjacent augured piles or drilled shafts.
Cowessett Brook (Whitman Brook)	4.14-11b	New abutments would be constructed behind existing abutments, which would then be removed.
Quessett Brook (Small Creek)	4.14-11b	Existing stacked stone abutments would be rehabilitated to accommodate increased loads; there would be no change in abutment location.
Black Brook	4.14-11c	New bridge would be constructed to replace washed out culvert. Cast-in-place concrete abutments would be constructed beyond the banks of Black Brook so as to not change the hydrology of the stream or conditions of the surrounding wetlands, and to provide shelves for wildlife passage.
Hockomock Swamp	4.14-11c	New 8,500-foot long trestle over existing rail bed, constructed on steel h-piles or concrete piles at 30-foot intervals.
Pine Swamp Brook #1	4.14-11d	The design for this structure has not yet been determined, but would provide wildlife shelves.
Pine Swamp Brook #2	4.14-11d	The design for this structure has not yet been determined, but would provide wildlife shelves.
Taunton River (@MP 34.38)	4.14-11e	Existing piles would be removed and one new cast-in-place concrete pier would be constructed in the center of the span. New abutments would be constructed behind the existing abutments, which would then be removed.
Taunton River (@MP 34.62)	4.14-11e	Existing piles would be removed and one new cast-in-place concrete pier would be constructed in the center of the span. New abutments would be constructed behind the existing abutments, which would then be removed.
Taunton River (@MP 34.73)	4.14-11e	Existing piles would be removed and one new cast-in-place concrete pier would be constructed in the center of the span. New abutments would be constructed behind the existing abutments, which would then be removed.
Mill River	4.14-11e	New abutments would be constructed behind the existing abutments, which would then be removed.
New Bedford Main Line		
Taunton River (@MP 35.56)	4.14-11e	Existing piles would be removed and one new cast-in-place concrete pier would be constructed in the center of the span. New abutments would be constructed behind the existing abutments, which would then be removed.
Brickyard Road	4.14-11e	Existing stacked stone abutments would be rehabilitated to accommodate increased loads; there would be no change in abutment location.
Cotley River (@MP 38.93)	4.14-12a	New abutments would be constructed behind the existing abutments, which would then be removed.

Bridge	Figure Number	Proposed Substructure Construction
Cotley River (@MP 39.46)	4.14-12a	New abutments would be constructed behind the existing abutments, which would then be removed.
Cedar Swamp River	4.14-12b	New abutments would be constructed behind the existing abutments, which would then be removed.
Fall Brook	4.14-12b	New abutments would be constructed behind the existing abutments, which would then be removed.
Fall River Secondary		
Cedar Swamp River	4.14-13a	Existing piles would be removed and one new concrete pier would be constructed in the center of the span. New abutments would be constructed behind the existing abutments, which would then be removed.
Farm Road	4.14-13b	Existing stacked stone abutments would be rehabilitated to accommodate increased loads; the abutment location would not be changed.
Farm Road	4.14-13b	This bridge will be filled in, as the existing dirt road spanned by the bridge has been abandoned.
Miller's Cove	4.14-13b	New abutments would be constructed to replace the existing stacked stone abutments; the abutment location would not be changed.
Collins Road	4.14-13b	Existing stacked stone abutments would be rehabilitated to accommodate increased loads; the abutment location would not be changed.
Ashley's Underpass	4.14-13b	Existing stacked stone abutments would be rehabilitated to accommodate increased loads; the abutment location would not be changed.
Channel near Battleship Cove	4.14-13c	The design for this structure has not yet been determined.

Culverts—The 105 existing culverts considered in this biodiversity assessment along the three railroad lines range in condition from good to poor, with most performing their hydrologic function but many partially or fully collapsed, buried, or plugged. Depending upon the recommendations made to enhance ecological connections, project requirements, and engineering constraints, these culverts may be replaced, left in place, or abandoned.

From an engineering perspective alone, culvert replacement would be based on a variety of existing conditions or project needs. Culverts that are no longer performing their hydrologic function (e.g., are plugged or collapsed) or that exhibit structural failure would likely be replaced. Culverts that would need to be extended to accommodate a change in the track for the South Coast Rail project, such as relocating the track or installing double tracks where a single track currently exists, would also be replaced. Culverts that are in good condition, are functioning properly, and meet the requirements of the South Coast Rail project, do not require any action.

Other Important Habitat Areas

The Stoughton Alternative also passes the Stoughton Memorial Conservation Lands (including the Bird Sanctuary) north of the proposed North Easton station. The railroad tracks and ties are currently in place through this section, although the canopy has closed over the out-of-service tracks. Restoring the tracks would require removing vegetation along the right-of-way, which would result in a new "edge effect"

that would alter the microhabitat characteristics of wooded areas adjacent to the rail, potentially reducing the ability of this area to support forest interior species.

Indirect Impacts of the Stoughton Electric Alternative

The analysis of indirect impacts evaluates the effects of the Stoughton Electric Alternative on key elements of biodiversity. Where the Stoughton Alternative's impacts on natural communities would occur entirely along the edge of existing active rail lines, indirect impacts to natural communities, wildlife or fisheries are anticipated to be minor and restricted to the edges of these communities. The Stoughton Alternative also has the potential to cause larger indirect effects to natural communities where it would reconstruct an out-of-service rail line, particularly along the Stoughton Line from Foundry Street in Easton to Thrasher Street in Taunton.

Vegetation Management—Right-of-way maintenance is critical to the protection of the tracks and ties and to maintaining railroad safety. Right-of-way maintenance can only be done in accordance with an approved Vegetated Management Plan (VMP) and Yearly Operating Plan (YOP) that have been reviewed by the Massachusetts Department of Food and Agriculture (DFA) and made available for public comment. These management plans are developed in accordance with the DFA's regulations, which prohibit or restrict the application of herbicide in sensitive areas such as close proximity to wetlands and public or private drinking water supplies. Under existing conditions and the No-Action Alternative, CSX Corporation maintains the track from Whittenton Junction to Cotley Junction in Taunton, MassCoastal Railroad maintains the track from Cotley Junction to New Bedford and Fall River, and MBCR maintains the track north of Stoughton Station in accordance with approved VMPs and YOPs.

To protect state-listed species, as well as aquatic organisms and water quality, the applicant has committed to treat the entire portion of the corridor through the Hockomock Swamp (from Foundry Street to the Raynham Park Station) and through Pine Swamp as No-Application sensitive areas. In addition, in accordance with the DFA requirements, the following will be designated as No-Application zones:

- Areas within 10 feet of a surface water or wetland
- Areas within 50 feet of a private drinking water supply
- Areas within 100 feet of a surface water public water supply
- Areas within 400 feet of a public water supply well (Zone 1)

These specific locations will be identified and shown on detailed project plans during the subsequent final design and permitting phase of the project, when a VMP is developed. The 1" = 1250' scale graphics used to depict the Stoughton Alternative for the purposes of the DEIS/DEIR are not sufficiently detailed to allow these areas to be shown.

The vast majority of areas disturbed for construction (extending 14 feet to each side of the track centerline, for a total width of 28 feet for single track and 42 feet for double track) will be surfaced with ballast and will be within the area where vegetation must be managed for railroad safety. These areas will not be allowed to revegetate. Disturbed areas outside of the trackbed would be seeded with an appropriate stabilization seed mix using native species. These seeded areas would be expected to revegetate within one growing season.

Habitat Fragmentation—Comments on the DEIS/DEIR, request that the applicant update the discussion of reference studies regarding habitat fragmentation impacts of linear transportation infrastructure with more recent studies, as available. These comments also suggested that the applicant should consider wildlife habitat evaluations for the portions of the track that will fragment locally important wildlife habitats, and specifically assess the impacts to wildlife movement in the segment of track adjacent to the Acushnet Cedar Swamp.

Important Wildlife Habitats—In November, 2011 the UMass Extension Center for Agriculture, in conjunction with DEP, produced Important Wildlife Habitat maps. These maps are based on the CAPS integrated index of ecological integrity and show the areas in each municipality that fall into the top 40 percent for IEI value.[68] According to the DEP Wildlife Habitat Protection Guidance, these Important Wildlife Habitat polygons are considered Designated Habitat of Potential Regional or Statewide Importance. Wetland impacts, above the regulatory thresholds established in 310 CMR 10.00 for each resource area, may trigger the requirement for detailed wildlife habitat evaluations as described in Appendix B of the DEP Guidance.[69]

The Stoughton Alternative does not cross any Important Wildlife Habitat in Canton, Stoughton, Taunton, New Bedford or Fall River. The alignment crosses Important Wildlife Habitat in the following locations:

- Easton: the Hockomock Swamp south of Foundry Street
- Raynham: the Hockomock Swamp north of the former Raynham Greyhound Park, a small area north of Bridge Street, and the Pine Swamp west of the railroad
- Berkley: the area between Cotley Street and Padelford Street
- Lakeville: along the New Bedford Main Line between Malbone Street and Howland Road (the Assonet Cedar Swamp), and an area south of Howland Road
- Freetown: along the New Bedford Main Line north of Chace Road and a small area between Chace Road and Braley Road

Detailed wildlife habitat evaluations will be required in these areas as part of the subsequent Notice of Intent filings for the Stoughton Alternative, once final design plans have been developed and wetland impacts have been more precisely determined. Such detailed evaluations are not appropriate or feasible at this planning level.

Predation is an indirect effect associated with forest fragmentation, and may increase if opportunist predators such as crows and raccoons move into the edges adjacent to the project alignment. However, the existing railbed is open and used as a trail, so there are likely to be predation-related edge effects under existing conditions. The existing upland berm will not be widened through the Hockomock Swamp, and therefore the possibility that this will be used as a trail by ground predators is not likely to be substantially greater than under existing conditions.

[68] http://www.umass.edu/landeco/research/caps/dep/dep.html, accessed 15 March 2012.
[69] Department of Environmental Protection, Wildlife Habitat Protection Guidance, 2006.

There may also be increased brood-parasitism on songbirds if brown headed cowbirds colonize the edges adjacent to the rail. However, it is unlikely that large numbers of cowbirds will colonize the reconstructed right-of-way because the increase in canopy width is minimal.

Acushnet Cedar Swamp—The active freight railroad passes along the east edge of the Acushnet Cedar Swamp between the New Bedford Industrial Park (Samuel Barnett Boulevard) and Route 140. The land east of the railroad is occupied by the industrial park, a large industrial complex accessed from Welby Road, a residential neighborhood, and Route 140, a divided highway with two travel lanes in each direction. The DEP Important Wildlife Habitat map for New Bedford shows Important Wildlife Habitat only west of the railroad. A wetland (NB-20) is also located east of the railroad, south of the Industrial Park, west of Doreen Street, and north of Route 140. It is connected to Acushnet Cedar Swamp via culverts under the track and the linear channel adjacent to the Industrial Park, also east of (and parallel to) the railroad line. Therefore, this wetland not a part of the mapped DEP Important Wildlife Habitat, but there may be some movement of wetland-dependent wildlife between the Acushnet Cedar Swamp and NB-20, possibly warranting new between-the-tie crossings at this location.

Additional Information on Barrier Effects—A literature search to identify additional scientific studies on the barrier effects of railroads was undertaken, including review of Environmental Impact Statements currently or recently prepared by the FRA.[70] The search did not identify any additional information on the barrier effects of railroads, although one paper suggested that roads and railroads may restrict bumblebee movement, fragmenting both bumblebee populations and also restrict pollen transfer between plant populations.[71]

Noise Impacts to Wildlife—Comments on noise included requests that the project incorporate strategies to minimize noise impacts on wildlife during construction in ecologically sensitive areas, that the FEIS/FEIR provide additional information about noise impacts to wildlife in ecologically sensitive areas, and that additional mitigation measures be identified. In particular, these comments focused on the Acushnet Cedar Swamp in New Bedford, which has been designated as a National Natural Landmark by the National Park Service and which is owned by the Division of Conservation and Recreation as the Acushnet Cedar Swamp State Reservation.

Noise Impacts to Wildlife – National Natural Landmark (NNL) Acushnet Cedar Swamp—In the Acushnet Cedar Swamp section of the New Bedford Main Line, trains are anticipated to be traveling at approximately 100 miles per hour (1.6 miles per minute, 140 feet per second). At this speed, with an 8-car train, it will take a train less than 6 seconds to pass any given spot. The duration of the noise (88 dB) at any location would be 6 seconds, repeated for every train pass (20 times per day). Northbound trains will blow horns ¼ mile south of the Samuel Barnett Boulevard grade crossing, resulting in higher noise levels (105 dB) in this ¼ mile section for the 6-second period. Noise impacts to wildlife will therefore be extremely short in duration. There will not be prolonged exposure to noise that would disrupt breeding or feeding activity.

No measures are necessary or proposed to reduce train noise during wildlife breeding seasons. Such measures are not reasonable, as there are no adverse noise impacts anticipated, and it is not reasonable

[70] http://www.fra.dot.gov/rpd/freight/250.shtml, accessed March 15, 2012

[71] Bhattachyara, M., R.B. Primack and J. Gervein. 2003. Are roads and railroads barriers to bumblebee movement in a temperate suburban conservation area? Biological Conservation 109:37-45.

to reduce train service to New Bedford. Trains are required to sound horns as they approach roadway at-grade crossings, in compliance with FRA safety regulations.

All efforts will be taken to avoid construction during the avian breeding season (May through June) adjacent to the Acushnet Cedar Swamp State Reservation. In all cases construction will be limited to normal daylight hours, which will avoid interference with amphibian breeding calls.

Findings of the CAPS Model—The CAPS model used for the South Coast Rail project evaluated the ecological integrity of the landscape corridors adjacent to each of the alternatives considered in the DEIS/DEIR in the absence of the South Coast Rail, and evaluated the change in ecological integrity with each alternative, measured in IEI units. The model included both the physical barrier effects of the South Coast Rail alternatives (measured as the presence or absence of rail tracks and ballast, the number of tracks, the presence and height of a trestle, and the presence and height of retaining walls) and the noise or disturbance effects of the South Coast Rail alternatives (measured as the number of trains per day and the number of cars per train).

The CAPS analysis is a landscape-level tool useful in understanding secondary impacts to biodiversity and long-term biodiversity shifts that may result from a particular action, rather than the localized smaller impacts resulting from wetland fills.

The analysis showed that the No-Action Alternative had some level of reduced connectedness resulting from the presence of a railbed and culverts along the entire length of the Stoughton route. This railbed with culverts, even in the absence of tracks or rail traffic, represents a partial barrier to the movement of aquatic organisms. The changes in the IEI values as a result of the South Coast Rail project are due to decreased connectedness that result from constructing tracks on ballast, constructing a trestle, or constructing retaining walls (all of which serve, to varying degrees of severity, as barriers to animal movement) or decreased connectedness that results from adding or increasing train traffic. Noise and physical disturbances, to varying degrees of severity depending on the frequency of train movements and the length of the trains, cause wildlife to avoid areas near tracks or avoid crossing tracks.

The CAPS analysis showed that the Stoughton Alternative would result in the loss of IEI units, as shown in Table 4.14-19. Not unexpectedly, the majority of the loss of connectivity (64 percent) would occur north of Weir Junction, where there is no existing rail traffic. The Hockomock trestle would have less impact on connectedness than an at-grade track as it would present less of a barrier to wildlife movement.

Table 4.14-19 Loss of Ecological Integrity–Stoughton Alternative[1]

Option	Total Loss	Loss North of Weir Junction
With Trestle	474.5	302.0
Without Trestle	481.8	309.3

1 Measured in Index of Ecological Integrity Units

Stoughton Diesel Alternative

The Stoughton Diesel Alternative generally would have the same direct and indirect effects to biodiversity as the Stoughton Electric Alternative. However, since there would be no overhead catenary structures or wires, the Stoughton Diesel Alternative would have a reduced impact to the movement of birds across the track. Because this alternative would not require power substations, the Stoughton

Diesel Alternative would have a reduced direct impact to natural communities (1.95 acres) when compared to the Stoughton Electric Alternative.

Whittenton Electric Alternative

The Whittenton Electric Alternative includes reconstructing the Stoughton Line from Canton to Route 138 in Raynham, reconstructing the abandoned Whittenton Branch from Raynham Junction to Whittenton Junction in Taunton, and improving the existing active Attleboro Secondary from Whittenton Junction to Weir Junction. Various traction power substations and an overhead catenary system would be constructed in the same locations as for the Stoughton Alternative. A section of the out-of-service line crosses land within the Hockomock Swamp ACEC.

Biomap Core Habitats

The Whittenton Alternative would cross Biomap Core Habitat in two areas. The Hockomock Swamp, from Foundry Street in Easton south to Bridge Street in Raynham, is designated as Core Habitat. The Whittenton Electric Alternative would create a barrier to wildlife movement through portions of the Hockomock Swamp area (north of the proposed trestle and south of Raynham Park station). This barrier effect is likely to fragment populations of small vertebrates that are unable to cross the railroad tracks. The portion of the Whittenton Electric Alternative that is a proposed trestle (approximately 8,500 feet long) would not impede wildlife movement.

The Whittenton Electric Alternative would create a new canopy gap through portions of the Hockomock Swamp, primarily from Foundry Street south to the proposed Raynham Park station, where the forest canopy has closed over the railbed since the tracks were removed. This canopy gap could impede the movement of forest interior birds across the right-of-way, reducing the effective size of the forest block, and would create new “edge effects” of increased light and temperature, and decreased humidity, adjacent to the right-of-way. The barrier effects would extend upward from the tracks as a result of the overhead catenary system.

Living Waters

The Whittenton Alternative is adjacent to Living Water Core Habitat (LW080) near a reach of the Taunton River that provides habitat for Atlantic sturgeon. As noted in Section 4.15.3.3, the NMFS stated it is unlikely that any species listed under their jurisdiction will be exposed to any direct or indirect effects of the proposed South Coast Rail project. The right-of-way crosses this section of the Taunton River for approximately 125 feet, south of Weir Junction in Taunton (Figure 4.14-3a). The proposed reconstruction would not have a direct or indirect effect on the ability of the Taunton River to support aquatic biodiversity.

Portions of the Acushnet Cedar Swamp, particularly Turner Pond, are designated as Living Waters. The proposed reconstruction of the New Bedford Main Line would be approximately 7,500 feet west of Turner Pond and would not have a direct or indirect effect on the ability of the pond to support aquatic biodiversity.

Fisheries Habitat

The Stoughton Alternative crosses Whitman Brook, Queset Brook, Black Brook, Pine Swamp Brook, Taunton River, Mill River, Cotley River, Cedar Swamp River, and Fall Brook which are all important fisheries habitats. The proposed alternative would reconstruct existing bridges at Whitman Brook, Queset

Brook, Black Brook, Pine Swamp Brook, Cedar Swamp River and the Taunton River, and would construct a new bridge at Black Brook (the former rail bridge was washed out). These bridges would be reconstructed with the same or wider opening, maintaining habitat connectivity and the riverine substrate. The capacity of these waters to support aquatic diversity would not be adversely affected.

According to the Massachusetts Department of Fish and Wildlife comment letter on the DEIS/DEIR, fisheries surveys of the Mill River yielded 10 species, including American eel, black crappie, bluegill, brown bullhead, chain pickerel, common shiner, largemouth bass, pumpkinseed, redfin pickerel and tessellated darter. The NHESP restricts construction activities related to the Mill River to low flow periods of the year in order to prevent impacts to fisheries.

Breeding Bird Diversity

Potential breeding birds along the Whittenton Alternative are similar to Stoughton Alternative (including the Southern Triangle) as detailed above.

Vernal Pools

This section presents a vernal pool assessment, including indirect impacts, to wetland and upland habitat for vernal pool up to 750 feet on either side of the right-of-way of the Whittenton Branch. Similar to the Stoughton Alternative the analysis identified impacts to vernal pools as well as different areas surrounding vernal pools:

Whittenton Branch and Attleboro Secondary—The most ecologically important impacts are to vernal pools that would be directly filled, resulting in a permanent alteration of the pool. The total fill to vernal pools would be 0.36 acre, or 15,465 square feet, and would affect 10 vernal pools.

Table 4.14-20 describes the impacts to vernal pools along the Whittenton Alternative project corridor.

Table 4.14-20 Impacts to Vernal Pools–Whittenton Alternative

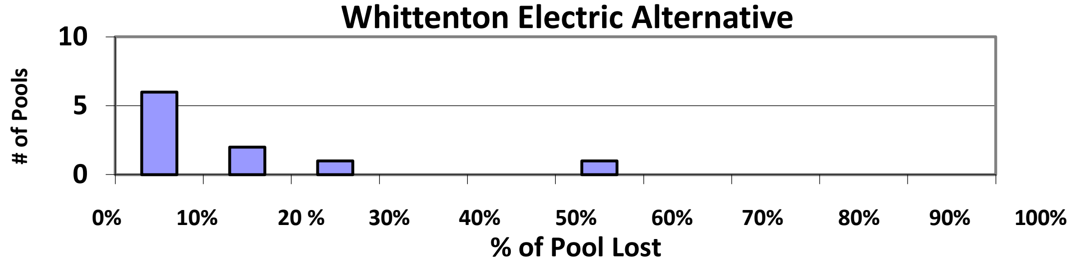
Municipality	Pools Affected	Amount of Fill (SF)	Approx. Size of Pool (SF)	Approx. Size of Pool (Ac.)	Percent of Pool Filled
Stoughton	PVP 23791	1,480	8,579	0.20	17.2%
Stoughton Total	1	1,480	8,579	0.20	
Easton	PVP 7222	2,197	10,324	0.24	21.3%
	VP-10	112	2,373	0.05	4.7%
	EA-2	661	28,403	0.65	2.3%
	CVP 1462	105	5,589	0.13	1.9%
	NCVP-2	553	50,486	1.16	1.1%
	CVP 1463	292	19,148	0.44	1.5%
Easton Total	6	3,920	116,323	2.67	
Freetown	PVP 8324	4,470	53,142	1.22	8.4%
	PVP 8284	873	4,940	0.11	17.7%
	PVP 8286	4,722	7,900	0.18	59.8%
Freetown Total	3	10,065	65,982	1.51	
Totals	10	15,465 (0.36 Ac.)			

Average depths were not calculated for each of the above pools, so the total volume of fill to vernal pools is not known. The amount of filled surface area in square feet gives an approximate measure of the relative size of disturbance to any given pool. One pool, PVP 8286 in Freetown, would have a majority (59.8 percent) of its area filled (Table 4.14-20).

The impacts to the other pools that would be directly affected range from 1.1 percent to 21.3 percent. Easton has the largest number of pools that would be directly affected (6 pools), while Freetown has the largest amount of fill proposed (10,065 SF). While it is impossible to avoid impacting vernal pools to some degree along the Whittenton Alternative, no direct filling would occur to any vernal pools in Canton, Raynham, Taunton, Berkley, Lakeville, New Bedford, or Fall River.

Figure 4.14-22 shows the distribution of the percentage impacts to vernal pools. Of the 10 vernal pools that are impacted, 6 pools would lose to 10 percent or less of their total area, and 8 pools would lose 20 percent or less of their total area.

Figure 4.14-22 Percent Impacts to Vernal Pools
Whittenton Electric Alternative



These results are based on preliminary design. In the final design phase of the project, additional small impacts may be avoided or minimized through different grading (for example, steepened slopes along the rail line). Additional design efforts would attempt to minimize impacts.

Impacts to vernal pool habitat are defined as impacts to any wetland containing a vernal pool within 100 feet of the boundary of a vernal pool. The loss of vernal pool habitat would affect 27 vernal pools. Table 4.14-21 describes the impacts to vernal pool habitat along the South Coast Rail Whittenton Alternative project corridor. Where pools are in close proximity to one another, the impacted areas of vernal pool habitat overlap. In these cases, the impacts to the affected area of vernal pool habitat are identified as a whole, and the pools that make up each affected area are denoted. As a conservative measure, the entire area of the Hockomock Swamp under the proposed trestle in Easton was included in the calculation of total vernal pool habitat, since this entire area is known to provide good habitat for vernal pool amphibians. No impacts to vernal pool habitat would occur in the area under the trestle.

A total of 20 areas would be impacted, affecting a total of 27 vernal pools. The impacts to pools and habitats that would be directly affected range from 0.3 percent to 24.9 percent. Easton has the largest number of pools that would be affected (13 pools), while Taunton has the largest amount of fill proposed (8,759 SF). While it is impossible to avoid impacting vernal pool habitat to some degree along the Stoughton Alternative, no impacts to vernal pool habitat would occur in Canton, Raynham, Lakeville, or Fall River. Additionally, Stoughton and New Bedford would experience impact to vernal pool habitat

associated with either one or two pools, totaling less than 500 SF in Stoughton and less than 1,300 SF in New Bedford.

Table 4.14-21 Impacts to Vernal Pool Habitat–Whittenton Alternative

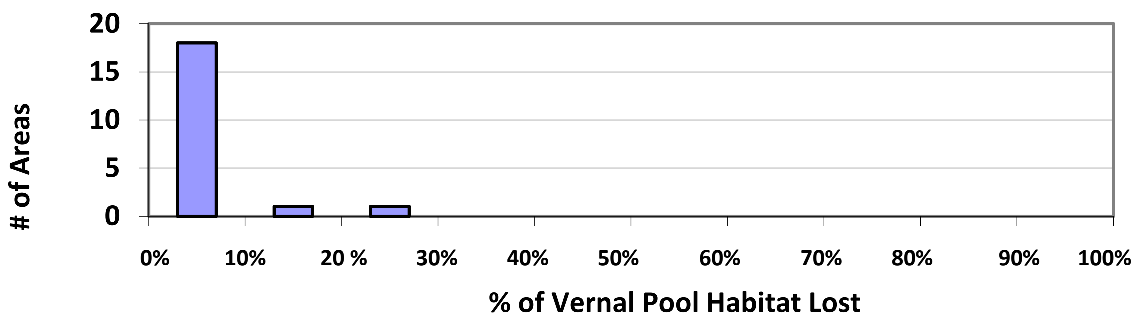
Figure 4.14-23 shows the distribution of the percentage impacts to vernal pool habitat. Of the 20 areas impacted, 17 would lose 10 percent or less of their total vernal pool habitat, and 18 would lose 20 percent or less of their total vernal pool habitat.

Figure 4.14-23 Percent Impacts to Vernal Pool Habitat Whittenton Electric Alternative



Impacts to upland buffer habitat are defined as impacts to any naturally-vegetated upland area within 100 feet of the boundary of a vernal pool. The loss of upland buffer habitat would affect 50 vernal pools. Table 4.14-22 describes the impacts to upland buffer habitat along the South Coast Rail project corridor. Where pools are in close proximity to one another, the impacted areas of upland buffer habitat overlap. In these cases, the analysis identifies the impacts to the affected area of upland buffer habitat as a whole, and denotes which pools make up each affected area. Impacts are calculated for the loss of undeveloped land with natural vegetation that could provide non-breeding and/or migratory habitat for vernal pool amphibians. Therefore impacts calculated to upland buffer habitat did not include any areas of existing rail bed or the surrounding ballast, which were estimated by using a measurement of 10 feet to either side of the track centerline. Impacts to and total areas of upland buffer habitat also did not include any existing developed areas, including buildings and parking areas. Developed areas were estimated by using a land use data layer in the GIS analysis and subtracting any areas of development from impacted areas. No impacts to upland buffer habitat would occur in the area under the proposed trestle in Easton.

A total of 35 areas would be impacted, affecting a total of 50 vernal pools. Impacts to upland buffer habitat would be generally larger than impacts to vernal pool habitat, both in terms of area in square feet and in terms of percentage of available upland buffer habitat associated with each vernal pool or cluster of pools. The majority of impact associated with constructing new tracks and widening existing tracks and berms involves existing uplands. The percentage impacts to upland buffer habitat are therefore greatest in areas where this type of habitat is limited to berms and slopes along large wetlands or wetland complexes. For example, the largest percentage impact to upland buffer habitat is at NHESP 3 in Raynham, which would lose 66.9 percent of its upland buffer habitat. The nearby pool of PVP 20158 is approximately the same distance from the limit of disturbance as NHESP 3, but would lose only 33.0 percent of its upland buffer habitat. This lower percentage is due to the fact that PVP 20158 has additional upland area within 100 feet of the boundary of the pool, whereas the upland area within 100 feet of the boundary of NHESP 3 is mainly limited to the railroad berm.

Table 4.14-22 Impacts to Upland Buffer Habitat–Whittenton Alternative

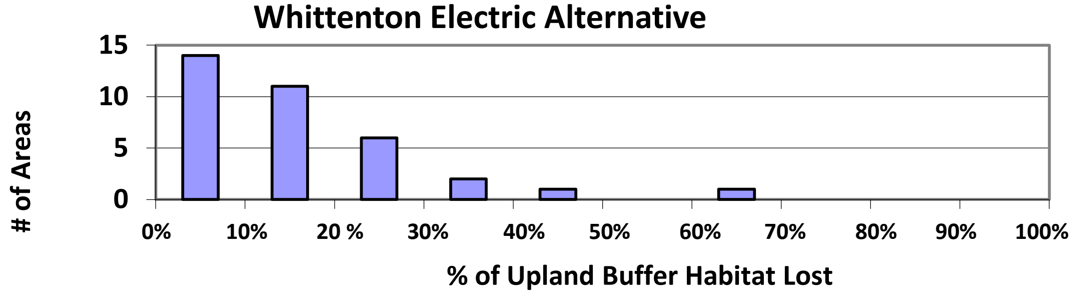
Figure 4.14-24 shows the distribution of the percentage impacts to upland buffer habitat. Of the 35 areas impacted, 14 would lose 10 percent or less of their total upland buffer habitat, and 25 would lose 20 percent or less of their total upland buffer habitat. Ten areas would lose more than 20 percent of their total upland buffer habitat. While impacts to upland buffer habitat can affect the ability of vernal pools to sustain viable populations, all affected pools have additional upland buffer habitat or surrounding upland habitat contiguous to their impacted upland buffer habitat, with the exception of pool NHESP 3.

Figure 4.14-24 Percent Impacts to Upland Buffer Habitat Whittenton Electric Alternative



Impacts to surrounding upland habitat are defined as impacts to any naturally vegetated upland area between 100 and 750 feet of the boundary of a vernal pool. For these pools, point locations were used to represent each pool. The loss of surrounding upland habitat would affect 116 vernal pools. Table 4.14-23 lists the impacts to surrounding upland habitat along the South Coast Rail project corridor.

Where pools are in close proximity to one another, the impacted areas of buffer habitat overlap. In these cases, the impacts to the affected area of surrounding upland habitat are identified as a whole, and the pools that make up each affected area are denoted. Impacts are calculated for the loss of undeveloped land with natural vegetation that could provide non-breeding and/or migratory habitat for vernal pool amphibians. The impacts calculated for surrounding upland habitat did not include any areas of existing rail bed or the surrounding ballast, which were estimated by using a measurement of 10 feet to either side of the track centerline. Impacts to and total areas of surrounding upland habitat also did not include any existing developed areas, including buildings and parking areas. Developed areas were estimated by using a land use data layer in the GIS analysis and subtracting any areas of development from impacted areas. No impacts to surrounding upland habitat would occur in the area under the proposed trestle in Easton. For a single pool surrounded by completely undeveloped area, the total potential surrounding upland habitat would be over 40 acres.

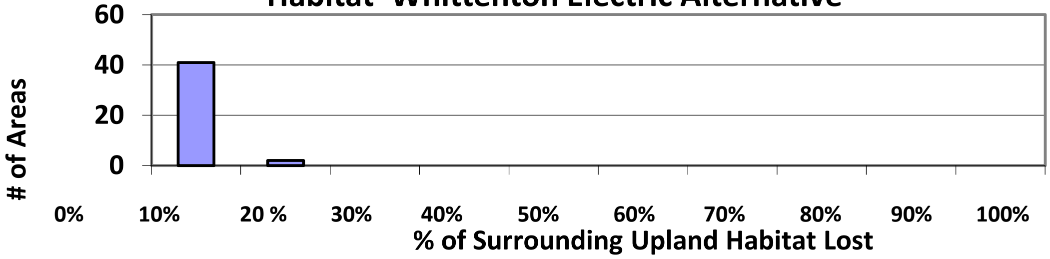
Totals	116	41.61		

A total of 43 areas would be impacted, affecting a total of 116 vernal pools. While impacts to surrounding upland habitat are larger in terms of size than either vernal pool habitat or upland buffer habitat, the overall impacts would be negligible. The large total area of surrounding upland habitat around a given pool, or more often a cluster of pools, tends to ameliorate the impacts to surrounding upland habitat in any one area. The largest percentage impact to surrounding upland habitat is around the pair of pools PVP 20158 and NHESP 3 in Raynham (Figure 4.14-25), which would lose 16.4 percent of their surrounding upland habitat. This impact is due to a combination of significant wetland areas surrounding these two pools as well as large developed areas on the eastern side of the right-of-way. The pair of pools PVP 23784 and CVP 2140 in Stoughton would lose 15.9 percent of their surrounding upland habitat from constructing the North Easton station. Impacts to pools already segregated from the right-of-way by an existing road, such as PVP 4291 in Canton, are unlikely to have any real effect on the pool in question. Conversely, in areas such as that around the pair of pools PVP 23778 and PVP 23779 in Stoughton, impacts are more likely to exclusively affect PVP 23778 due to the separation of PVP 23779 from the right-of-way, again by an existing roadway. Still, the overall effects to either pool would be very small since both have a large contiguous area of surrounding upland habitat around the pool. There are no pools or cluster of pools along the length of the Stoughton Alternative corridor that would have a large percentage of surrounding upland habitat impacted.

Figure 4.14-25 shows the distribution of the percentage impacts to surrounding upland habitat. Of the 43 areas impacted, 41 would lose 10 percent or less of their total surrounding upland habitat, and all 43 would lose less than 20 percent of their total surrounding upland habitat.

Figure 4.14-25 Percent Impacts to Surrounding Upland Habitat Whittenton Electric Alternative



Fragmentation Effects—New fragmentation effects would occur entirely in Easton, Raynham, and Taunton. One additional cluster in Freetown already has PVP 8283 separated from PVPs 8284, 8285, 8286, and 8287 by an existing maintained railway, so additional fragmentation effects are unlikely. Fragmentation is likely to have the largest effects in cases where one pool is newly separated from a cluster, or where a pair of pools is separated to create two single pools, and when the pools are close together (i.e., within 100 feet of one another). This would occur, for example, in Easton, where VP-3 is separated from a cluster of four other pools. In the areas of fragmentation listed in Table 4.14-24, there are no cases where one pool is separated from a pair or cluster without at least some extant surrounding habitat of its own.

0	0.0	0	0.0	5	0.7	17	2.8

Summary of Entire Whittenton Alternative

A total of 116 vernal pools lie along or within 750 feet of the right-of-way of the Whittenton Alternative as a whole. A total of 10 vernal pools would receive direct fill as a result of constructing the Whittenton Alternative, for a total of 0.4 acre of fill. A total of 27 vernal pools would receive fill to vernal pool wetland habitat, for a total of 0.8 acre of fill. The upland buffer habitat of 50 vernal pools would be impacted, for a total of 7.86 acres of impact. The surrounding upland habitat of 116 vernal pools would be impacted, for a total of 41.61 acres of impact. Table 4.14-26 summarizes the direct and indirect impacts to vernal pools along the Whittenton Alternative as a whole.

Table 4.14-26 Vernal Pool Impacts along the Whittenton Alternative

Pools Directly Filled	Amount of Fill (ac)	Pools with VP Wetland Habitat Impacted	Amount of Impact (ac)	Pools with Upland Buffer Habitat Impacted	Amount of Impact (ac)	Pools with Surrounding Upland Habitat Impacted	Amount of Impact (ac)
10	0.36	27	0.8	50	7.86	116	41.61

The following points summarize the impacts by municipality.

- Canton: There are no impacts in Canton. The one vernal pool within 750 feet of the right-of-way is already separated from the right-of-way by an existing roadway.

- Stoughton: Impacts in Stoughton are small. One pool (PVP 23791) would receive direct fill but has large contiguous areas of adjacent vernal pool habitat, upland buffer habitat, and surrounding upland habitat around it. No clusters of pools are present.

- Easton: Six pools would receive direct fill in Easton, although only one (PVP 7222) would lose greater than 20 percent of its area. While upland buffer habitat within 100 feet would be impacted around several pools, in all cases these pools have additional surrounding upland habitat between 100 and 750 feet away. Several clusters and pairs of pools are in close proximity to the right-of-way and would experience fragmentation both of associated habitats and of entire pools from one another. The majority of these clusters and pairs are in close association with one another (i.e., pools are within 100 feet of each other or within 100 feet of another pool in the same cluster).

- Raynham: No fill would occur to any vernal pools or to any vernal pool habitat. One pool (NHESP 3) would lose upland buffer habitat and does not have contiguous adjacent upland habitat nearby. Two clusters of pools would experience fragmentation within 750 feet, plus an additional pair of pools which would experience fragmentation within 100 feet.

- Taunton: No fill would occur to any vernal pools. Five pools would receive impact to vernal pool habitat, with one pool in particular (PVP 25317) losing 24.9 percent of its vernal pool habitat. Taunton also has some of the largest impacts to upland buffer habitat. However, in all cases these pools have additional habitat between 100 and 750 feet away. Taunton also has one cluster of pools that would experience fragmentation within 750 feet.

- Berkley: Impacts in Berkley would be small. No pools would receive direct fill, and impacts to vernal pool habitat are small. Impacts to upland buffer habitat, particularly around PVP 2318 and PVP 2319 are more significant, but these pools have additional surrounding upland habitat. No cases of fragmentation between pools occur in Berkley.

- Lakeville: Impacts in Lakeville are very small. Few vernal pools exist along the right-of-way and no pools would receive direct fill. Impacts to other associated habitats are also small, and there are no cases of fragmentation between pools.

- Freetown: One pool (PVP 8286) in Freetown would receive fill to a majority of its area, and would also receive an impact greater than 25 percent to both vernal pool habitat and upland buffer habitat. The nearby pool of PVP 8284 would also receive direct fill as well as impacts to vernal pool habitat and upland buffer habitat. In both cases these pools have additional habitat between 100 and 750 feet away. The remainder of the pools in Freetown do not receive large impacts.

- New Bedford: Impacts in New Bedford would be very small. Few pools exist along the right-of-way. No pools would receive direct impacts, and impacts to other associated habitats are small, with exception of one large impact to the upland buffer habitat of CVP 2647. However this pool has large unfragmented areas of additional surrounding upland habitat.

- Fall River: There are no impacts in Fall River.
- Overall, impacts to vernal pools along the South Coast Rail Whittenton Alternative project corridor are small and are not likely to compromise the functions of pools or communities of pools along the route. One vernal pool would lose a majority of its area (PVP 8286 in Freetown). Of the remaining pools, no pool or group of pools would lose a majority of its vernal pool habitat, upland buffer habitat or supporting upland habitat. Additionally, pools that lose areas of associated habitats have additional, larger contiguous areas of these habitats adjacent to them, with the exception of NHESP 3 in Raynham.

Fish and Wildlife Crossings—A detailed inventory of bridges and culverts was conducted to identify the location, condition, and function of each structure. Dimensions, construction materials, and railroad bed characteristics were recorded. For this biodiversity assessment, the subset of bridges and culverts with potential ecological value was determined by reviewing wetland mapping, surrounding land use (as visible in aerial photographs), and other ecological setting features (as modeled by CAPS[72]) of the complete bridge and culvert inventory. The CAPS model output indicates areas with a high (over 50 percent) Index of Ecological Integrity (IEI). No areas with a high IEI exist along the Whittenton Branch.

Most of the culverts along the Whittenton Branch currently have limited ecological function. Almost all of culverts under the Whittenton Branch right-of-way are at least 50 feet in length; the use of these culverts by wildlife for crossing the right-of-way is unlikely. The culvert connecting Wetlands RWB 02 and RWB 02.1 in Raynham is the largest culvert along the Whittenton Branch, measuring four feet wide and nearly 5 feet high, and approximately 35 feet in length. This culvert is large enough and allows enough daylight to penetrate to allow for animal passage under the right-of-way. This culvert appears to carry little water from drainage ditches along Wetland RWB-02.1 and is dry for long portions of the year. However, most of the land on the eastern side of this culvert is residential, impacting the usefulness of this culvert. At least one culvert along the right-of-way (between Wetlands TWB 09 and TWB 10) is mostly collapsed or buried, and has a reduced hydrologic function and little or no ecological function.

The bridge and most of the culverts along the Whittenton Branch alignment will be replaced to meet engineering requirements for operation of the South Coast Rail. The track design is conceptual at this stage but takes into consideration operational and safety requirements as well as the gentle elevation change requirements of a fixed guideway transit system. Railroad track elevation changes and curves must be gradual to accommodate the design requirements for a safe high speed train track. Additionally, the railroad bed must meet certain width and depth specifications (depending on the nature of the underlying ground surface) to provide proper track support and ballast drainage.

Piers or pilings supporting the existing Mill River bridge will be replaced by a single pier at the center of a two-span structure, minimizing impacts to stream hydrology and fish habitat. Existing piles would be removed and one new cast-in-place concrete pier would be constructed in the center of the span. New cast-in-place concrete abutments would be constructed behind the existing abutments, which would then be partially removed to an elevation equal to the river's average seasonal high water elevation to improve wildlife passage.

Other Important Habitat Areas—The Whittenton Alternative crosses two large undeveloped areas that provide potentially important wildlife habitat. Near the north end of the Whittenton Branch is a large

[72] UMass Extension. 2011. CAPS Index of Ecological Integrity. http://umasscaps.org/.

undeveloped forested upland and wetland complex that includes Prospect Hill Pond. Near its south end, the Whittenton Branch crosses a large undeveloped wetland and upland complex just north of Whittenton Junction. The former right-of-way through these areas is currently used as a recreational trail for ATVs, and as an access road for a gravel pit in the southern portion. Restoring the track would create a barrier to the movement of small vertebrates, fragmenting habitat and potentially affecting genetic diversity and long-term persistence of some populations. The overhead catenary system of poles and wires would increase the width of the canopy gap, potentially affecting bird movement

Indirect Impacts of the Whittenton Electric Alternative: Stoughton/Whittenton Rail Segment

The analysis of indirect impacts evaluates the effects of the Whittenton Electric Alternative on key elements of biodiversity. Where the Whittenton Alternative's impacts on natural communities would occur entirely along the edge of, existing active rail lines, indirect impacts to natural communities, wildlife or fisheries are anticipated to be minor and restricted to the edges of these communities. The Whittenton Alternative also has the potential to cause larger indirect effects to natural communities where it would reconstruct an out-of-service rail line, particularly along the Stoughton Line south of Foundry Street in Easton, and along the Whittenton Branch from Raynham Junction to Whittenton Junction in Taunton.

Converting the out-of-service railroad alignment to active rail would increase habitat fragmentation in two areas: the Prospect Pond area and the southernmost section of the Whittenton Branch between the quarry access road and Whittenton Junction. None of these areas are mapped as Important Wildlife Habitat by DEP. Although the proposed project would not substantially increase or create a new canopy gap, and therefore would not change the existing forest interior conditions, there would be increased train activity and noise, and the raised track would impede movement of small vertebrates. Reconstructing the railroad track system at the southernmost end of the Whittenton Branch, between the quarry access road and Whittenton Junction, would increase the width of the canopy gap over the railbed to 30 feet wide in areas with single track. Although this would increase the canopy gap and create a partial barrier to vertebrate movement the adjacent areas would continue to provide moderate sized forest blocks and would sustain wildlife habitat.

Vegetation—The information and analyses presented for the Stoughton Alternative are equally applicable to this section of the Whittenton Alternative.

Habitat Fragmentation and Noise Impacts—The information and analyses presented for the Stoughton Alternative are equally applicable to this section of the Whittenton Alternative

Findings of CAPS Model—The CAPS analysis showed that the Whittenton Alternative would result in the loss of IEI units, as shown in Table 4.14-27. Not unexpectedly, the majority of the loss of connectivity (64 percent) would occur north of Weir Junction, where there is no existing rail traffic. The Hockomock trestle would have less impact on connectedness than an at-grade track as it would present less of a barrier to wildlife movement.

Table 4.14-27 Loss of Ecological Integrity–Whittenton Alternative[1]

Option	Total Loss	Loss North of Weir Junction
With Trestle	484.6	312.1
Without Trestle	492.0	319.5

1 Measured in Index of Ecological Integrity Units

Whittenton Diesel Alternative

The Whittenton Diesel Alternative would generally have the same effects on biodiversity as the Whittenton Electric Alternative. However, there would be no overhead catenary system and consequently a slightly lower impact on continuity of forest bird habitats. Because there would be no power substations, the Whittenton Diesel Alternative would result in 2.24 acres less habitat loss overall compared to the Whittenton Electric Alternative.

Stations

Station locations have remained as shown in the DEIS/DEIR, with the exception of the Stoughton Station, which was relocated to eliminate conflicts with traffic in Stoughton Center and to support downtown revitalization efforts. Additionally, the Downtown Taunton Station has been replaced by the Dana Street Station, which would be located on the east side of the railroad between the alignment and Dana Street.

Station layout, parking, grading, and drainage designs have been advanced since completion of the DEIS/DEIR at the North Easton, Easton Village, Raynham Park, Taunton, Taunton Depot, and Freetown locations. The majority of the proposed stations would be in developed areas and would not affect natural habitats or biodiversity. These stations (Battleship Cove, Easton Village, Fall River Depot, King's Highway, Taunton, Dana Street, and Whale's Tooth) are not included in this analysis. Reconstructing existing commuter rail stations (Canton, Canton Junction, Mansfield, and Stoughton) would also not affect biodiversity. The remaining stations (Taunton Depot, Freetown, North Easton, and Raynham Park) are discussed in this section.

Taunton Depot—Taunton Depot Station (Figure 4.14-26) would be a new station constructed on the Attleboro Secondary in Taunton and would serve all of the rail alternatives. The proposed station site is in a previously-disturbed area and is not within a large block of undisturbed habitat. Impacts to biodiversity would be negligible. Approximately 6.01 acres of habitat would be lost, largely cleared land (disturbed habitat).

Freetown—Freetown Station (Figure 4.14-27) would be a new train or bus station constructed to serve the Fall River Secondary for all rail alternatives. The proposed station site may fragment an already disturbed corridor of forest and fields that extends from the Copicut Road/Route 24 intersection to South Main Street, along the west side of the active freight tracks. While there is development along the frontage of South Main Street, this development has also resulted in the clearing and grading of adjacent land surrounding the development. Constructing the proposed station may fragment this area and reduce habitat value of the remaining portions. Approximately 4.33 acres of habitat would be lost, largely upland shrub habitat.

North Easton—North Easton Station (Figure 4.14-28) would be a new station constructed on the Easton/Stoughton town line. The station is proposed on the east side of the Stoughton Line right-of-way in an area partially consisting of a heavily disturbed, mostly unvegetated area, and partially within a mixed forested area. The station would be directly east of the Stoughton Memorial Conservation Lands, a large and important habitat area. Approximately 8.40 acres of habitat would be lost, largely upland forest and shrub land. Impacts to biodiversity are expected to be minimal and will result in increased edge effects surrounding the station. Minor edge effects on the adjacent conservation land could occur as a result of noise, lights and activity at the station. No mapped rare species habitats occur in proximity to the station.

Raynham Park—Raynham Park Station (Figure 4.14-29) would be a new station constructed along the Stoughton Line that would serve the Stoughton and Whittenton Alternatives. It would be constructed in a disturbed area adjacent to the north buildings of the Raynham Park. The area is mostly paved and has been previously altered. Stormwater controls will be implemented into the project design to improve the water quality of runoff leaving the site and entering the receiving waters, which flow into the Hockomock Swamp ACEC.

Effects to biodiversity are expected to be minimal from construction of this station because the station will be constructed in disturbed upland that is mostly paved. Approximately 3.25 acres of habitat would be lost, largely wooded uplands.

Layover Facilities

One of the proposed layover sites (Weaver's Cove East) would affect undeveloped land with the potential to support biodiversity and is described below. The Wamsutta site (Figure 4.14-3e) proposed along the New Bedford Main line and the mid-day layover facility planned for the Boston area would be entirely within previously developed land and do not support biodiversity.

Fall River–Weaver's Cove East—The proposed Weaver's Cove East layover facility (Figure 4.14-4b), would be located east of the Fall River Secondary in a previously-disturbed and developed area, and approximately 100 feet from the Taunton River. It is partially a brownfield site that is cleared (some foundations and roadways remain) but is mostly undeveloped. Constructing a layover facility at this location would result in the loss of 9.12 acres of plant communities, primarily upland forest and cleared land.

4.14.3.3 Temporary Construction-Period Impacts

Constructing the South Coast Rail alternatives could result in temporary, short-term impacts to biodiversity during the construction period.

Temporary Impacts

Temporary impacts include short-term disturbances to biological resources during construction that would cease once construction activities are complete. This may include, but is not limited to, installing erosion controls, establishing work areas, or installing temporary structures at stream crossings.

Potential short-term construction related impacts may include impaired ground and surface water due to sedimentation in stormwater runoff or accidental spills; displaced wildlife due to physical disturbance and noise; and plant and animal injury or death from construction equipment and activities.

Sediment discharges to surface water bodies could increase turbidity, potentially clogging the gills or feeding apparatus of aquatic organisms. Sediment accumulation on aquatic substrates could affect fish breeding habitat, or could reduce the growth of aquatic plants. Sediment discharges to vernal pools could affect the survival of aquatic larvae.

Temporary impacts to water quality during construction would be reduced or eliminated through the use of appropriate best management practices, documented in the Stormwater Pollution Prevention Plan (SWPPP) prepared and implemented in accordance with the requirements of the NPDES Construction Permit program. BMPs for erosion control would include perimeter sedimentation controls (silt fence, haybales, filter berms, siltation booms), temporary stabilization of disturbed areas, and

temporary siltation basins where appropriate. The proposed project is not anticipated to result in long-term adverse effects to water quality, as the proposed design will treat runoff generated by the track prior to discharge, and will comply with all of the Massachusetts Stormwater Standards for work at the proposed stations. Compliance with the standards ensures that the proposed stations will not affect groundwater discharge that supports base streamflows, as well as protecting water quality. Following construction all construction areas will be permanently stabilized with pavement, railroad ballast, or vegetation, and will not change siltation in any waterway. None of the proposed stations would discharge runoff to a waterway.

The proposed project will not result in the loss of riparian habitat. The rehabilitation of existing commuter rail and freight rail lines will not affect riparian habitat. The restoration of out-of-service rail right-of-way through Stoughton, Easton, Raynham and Taunton will likely require that vegetation within the right-of-way, adjacent to waterways, be removed to the proposed width of the ballast (ranging from 25 to 40 feet, depending on the topography and the number of tracks). This will remove overhanging vegetation from short segments (25 to 40 feet) of Whitman Brook, Black Brook, and Pine Swamp Brook, but is not anticipated to change water temperatures as the overhanging vegetation will be replaced by a bridge, maintaining shade over the banks and channel.

The only stocked trout water is Rattlesnake Brook. No work is proposed within or adjacent to the waterway at this location, as Rattlesnake Brook is below Route 24.

Erosion and sedimentation controls along the perimeter of the railroad corridor may affect the ability of small vertebrates (amphibians, turtles, small rodents) to cross the railroad right-of-way during construction. This barrier effect would be temporary and would cease when erosion controls were removed. Coffer dams or sandbags used to allow bridges or culverts to be replaced could affect the movement of fish if the entire waterway were blocked.

Construction noise and construction activity could displace wildlife from areas adjacent to the rail or highway corridor. This impact would be temporary, and wildlife is expected to return to areas near the rail or highway corridor once construction activities cease.

Temporary Impacts–Stoughton Alternatives

The Stoughton Alternatives would have temporary impacts to terrestrial and aquatic wildlife communities along the Stoughton Line, New Bedford Main Line (north of Route 140) and the Fall River Secondary (north of the developed center of Fall River). In the absence of mitigation, these impacts could be most severe along undeveloped areas with important aquatic habitats (the Hockomock Swamp, Pine Swamp, the New Bedford Main Line through the Assonet Cedar Swamp, and the New Bedford Main Line at the boundary of the Acushnet Cedar Swamp).

Temporary Impacts–Whittenton Alternatives

The Whittenton Alternatives would have temporary impacts to terrestrial and aquatic wildlife communities along the Stoughton Line, the Whittenton Branch, the Attleboro Secondary (except through the developed center of Taunton), the New Bedford Main Line (north of Route 140) and the Fall River Secondary (north of the developed center of Fall River). In the absence of mitigation, these impacts could be most severe along undeveloped areas with important aquatic habitats (the Hockomock Swamp, Prospect Hill Pond, the New Bedford Main Line through the Assonet Cedar Swamp, and the New Bedford Main Line at the boundary of the Acushnet Cedar Swamp).

Mitigation for Construction-Period Impacts

Construction impacts to aquatic resources will be mitigated by the appropriate use of erosion and sedimentation controls to minimize and eliminate sedimentation of wetlands and waterways. Erosion and sedimentation controls would be installed before construction begins, properly maintained, and removed after disturbed areas have stabilized. A Stormwater Pollution Prevention Plan would be developed and implemented as required by the NPDES Construction General Permit. Erosion controls would be monitored and maintained throughout the construction period, and removed after disturbed areas have stabilized.

Timing of construction may affect the extent of impacts to fish and wildlife species. Disturbance of habitat during the breeding season is likely to have greater short-term or individual effects on reproductive success, though short-term effects are not likely to have long-term repercussions unless the species population is already unstable. To avoid potential short-term effects to breeding wildlife, all efforts will be taken to avoid construction during the breeding season (March through June) in Hockomock and Pine Swamps, and in areas where movement of rare species is a concern. In all cases construction will be limited to normal daylight hours. Additional measures, such as “turtle gates,” may be used in sensitive areas to allow small vertebrates to cross the right-of-way during critical breeding periods.

The vast majority of areas disturbed for construction (extending 14 feet to each side of the track centerline, for a total width of 28 feet for single track and 42 feet for double track) will be surfaced with ballast and will be within the area where vegetation must be managed for railroad safety. These areas will not be allowed to revegetate. Disturbed areas outside of the trackbed would be seeded with an appropriate stabilization seed mix using native species. These seeded areas would be expected to revegetate within one growing season.

4.14.3.4 CAPS Analysis Impacts

The results of the CAPS analysis show that the differences among the alternatives are obscured to some degree by the large sections of the routes that are common to all the alternatives. To better highlight the differences among the alternatives, the analysis computed the IEI for each alternative only for those sections that were not shared among all alternatives (i.e., excluding the Southern Triangle south of Weir Junction and tracks north of Canton Junction) (Table 4.14-28).

Table 4.14-28 Loss of Index of Ecological Integrity Units

Alternative	Direct Loss	Indirect Loss	Total Loss	Total Loss Excluding Common Elements
Stoughton with Trestle	17.6	456.9	474.5	302.0
Stoughton without Trestle	17.7	464.1	481.8	309.3
Whittenton with Trestle	17.6	467.1	484.6	312.1
Whittenton without Trestle	17.7	474.3	492.0	319.5

This analysis shows that reconstructing the tracks and re-introducing commuter rail service on the Southern Triangle (the New Bedford Main Line from Weir Junction to Whale's Tooth, and the Fall River Secondary from Myricks Junction to Battleship Cove, including stations in undeveloped areas at Taunton Depot and Freetown) would result in a decrease of 172.5 IEI Units. This represents 36 percent of the total loss for the Stoughton (with trestle) Alternative or the Whittenton Alternatives. Figure 4.14-30 shows the effect of the Southern Triangle on IEI Units. Within the Southern Triangle there is no change in connectedness among the different rail alternatives.

The Stoughton (Figures 4.14-31 and 4.14-32) and Whittenton (Figures 4.14-33 and 4.14-34) Alternatives are similar, with the Whittenton Alternatives showing a slightly higher loss of IEI Units. The trestle through the Hockomock Swamp would reduce the biodiversity effects for either the Stoughton or Whittenton Alternatives by 7 IEI Units.

The CAPS analysis shows that three metrics, connectedness, similarity, and traffic intensity, have the greatest effect on the loss of IEI Units. Connectedness, with its broader scale and integration of landscape resistance, is the most relevant metric. The change in connectedness is shown by the different color tones (darker areas = higher loss). Implementation of the rail alternatives would result in no change in connectedness within the Southern Triangle among the different rail alternatives. The higher rates of train traffic on the New Bedford Main Line and the Fall River Secondary would result in a slight decrease in connectivity through the Assonet Cedar Swamp area in Lakeville when compared to the existing connectedness (Figure 4.14-35 and Figure 4.14-36).

The Stoughton and Whittenton Alternatives would reduce connectivity in the Hockomock Swamp with a gradient ranging from major impacts close to the rail line to negligible impacts at greater distances, compared to the existing connectedness (Figure 4.14-37). Without a trestle (Figure 4.14-38), these alternatives would result in substantial losses in connectivity in the Hockomock Swamp east of the rail line, between the Raynham dog track and Foundry Street and between the rail line and Route 138, and in some areas west of the rail line. Moderate impacts would extend through much of the Hockomock, including areas east of Route 138. These impacts would be reduced by the trestle (Figure 4.14-39), with major losses restricted to a smaller area east of the rail line and north of the dog track. Impacts would also extend over a smaller area than the "no-trestle" option.

The restoration of commuter rail through Pine Swamp in Raynham, for the Stoughton Alternatives, would result in a decrease in connectivity throughout the swamp when compared to the existing connectedness (Figure 4.14-40). The effect is moderate, with some higher areas of decrease occurring west of the rail line (Figure 4.14-41).

Relevance of the CAPS Model to Mitigation and Limitations of CAPS Analysis

In November 2011 the UMass Extension Center for Agriculture published two sets of town maps based on CAPS. In conjunction with DEP, UMass produced Important Wildlife Habitat maps. In cooperation with the applicant and the Federal Highway Administration (FHWA), UMass produced IEI maps showing the 50 percent of the landscape with the highest IEI values and color-coded by habitat type (forests, shrublands, freshwater wetlands and aquatic habitats). These maps show the existing conditions and are useful in visualizing the existing important biodiversity areas. In addition, these maps are useful in identifying areas where biodiversity mitigation may be of the most value.

Because CAPS is a coarse-filter analysis based on the ecological and geospatial information available in 30 x 30 meter squares, it is not sufficiently fine-grained to evaluate the effects of specific mitigation

measures such as improved culverts. The CAPS input data for stream crossings includes only three character-states: no obstruction, bridge, or culvert. Even if more fine-grained gradations of culverts were added to the data set (i.e., culverts smaller than 24 inches, culverts 24 to 48 inches, culverts wider than 48 inches) the likely change in IEI values would be negligible, given that IEI values are in the scale of acres.

CAPS is also not an appropriate tool for evaluating the effects of mitigation measures such as wetland creation, wetland restoration, or habitat protection/preservation. Because the model assesses landscape-level changes in physical conditions, a change from unprotected land to protected land does not change the IEI status of a particular area.

In addition, CAPS as applied to this project does not account for the effects of the existing railroad grade on overall landscape condition. The railroad grade has had a demonstrable impact on fragmentation, as witnessed by the fact that Atlantic white cedar habitat is confined to the west side of the right-of-way, whereas the east side is nearly monotypic red maple. This attests to the effects of the grade on hydrology and the resultant vegetation that has emerged on either side over the past century. In addition, although current use of the corridor by pedestrians and ATVs is by no means as intense as a highway with motor vehicles, these uses do have a measurable impact on the ecology of the system – most notably through ATVs leaving the corridor and crossing through vernal pools and the Atlantic white cedar swamp, on circuitous or serpentine routes. These frequent uses of the existing grade itself also serve to maintain at least a partial canopy gap, particularly north of the existing power line and also adjacent to portions of the existing Raynham Park racetrack. The CAPS analysis does not account for these effects and instead assumes that Hockomock Swamp in its current condition is one unfragmented, continuous, uniformly intact habitat. Thus while it provides a measure of the potential benefits of the trestle, CAPS seemingly overestimates and overstates the existing ecological integrity of Hockomock and Pine swamps, and thus likewise overestimates the effects of South Coast Rail on ecological integrity.

4.14.3.5 Summary of Impacts by Alternative

Each of the alternatives evaluated in this chapter would have direct effects on biodiversity associated with the loss of natural, vegetated areas, particularly wetlands or areas within important wildlife habitats. These alternatives could also have indirect impacts, particularly from constructing new tracks or restoring abandoned or out-of-service rights-of-way. These alternatives also offer opportunities to improve wildlife passage and reduce fragmentation by reconstructing existing bridges or culverts.

No-Build (Enhanced Bus) Alternative

The No-Build Alternative would not impact natural communities or biodiversity.

Stoughton Electric Alternative

The Stoughton Electric Alternative includes improvements to existing active freight or rail lines from Canton Junction to Stoughton Station, and on the two Southern Triangle segments (the Fall River Secondary and New Bedford Main Line), as well as restoring out-of-service rail line from Stoughton Station to Longmeadow Street in Taunton. This alternative would include constructing a trestle through part of the Hockomock Swamp to reduce impacts to wetlands, biodiversity, and rare species.

Areas of concern for biodiversity impacts (north of the Southern Triangle) have been identified as the Bird Street Conservation Area in Stoughton, the Hockomock Swamp, and Pine Swamp. Potential impacts could include direct loss of habitat, fragmentation (either by creating a canopy gap or reducing the

ability of wildlife species, including state-listed rare species, to cross the rail bed), introduction of invasive species, or increased noise.

As shown in Table 4.14-29, the Stoughton Electric Alternative would result in the loss of approximately 182.27 acres of upland habitat and 12.3 acres of wetland habitat. This segment of the Stoughton Electric Alternative would increase habitat fragmentation (the existing rail bed, although out-of-service, has fragmented habitats and acts as a barrier to some organisms) within the Hockomock Swamp ACEC and the Pine Swamp. This barrier may affect several vernal pool complexes.

Stoughton Diesel Alternative

The Stoughton Diesel Alternative would result in similar impacts to biodiversity as the Stoughton Electric Alternative. Because it would not require electrical power substations, the Stoughton Diesel Alternative would require 3.49 acres less upland habitat loss, and 0.01 acre less wetland habitat loss when compared to the Stoughton Electric Alternative.

Whittenton Electric Alternative

The Whittenton Alternative includes improvements to existing active freight or rail lines from Canton Junction to Stoughton Station, along the Attleboro Secondary through downtown Taunton, and on the two Southern Triangle segments (the Fall River Secondary and New Bedford Main Line), as well as restoring out-of-service rail line from Stoughton Station to Raynham Junction on the Stoughton Line and along the out-of-service Whittenton Branch in Raynham and Taunton. This alternative would include constructing a trestle through part of the Hockomock Swamp to reduce impacts to wetlands, biodiversity, and rare species.

Table 4.14-29 Stoughton Electric Alternative–Summary of Impacts

	Upland Habitat Loss	Wetland Habitat Loss	Fragmentation[1]	Vernal Pool Habitat Loss	Loss of Supporting Vernal Pool Upland Habitat[2]
Total	182.27	12.3	Yes	1.43	43.40

1 Stoughton Line north of Weir Junction to Raynham Junction.
2 Loss of supporting vernal pool upland habitat includes loss of buffer habitat defined as loss of forested wetland within 100 feet of VHP, and includes loss of upland habitat defined as upland habitat loss calculated for forested upland habitat between 100 and 750 feet of a vernal pool.

Areas subject to biodiversity impacts (north of the Southern Triangle) have been identified as the Hockomock Swamp, and the Bird Street Conservation Area in Stoughton. Potential impacts could include direct loss of habitat, fragmentation (either by creating a canopy gap or reducing the ability of wildlife species, including state-listed rare species, to cross the rail bed), introduction of invasive species, or increased noise.

As shown in Table 4.14-30, the Whittenton Electric Alternative would result in the loss of approximately 187.98 acres of upland habitat and 11.2 acres of wetland habitat. This segment of the Whittenton Electric Alternative would increase habitat fragmentation (the existing rail bed, although out-of-service, has fragmented habitats and acts as a barrier to some organisms) within the Hockomock Swamp ACEC. This barrier may affect several vernal pool complexes.

The Hockomock Swamp ACEC is the only ACEC that would be impacted by the Whittenton Alternatives. Approximately 0.14 acre of vernal pool habitat, 2.31 acres of buffer habitat, and 6.12 acres of upland habitat would be impacted within the Hockomock Swamp ACEC.

Table 4.14-30 Whittenton Electric Alternative–Summary of Impacts

	Upland Habitat Loss	Wetland Habitat Loss	Fragmentation[1]	Vernal Pool Habitat Loss	Loss of Supporting Vernal Pool Upland Habitat[2]	Other
Total	187.98	11.2	Yes	0.8	41.61	—

Stoughton Line north of Weir Junction to Raynham Junction.

1 Includes impacts (fill) to vernal pools and to any wetland area within 100 feet of the boundary of a vernal pool, where the pool is within a wetland.

2 Loss of supporting vernal pool upland habitat includes loss of buffer habitat defined as loss of forested wetland within 100 feet of VHP, and includes loss of upland habitat defined as upland habitat loss calculated for forested upland habitat between 100 and 750 feet of a vernal pool.

Whittenton Diesel Alternative

The Whittenton Diesel Alternative would result in similar impacts to biodiversity as the Whittenton Electric Alternative. Because it would not require power substations, the Whittenton Diesel Alternative would require 4.11 acres less upland habitat loss, and 0.01 acre less wetland habitat loss, when compared to the Whittenton Electric Alternative.

The CAPS analysis evaluated the loss of IEI units (Index of Ecological Integrity) as a means of assessing the biodiversity effects of the alternatives. As shown in Table 4.14-31, the analysis compared the Stoughton Alternative north of Weir Junction with the Whittenton Alternative north of Weir Junction. The Whittenton Alternative would result in the direct loss of 0.1 IEI Unit more than the Stoughton Alternative, and would have a total indirect loss of IEI Units 7.2 more than the Stoughton Alternative. The CAPS analysis indicates that the Whittenton Alternative would have a greater effect on habitat connectivity and biodiversity than the Stoughton Alternative, in the segment that includes Pine Swamp.

Table 4.14-31 Loss of Index of Ecological Integrity Units

Segment	Excluding Common Route Units	Total Direct	Total Indirect
Stoughton Alternative (with trestle)	302.0	17.6	456.9
Whittenton Alternative (with trestle)	309.3	17.7	464.1
Difference	7.3	0.1	7.2

Comparison of Alternatives

A comparison of the effects of the South Coast Rail alternatives on biological diversity (plant, wildlife and fish communities and habitats) is shown in Table 4.14-32. As discussed in detail in Section 4.14.3.2 of this chapter, all Build Alternatives would result in the loss of upland habitat, wetland habitat, and vernal pool habitat (including direct and indirect impacts to vernal pools as well as supporting upland habitat used by vernal pool amphibians). All Build Alternatives, would result in habitat fragmentation and would create or exacerbate a barrier to wildlife movement.

Table 4.14-32 Summary of Environmental Consequences

Alternative	Upland Habitat Loss	Wetland Habitat Loss	Fragmentation	Vernal Pool Habitat Loss	Loss of Supporting Vernal Pool Upland Habitat
Stoughton Electric	182.27	12.3	Yes	1.43	43.40
Stoughton Diesel	178.78	12.3	Yes	1.43	43.40
Whittenton Electric	187.98	11.2	Yes	0.8	41.61
Whittenton Diesel	183.87	11.2	Yes	0.8	41.61

Stoughton Line north of Weir Junction to Raynham Junction.

Notes: Includes impacts (fill) to vernal pools and to any wetland area within 100 feet of the boundary of a vernal pool, where the pool is within a wetland.
Loss of supporting vernal pool upland habitat includes loss of buffer habitat defined as loss of forested wetland within 100 feet of VHP, and includes loss of upland habitat defined as upland habitat loss calculated for forested upland habitat between 100 and 750 feet of a vernal pool.
Diesel Alternative would result in 0.03 acre less wetland habitat loss for both the Stoughton and Whittenton Alternatives.

The Whittenton Alternative would have less wetland loss (11.2), and the least impacts to vernal pool wetland habitat (0.8 acre).

Each of the rail alternatives would result in habitat fragmentation and associated indirect effects on natural communities. The Stoughton Alternatives would fragment wetland and upland communities, particularly through the Hockomock Swamp and Pine Swamp, although the barrier effect would be reduced by constructing a trestle. The Whittenton Alternatives would fragment wetland and upland communities, particularly through the Hockomock Swamp and along the Whittenton Branch, although the barrier effect would be reduced by constructing a trestle in the Hockomock Swamp.

4.14.3.6 Mitigation

This section discusses strategies and measures that could be used to mitigate for impacts to biological diversity. Although there are no state or federal regulatory programs that establish mitigation requirements for impacts to biological diversity, the discussion below considers whether impacts to biodiversity could be avoided or minimized, and whether mitigation measures could be incorporated into the alternatives to mitigate for unavoidable impacts. No mitigation is proposed specifically for impacts to non-regulated plant, wildlife or fish communities. Mitigation for impacts to regulated resources such as wetlands, waterways, and threatened and endangered species would incorporate measures to protect and enhance the biodiversity of these resources.

Avoidance

Avoidance evaluates whether there are alternatives, or modifications to alternatives, that would avoid impacts to biodiversity.

No-Build Alternative

The No-Build Alternative, because it does not require any new construction, would avoid any impacts to plant communities, wildlife, or fisheries.

Stoughton Alternatives

The Stoughton Electric and Stoughton Diesel Alternatives require several construction elements that would impact plant communities, wildlife, or aquatic communities. Restoring the out-of-service Stoughton Line will adversely affect plant and wildlife communities, particularly in the Hockomock Swamp and Pine Swamp. The Stoughton Alternatives use the existing New Bedford Main Line and Fall River Secondary to reduce impacts to natural communities. Minor losses of vegetation and wildlife habitat along the edges of these existing rail lines cannot be avoided if the tracks are upgraded to current standards.

Whittenton Alternatives

The Whittenton Electric and Whittenton Diesel Alternatives require several construction elements that would impact plant communities, wildlife, or aquatic communities. Restoring the out-of-service Stoughton Line and Whittenton Branch will adversely affect plant and wildlife communities, particularly within the Hockomock Swamp. The Whittenton Alternatives use the existing Attleboro Secondary, New Bedford Main Line and Fall River Secondary to reduce impacts to natural communities. Minor losses of vegetation and wildlife habitat along the edges of these existing rail lines cannot be avoided if the tracks are upgraded to current standards.

Station Sites and Layover Facility Sites

Station and layover facility sites were selected to avoid impacts to sensitive biological resources, as documented in Chapter 3. Station and layover sites were placed in previously-developed upland areas wherever feasible. Where a previously-developed site was not available, these facilities were sited in upland areas that did not contain sensitive or uncommon plant communities, mapped rare species habitats, or vernal pools. Stations and layovers were located to avoid construction in unfragmented forest habitats.

Minimization

Where avoidance is not possible, impacts would be minimized to the best extent practicable. Measures to minimize direct and indirect impacts to biodiversity (plant, wildlife, and aquatic communities) will be developed as part of the mitigation for impacts to wetlands, threatened and endangered species, and water resources. In addition to other minimization measures not yet identified, these measures would include:

- Adjusting the grading to reduce the loss of plant or wildlife communities.
- Evaluating all culverts to determine whether replacing a culvert could adversely impact, or benefit, biodiversity.
- Using retaining walls to reduce the loss of unique natural communities.
- Replanting disturbed areas.
- Developing and implementing an invasive species control plan.

The Stoughton and Whittenton Alternatives were designed with specific measures to minimize habitat fragmentation. Both the Stoughton and Whittenton Alternatives include the proposed Hockomock

trestle, extending for approximately 8,500 feet. The trestle would maintain habitat connectivity for small terrestrial and aquatic vertebrates and other wildlife and thus minimize impacts to biodiversity. The Whittenton Alternative would further minimize impacts to biodiversity by avoiding the Pine Swamp area in Raynham, which would be crossed by the Stoughton Alternative.

Specific Mitigation Measures

Measures to mitigate for unavoidable direct and indirect impacts to biodiversity (plant, wildlife, and aquatic communities) will be developed for the least environmentally damaging practicable alternative (LEDPA). Specific measures to mitigate for impacts to state-listed rare species are described in Chapter 4.15, *Threatened and Endangered Species.* These measures are anticipated to benefit a wide range of species in addition to the targeted species (Blanding's turtle, eastern box turtle, blue-spotted salamander). The wildlife crossings constructed along the MBTA's Greenbush Line have been shown to be used by numerous species, reducing the barrier effect of the rail.[73] Specific measures to mitigate for impacts to wetlands would be designed to enhance the ability of wetlands to provide wildlife habitat, protect fisheries, and provide aquatic habitat. In addition to other mitigation measures not yet identified, these measures could include:

- Constructing wildlife crossings.
- Enhancing or replacing habitat.
- Preserving important habitat areas.
- Developing construction phasing schedules to protect species.

Each of the alternatives presents opportunities to improve wildlife habitat, particularly by reconstructing existing culverts or bridges to improve wildlife or fish passage and reduce fragmentation. In addition, the CAPs model can be used as a tool to contribute to the optimization of mitigation by enhancing the area of land with high IEI values and connectedness.

Fisheries

With the exception of the Taunton River and Cedar Swamp River bridges, all of the existing bridges are single-span bridges supported on stone abutments. Most of these bridges will be replaced by installing new abutments behind (landward) of the existing abutments to widen the bridge opening and provide an upland shelf for wildlife passage. Some replaced bridges will use new abutments at existing abutment locations. In-water work is restricted to removing the existing abutments and adding riprap, if necessary to stabilize the new shoreline. Erosion and sediment controls will be used to protect water quality. The Taunton River and Cedar Swamp River Bridges are multi-span bridges supported by steel pilings or piers in the river. Replacing these bridges will require that the new abutments be replaced by installing new abutments behind (landward) of the existing abutments to widen the bridge opening and provide an upland shelf for wildlife passage. New piers or pilings will be installed to support the new bridge structure, and the existing pilings will be removed. At the current conceptual design stage, it has not

[73] Pelletier SK, Carlson L, Nein D and Roy RD. 2006. Railroad crossing structures for spotted turtles: Massachusetts Bay Transportation Authority– Greenbush rail line wildlife crossing demonstration project. IN: Proceedings of the 2005 International Conference on Ecology and Transportation, Eds. Irwin CL, Garrett P, McDermott KP. Center for Transportation and the Environment, North Carolina State University, Raleigh, NC: pp. 414-425.

been determined if new pilings would be driven (from cranes located on shore or on barges) or if coffer dams would be required to install caissons. In-water work would be required for these bridges, as well as the in-water work needed to remove the existing abutments and add riprap, if necessary to stabilize the new shoreline. Erosion and sediment controls, including in-water sediment booms, will be used to protect water quality.

With the exception of the Taunton River, the applicant will generally be expected to observe the TOY restrictions recommended by the DMF for in water work as shown in Table 4.14-33. In general, these TOY restrictions would preclude in-water work from March 15 to June 30. Work outside of the waterway (on the bridge superstructure or on the new abutments) would not be subject to TOY restrictions. No TOY restrictions would be applicable to the Rattlesnake Brook bridge, which crosses over Route 24 (Rattlesnake Brook is below Route 24) or to Queset Brook, where bridge work would replace the superstructure only. DMF's suggested TOY restrictions for the Taunton River would allow only a 2-month, winter, work period for reconstruction of each of the four Taunton River bridges. This short construction period does not allow sufficient time to complete the installation of bridge supports. The applicant will coordinate with DMF to identify TOY restrictions and/or construction methods for the Taunton River that is adequate to protect fish spawning while allowing bridge construction to be completed.

Table 4.14-33 Massachusetts Division of Marine Fisheries-Recommended Time-of-Year Restrictions on In-Water Work

Waterway	Proposed Construction	Diadromous Fish Species	Time of Year Restriction
Assonet River	Reconstruct bridge – replace abutments to provide wider opening for fish and wildlife	Alewife, American eel, blueback herring, rainbow smelt, white perch	Jan. 15 to Nov. 15
Cedar Swamp River	Reconstruct two bridges – replace abutments to provide wider opening for fish and wildlife	American eel	March 15 to June 30
Cotley River	Reconstruct bridge – replace abutments to provide wider opening for fish and wildlife	American eel	March 15 to June 30
Fall Brook	Reconstruct bridge – replace abutments to provide wider opening for fish and wildlife	Alewife, American eel, blueback herring, white perch	March 15 to June 30, Sept. 1 to Nov. 15
Terry Brook Pond	Replace culvert to maintain hydrology and improve fish passage	American eel	March 15 to June 30
Black Brook	Construct new bridge (where old culvert washed out); replace 2 culverts. Design to improve fish passage.	American eel	March 15 to June 30
Mill River	Reconstruct bridge – replace abutments to provide wider opening for fish and wildlife	Alewife, American eel, blueback herring	Feb. 15 to June 30, Sept 1 to Nov. 15
Pine Swamp Brook	Reconstruct bridge – replace abutments to provide wider opening for fish and wildlife	American eel	March 15 to June 30
Rattlesnake Brook	Replace bridge over Route 24, no work in or adjacent to water	Alewife, American eel, blueback herring, rainbow smelt	None required – no work in water.

Waterway	Proposed Construction	Diadromous Fish Species	Time of Year Restriction
Queset Brook	Reconstruct bridge – retain existing historic abutments	American eel	None required – no work in water
Taunton River	Reconstruct four bridges – replace abutments to provide wider opening for fish and wildlife, reduce number of piers in the waterway.	Alewife, American eel, American shad, Atlantic sturgeon, blueback herring, rainbow smelt, white perch	Jan. 15 to Nov. 15
Whitman Brook	Reconstruct bridge – replace abutments to provide wider opening for fish and wildlife	American eel	March 15 to June 30

Breeding Bird Diversity

The National Migratory Bird Treaty is cited in the Secretary's Certificate as the trigger for mitigation measures to protect nesting birds. The Migratory Bird Treaty Act of 1918 (16 U.S.C. 703-712, as amended) states that, unless permitted by regulations, it is illegal to "pursue, hunt, take, kill, attempt to take, capture or kill, possess, offer for sale, sell, offer for purchase, purchase, deliver for shipment, ship, cause to be shipped, deliver for transportation, transport, cause to be transported, carry, or cause to be carried by any means whatever, receive for shipment, transportation or carriage, or export, at any time or in any manner, any migratory bird, included in the terms of this Convention … or any part, nest, or egg of such bird." As the U.S. Fish and Wildlife Service (USFWS) states, "we regulate most aspects of the taking, possession, transportation, sale, purchase, barter, exportation, and importation of migratory birds."

The USFWS does not, through the Migratory Bird Treaty Act, explicitly prohibit or regulate the incidental take of birds, bird nests, or bird eggs caused by land clearing. However, in response to the Secretary's Certificate, the applicant will not undertake vegetation removal in critical areas (Pine Swamp, Hockomock Swamp, Assonet Swamp, Acushnet Swamp) during the nesting season for migratory birds (May 1 through July 15).

Vernal Pools

Impacts to vernal pools and to their associated habitat created by the South Coast Rail project include direct fill of some vernal pools and decreases in vernal pool habitat, buffer habitat, and surrounding upland habitat. This section summarizes the potential avoidance, minimization, and mitigation measures to offset the impacts to vernal pools. During final design, additional field data will be collected to determine whether Potential Vernal Pools actually support breeding pool species, better define the limits of actual breeding pools, and refine the potential to make existing pools larger or create new pools near those it be impacted.

Avoidance—One of the most practicable ways to avoid impacts, particularly at locations where direct fill to vernal pools is small, is by slope modification in the final design phase of the project. Slope modification could include redesign of grading to create steeper slopes, including retaining walls, or a combination of both.

One of the largest avoidance measures of the South Coast Rail project is the trestle portion of rail (approximately 8,500 feet long) over the majority of Hockomock Swamp. The trestle would avoid direct

and indirect impacts to 9 vernal pools in Easton. In addition, the trestle would avoid impeding wildlife, including small amphibians, moving between pools across the existing berm. The trestle will avoid fragmentation of two clusters of pools in Easton: a cluster of five pools (CVPs 1660 through 1664) at the northern edge of the Hockomock Swamp area, and an additional cluster of three pools (CVPs 1665 and 1710, NHESP 2) just to the north of the first cluster.

Minimization—Where avoidance is not possible, impacts would be minimized to the maximum extent practicable. Minimization efforts generally employ the same strategies as avoidance; final design for the project would include some of the same design elements to minimize impacts such as steeper slopes and retaining walls where practicable.

Wildlife Passage—One of the most effective ways to mitigate for habitat fragmentation caused by constructing new tracks and widening existing berms is to construct wildlife crossings and replace existing culverts to allow for the passage of small amphibians across the right-of-way. These wildlife crossings and culvert upgrades can help to reconnect pools that are likely to experience fragmentation from a larger cluster of pools, such as VP 13 in Easton (Figure 4.14-7c). Wildlife crossings and culvert upgrades can also serve to reestablish former connectivity between areas where existing culverts have failed or collapsed, such as between EA-1 and EA-2 in Easton (Figure 4.14-7c). Crossings would be placed in areas where habitat fragmentation is most likely to occur, at or near areas where clusters of vernal pools exist.

Protection—Potential mitigation measures also include purchasing land containing vernal pools or placing a conservation restriction on land containing vernal pools. These areas, as well as any associated vernal pool habitat, buffer habitat, and surrounding upland habitat, would be protected from further encroachment by these measures. This type of mitigation would likely be most effective if a cluster or highly active area of vernal pools were purchased or placed under protection. For example, a cluster of vernal pools in Easton is present on land owned by the Southeastern Regional Vocational Technical High School; this cluster includes pools CVPs 1660, 1664, and 1661. Land on the opposite side of the right-of-way is owned by the Town of Easton and includes CVPs 1663 and 1662. Another cluster of pools including PVP 7222, CVP 2152, PVP 7233, and VP 10 is present in North Easton on land under private ownership. The applicant will work with these adjacent landowners to protect vernal pools adjacent to the right-of-way at these locations through conservation restrictions or similar measures.

Protecting existing vernal pool areas can also come through discouraging public abuse of the area. Impacts to vernal pools along the right-of-way are currently occurring as a result of human use of the right-of-way, particularly on abandoned portions of track. Human traffic along trails around vernal pool areas can affect the use of pools by obligate vernal pool species. In particular, ATV users ride through vernal pool areas late in the season when the pools become shallower and begin to dry out. This can increase mortality both of the developing young amphibians in the pool and juveniles leaving the pool. Much of this ATV use occurs along the abandoned portion of track in Easton. The trestle will discourage ATV riders from using that portion of the berm, since the physical presence of the trestle will make riding along that section of the berm impossible. ATV use has also damaged vernal pools on the Southeastern Regional School and Town of Eason land south of Foundry Street. The applicant will work with these landowners to identify protection measures, potentially including fencing, to protect these pools.

Habitat Enhancement—Impacts to vernal pools and their associated habitats can also be mitigated by enhancing remaining habitats and creating new habitats. For pools that are filled completely, new pools

can be created, where feasible, in nearby areas. For example, VP 13 in Taunton lies in the right-of-way and would be completely filled. The two adjacent parcels on either side of the right-of-way consist of undeveloped land under the same private ownership. As with placing existing pools under protection, the applicant would work with adjacent landowners to identify and pursue constructing these replacement areas where appropriate.

Properly-constructed vernal pools will replicate the hydrology and functions of a filled pool in most cases,[74] and field techniques exist for simulating hydrological conditions when constructing pools, such as through the use of liners in more permeable soils.[75] The substrate of the vernal pool to be filled contains much of the organic matter that supports the food web associations of the pool. When creating a new vernal pool, the substrate of the existing pool can be taken from the pool before it is filled and transplanted to the new pool to aid in its establishment.

Expansion of existing vernal pools that would receive fill is one potential option for mitigating vernal pool impacts. Conceptually, vernal pool enlargement would expand the area of potential breeding habitat for vernal pool species including individual animals displaced by the fill. However, creating the expanded area would require either the disturbance (at least temporarily) of additional vernal pool habitat wetlands, or existing upland buffer. In addition, it would be necessary to ensure that vernal pools are constructed/expanded well-removed from developed areas where vernal pool species are more susceptible to predation by raccoons and domesticated animals. In general, it is expected that this option would be applied on a limited basis, and that the resulting constructed vernal pools would be closely monitored to ensure their ultimate success as viable habitats for vernal pool-dependent fauna.

Plantings around pools can help maintain healthy vernal pool ecosystems. New shrub and tree plantings in areas where pools would receive impact would help native vegetation reestablish itself. Once mature, areas of plantings would contribute additional leaf litter and other detrital inputs, and would help shade the pool and regulate its temperature. Plantings would be especially appropriate in areas where the existing surrounding vegetation contains invasive or other low-value species, such as purple loosestrife or common reed. These areas would benefit from plantings that would return the area to a more natural vernal pool habitat such as a red maple swamp, shrub swamp, or emergent marsh. As a possible example, VP 10 in Easton (Figure 4.14-7b) is a vernal pool that would receive direct fill, but that has both upland and wetland habitats adjacent to it and within 100 feet of its boundary. The wetland area surrounding VP 10 is a forested wetland associated with Whitman Brook to the south. Plantings at the edge of disturbance of this pool consistent with a forested wetland – for example, red maple would be potentially appropriate. Plantings would need to be consistent with vegetation management policies maintained by the railway operators. For example, trees should not be planted at the edge of a berm where, when mature, they would encroach upon the right-of-way. In the example of VP 10 above, as an alternative to red maple trees, areas at the edge of the right-of-way could be planted with native shrubs such as buttonbush (Cephalanthus occidentalis) to enhance the habitat of the area.

Fish and Wildlife Passage

This section describes the methodology for assigning mitigation and the recommended mitigation measures to enhance biodiversity by improving certain South Coast Rail bridges and culverts to facilitate wildlife and fish passage through the railroad bed.

Types of Wildlife and Fish Crossings—Wildlife and fish crossings vary according to the species addressed and the physical characteristics of the crossing locations. Wildlife, being more broadly mobile than fish, can use a wide range of crossing types. Depending on an animal's mobility, it may cross directly over the tracks unimpeded (but at risk for collision with trains), cross over tracks on overpasses, or cross under the tracks at bridge, culvert or trestle locations. Physical size or behavioral characteristics can affect animals' ability to use these crossings. Large mammals such as deer are unable to fit through small structures or those filled with water, and generally unwilling to enter structures that they cannot see through. Overpasses or large-opening underpasses are the best types of crossings for these animals. Small reptiles such as turtles may be blocked by rails (or become trapped between two rails) or unable to negotiate culverts with rapidly flowing water. Culverts that duplicate natural stream conditions, or tunnels that provide dry passage, are the best types of crossings for these animals. Between-tie open-top crossings at the ground surface may allow trapped reptiles to escape. Drift fences may prevent direct track crossing or guide turtles and other animals to crossing locations.

Fish are constrained to rivers, streams, and ponds, and therefore must use crossings that convey water through or under the railroad bed (e.g., culverts or bridges) at appropriate depths and flow rates. Culverts that mimic up- and downstream conditions of slope, substrate, and water volume provide the best crossings through the railroad bed for fish. Bridges do not typically affect fish passage.

Numerous guidance documents about structures that facilitate fish and wildlife passage across linear facilities (whether roads or railroads) have been prepared by or for federal and state fish and wildlife, land management, and transportation agencies. The *Massachusetts River and Stream Crossing Standards,* [76] developed by a partnership of agencies and other stakeholders, are most applicable to the bridges and culverts along the Stoughton Alternative. The *Wildlife Crossing Structure Handbook* [77] (the Handbook) provides guidance on amphibian tunnels and drift fences that is useful for between-tie structures. Guidelines for bridges and culverts, tunnels, and drift fences from these sources are summarized in the next sections. Wildlife overpasses have generally been used more frequently in the west, and are not appropriate for the South Coast Rail project because large mammals (moose, elk, bighorn sheep) are not present and wildlife that are present can use culverts or bridges, or cross tracks directly with little danger from the infrequent South Coast Rail trains.

The University of Massachusetts- Amherst (College of Natural Sciences), The Nature Conservancy, Massachusetts Division of Ecological Restoration- Riverways Program, American Rivers, and others. August 2004; revised March 1, 2006; revised March 1, 2011; corrected January 31, 2012.

[77] US Federal Highway Administration. 2011. *Wildlife Crossing Structure Handbook: Design and Evaluation in North America*. Publication No. FHWA-CFL/TD-11-003. Lakewood, CO: US Department of Transportation, Federal Highway Administration, Central Federal Lands Highway Division.

River and Stream Crossing Standards for Bridges and Culverts—The Massachusetts River and Stream Crossing Standards[78] (the Standards) are intended for fish-bearing streams but can be applied to other areas where wildlife species that use riparian habitat are present. The Standards seek to achieve:

- fish and other aquatic organism passage;
- river and stream continuity; and
- wildlife passage.

The Standards state that full "aquatic organism passage" is achieved when a crossing allows unrestricted movement of all aquatic organisms indigenous to the water body. "Aquatic organism" means fish and the aquatic life stages of other vertebrates (amphibians), and aquatic invertebrates including small benthic fauna that typically reside within the stream substrate. "Unrestricted movement" means that all individuals and all life stages are able to move through the structure as freely as they can through the natural stream channel and without delays or obstructions caused by the crossing structure. Crossing structures that achieve full aquatic organism passage are expected to maintain natural river hydrology and transport sediment and woody debris.

The Standards acknowledge that it is impractical to use a species-based approach for designing stream crossings because the ideal design for one species may differ from the ideal for another species occupying the same habitat. It is more practical to recreate natural stream conditions and allow resident species to use the crossing as if it were an unaltered segment of the stream. The Standards therefore use a "Stream Simulation" [79] approach for crossing design. According to the Standards,

> "Stream Simulation is an ecosystem-based approach that focuses on maintaining the variety and quality of habitats, the connectivity of river and stream ecosystems, and the essential ecological processes that shape and maintain these ecosystems over time. Stream Simulation is a design approach that avoids flow constriction during normal conditions and creates a stream channel that maintains the diversity and complexity of the streambed through the crossing. Crossing structures that avoid channel constriction and maintain appropriate channel conditions (channel dimensions, banks, bed, and bed forms) within the structure should be able to accommodate most of the normal movements of aquatic organisms, and preserve (or restore) many ecosystem processes that maintain habitats and aquatic animal populations. The goal is to create crossings that are essentially "invisible" to aquatic organisms by making them no more of an obstacle to movement than the natural channel."

General or Optimum standards are provided to balance the cost and logistics of crossing design with the degree of river/stream continuity warranted in areas of different environmental significance. General standards are applicable for crossings on rivers or streams (including intermittent streams) serving as habitat for fish and semi-aquatic wildlife that typically live within stream channels (salamanders, turtles). These crossings should at least pass most fish species, maintain river/stream continuity, and facilitate passage for some wildlife. The Optimum standards are applicable for stream crossings in areas

[78] River and Stream Crossing Partnership. 2011. Massachusetts River and Stream Crossing Standards. The University of Massachusetts- Amherst (College of Natural Sciences), The Nature Conservancy, Massachusetts Division of Ecological Restoration- Riverways Program, American Rivers, and others. August 2004; revised March 1, 2006; revised March 1, 2011; corrected January 31, 2012.

of particular statewide or regional significance for their contribution to landscape level connectedness. In addition to the aquatic species benefits provided by the General standards, the Optimum standards better accommodate terrestrial wildlife.

The General standards are:

- Spans (bridges, 3-sided box culverts, open-bottom culverts or arches) that preserve the natural stream channel are strongly preferred over structures with a closed bottom.
- If the crossing is a box culvert (with a closed bottom), then it should be embedded:
  - A minimum of 2 feet below the substrate for all culverts, and
  - A minimum of 2 feet below the substrate and at least 25 percent of the total area for round pipe culverts.
- When embedment material includes elements greater than 15 inches in diameter, embedment depths should be at least twice the D84 (particle width larger than 84 percent of particles) of the embedment material.
- The structure should span the channel a minimum of 1.2 times the bankfull width in order to avoid channel constriction during normal bankfull flows. The bankfull width should be measured at straight sections of the channel outside the influence of existing structures and unusual channel characteristics.
- The substrate within the structure should match the characteristics of the substrate in the natural stream channel (mobility, slope, stability, confinement) at the time of construction and over time as the structure has had the opportunity to pass significant flood events.
- The structure floor should be designed with appropriate bed forms and streambed characteristics so that water depths and velocities are comparable to those found in the natural channel at a variety of flows.
- The structure should have an openness ratio of greater than 0.82. The openness ratio is the cross-sectional area of a structure opening divided by its length. For structures with multiple cells or barrels, openness is calculated separately for each cell or barrel, at least one of which should meet the appropriate openness standard. The embedded portion of a box culvert is not included in the calculation of cross-sectional area for determining openness.
- Banks should be present on each side of the stream matching the horizontal profile of the existing stream and banks. All constructed banks should have a height to width ratio of no greater than 1:1.5 (vertical: horizontal) unless the stream is naturally incised. The banks should be designed and constructed so as not to hinder riverine wildlife use of the streambed and banks for passage.

The Optimum standards' application to areas of particular statewide or regional significance recognizes their contribution to landscape level connectedness. The Optimum standards define these significant areas as including rivers or streams and associated riparian areas that serve as corridors or connecting habitat-linking areas of significant habitat (greater than 250 acres) in three or more towns. Although not

directly comparable to the IEI values represented by the CAPS analysis, the Optimum standards' concept of significant areas as large tracts of minimally altered landscapes is similar. The Optimum standards have three modifications of the General standards:

- Bridges are specified, instead of open spans. (The "embedded culvert" standard is omitted from the Optimum standards, as it is not needed for bridges.)
- A minimum height of 8 feet (2.4 meters) and openness ratio of 2.46 should be maintained if conditions are present that significantly inhibit wildlife passage (high traffic volumes, steep embankments, fencing, Jersey barriers or other physical obstructions). If conditions that significantly inhibit wildlife passage are not present, a minimum height of 6 feet (1.8 meters) and openness ratio of 1.64 should be maintained.
- Banks should be present on each side of the stream matching the horizontal profile of the existing stream. The portion of the structure over the banks should have sufficient headroom to provide dry passage for semi-aquatic and terrestrial wildlife.

Both the General and Optimum standards are applicable for constructing new and replacing existing culverts and bridges, depending upon the landscape as described above. Culvert replacement offers a better opportunity to integrate the Standards. The Standards' recommendations for replacing existing culverts are summarized in the following paragraphs.

Replacement culverts should meet the design guidelines for either General standards or Optimum standards unless:

- Doing so would result in significant stream instability that cannot otherwise be mitigated;
- Meeting the Standards would create a flooding hazard that can't otherwise be mitigated; or
- Site constraints make it impossible to meet the Standards.

If it is not possible to meet all of the applicable Standards, replacement crossings should be designed to avoid or mitigate the following problems:

- Inlet drops – occur where water level drops suddenly at an inlet, causing changes in water speed and turbulence. In addition to the higher velocities and turbulence, these jumps can be physical barriers to fish and other aquatic animals when they are moving upstream and are unable to swim out of the culvert.
- Outlet drops – occur when water drops off or cascades down from a structure outlet, usually into a receiving pool. This may be due to the original culvert placement, erosion of material at the area immediately downstream of the culvert, or downstream channel adjustments that may have occurred subsequent to the culvert installation. Outlet drops are barriers to fish and other aquatic animals that can't jump to get up into the culvert.
- Flow contraction that produces significant turbulence – occur when a culvert or other crossing structure is significantly smaller than the stream width the converging flow creates a condition called "flow contraction." The increased velocities and turbulence associated

with flow contraction can block fish and wildlife passage and scour bed material out of a crossing structure. Flow contraction also creates inlet drops.

- Tailwater armoring – consist of concrete aprons, plastic aprons, riprap or other structures added to culvert outlets to facilitate flow and prevent erosion.

- Tailwater scour pools – are created downstream from high flows exiting the culvert. The pool is wider than the stream channel and banks are typically eroded. Some plunge pools may have been specifically designed to dissipate flow energy at the culvert outlet and control downstream erosion.

- Physical barriers to fish and wildlife passage – these barriers include any feature that physically blocks fish or wildlife movement through a crossing structure as well as features that would cause a crossing structure to become blocked. Beaver dams, debris jams, fences, sediment filling a culvert, weirs, baffles, aprons, and gabions are examples of structures that might be or cause physical barriers. Weirs are short dams or fences in the stream that constrict water flow or fish movements. Baffles are structures within culverts that direct, constrict, or slow down water flow. Gabions are rectangular wire mesh baskets filled with rock that are used as retaining walls and erosion control structures. Steeply sloping channels within a structure resulting in shallow flows and/or high velocity flows can also inhibit movement of fish and other aquatic organisms.

Other design guidelines for replacing culverts are:

- Avoid pipes that are too smooth (as defined by the Standards) so as to facilitate upstream migration of aquatic organisms.

- As indicated by long profiles, scour analyses, and geomorphological assessments, design the structure and include appropriate grade controls to ensure that the replacement will not destabilize the river/stream.

- To the extent practicable conduct stream restoration upstream and/or downstream of the structure as needed to restore river/stream continuity and eliminate barriers to aquatic organism movement.

Guidelines for Other Crossing Structures—Tunnels (similar to small culverts but without a hydrologic function) and between-tie crossings provide crossing opportunities for small mammals, reptiles, and amphibians in upland locations where culverts or bridges are not located. Between-tie crossings also allow animals that become entrapped between rails to enter the structure and escape underneath the rails.

Reptiles and amphibians have special requirements for wildlife crossing design since they are unable to orient their movements to locate tunnel or between-tie crossing entrances. Drift fences play a critical function in intercepting amphibians and reptiles, directing them to the crossing structures. The Handbook provides guidance on tunnel and drift fence design for structures underneath roadways; the guidelines, as adapted for railroad beds and applied to between-tie crossings, are:

- Large tunnels provide good airflow and natural light conditions for reptiles and amphibians to pass through in a natural-appearing environment.

- Tunnels and between-tie crossings should be sited in known routes of seasonal migration, dispersal or other movement events for the target species. Reptiles and amphibians are not likely to use these structures unless they are located in migratory routes, within preferred habitat, or in general area where dispersal events may occur.

- Continuous habitat or vegetative cover leading to the structure should be provided. The area may need to be re-vegetated after construction to restore habitat conditions and provide important cover during migrations and other movement events.

- The floors of the structures should be covered with native soil (sandy loam if possible) to provide a more natural substrate for travel, placed in continuity with the ground surface in the area. In migration route areas, the distance between tunnels or between-tie crossings should be 150 feet (45 meters) or less, but a 200 foot (60 meter) distance could be used if drift fences are funnel-shaped to guide amphibians to the structure, as described in the following section. The structures should be level and designed to conform to local topography, but drainage should be directed away from the structures to prevent flooding within.

- Tunnels may be rectangular or circular in cross-section; between-tie crossings are rectangular in cross-section. Prefabricated rectangular and square/box designs are preferred because vertical walls facilitate the movement of amphibians and reptiles through the structure. Pipes are not desirable because the animals may attempt to climb the slope of the wall instead of proceed through the structure. The cross-section of an amphibian and reptile tunnel should increase with tunnel length, as recommended in Table 4.14-34. Surface materials may be prefabricated concrete or polymer. Metal is not desirable because of its high thermal conductivity and resulting coldness, especially during spring migratory periods.

Table 4.14-34 Tunnel Dimension Recommendations

	Tunnel Length (feet)				
Type	**<65**	**65-100**	**100-130**	**130-165**	**165-200**
Rectangular (width X height)	3.2 X 2.5	5.0 X 3.2	5.75 X 4.0	6.5 X 5.0	7.5 X 5.75
Circular (diameter)	3.2	4.5	5.25	6.5	8.0

Source: US Federal Highway Administration. 2011. Wildlife Crossing Structure Handbook: Design and Evaluation in North America.

- Between-tie crossings are open-top to allow animals trapped between rails to escape underneath the rails in a 7- to 8 inch deep trough. These structures should be rectangular and include a natural material bottom. The dimensions of between-tie crossings are constrained by the distance between the ties and limited to the length of the ties.

- Funneling walls of limited length should be constructed to direct animals to between-tie crossings. Lengthy drift fences (as described below) would not be associated with between-tie crossings; there would be a risk that animals could get trapped between the drift fence and the rails. For the same reason, between-tie crossings would not be installed where drift fences are associated with tunnels or culverts.

Recent experience on the MBTA's Greenbush Line provides insight on between-tie crossing value for turtles. In association with the Greenbush Line Commuter Railroad Restoration Project, the MBTA initiated a demonstration project in spring of 2003 to determine the effectiveness of a proposed railroad crossing structure in an urbanized landscape.[80] Three identical, open-air prototypes were positioned in the right-of-way of a former railroad bed between adjacent wetlands known to support turtles. Each structure was linked with temporary funneling barriers along the track edges.

To evaluate the effectiveness of the structures, remote photographic stations were established at each crossing, and radio telemetry was used to track turtle movements. Study results demonstrated that turtle crossing patterns and frequency through the right-of-way during the monitoring period were similar to those prior to when the barrier was constructed. The crossings were also used by other wildlife species, including reptiles (eastern garter snake [*Thamnophis sirtalis*]) , amphibians (green frog [*Rana clamitans*]), birds (wood duck [*Aix sponsa*], mallard [*Anas platyrhynchos*]), and mammals (coyote [*Canis latrans*], gray fox [*Urocyon cinereoargenteus*] , muskrat [*Ondatra zibethicus*], longtailed weasel [*Mustela frenata*], eastern cottontail [*Sylvilagus floridanus*], raccoon, striped skunk [*Mephitis mephitis*], opossum [*Didelphis virginiana*], eastern grey squirrel [*Sciurus carolinensis*], eastern chipmunk [*Tamias striatus*], mouse species). The demonstration project concluded that the location and design of the crossing structures provided an effective means of maintaining habitat connectivity for a variety of wildlife species, including turtles (spotted, snapping, and painted turtles). As part of the Conservation and Management Plan developed for the Greenbush Line, 45 wildlife crossing structures, with funneling walls, were installed at key locations along the right-of-way. The type of crossing structure used on the Greenbush Line is largely open to ambient conditions and, therefore, most effective in mimicking the natural conditions typically encountered by turtles (e.g., substrate, moisture, temperature, light).

Guidelines for Drift Fences—Drift fences are used to prevent small animals (reptiles and amphibians in particular) from entering the track area and to direct them to crossing locations. The following design guidelines offered by the Handbook have been adapted to the specific characteristics of a railroad such as the South Coast Rail.

- Drift fences should be installed at the base of the railroad bed slope, tied into the culvert or tunnel entrance and avoiding any surface irregularities that might impede or distract movement towards the entrance.
- Wing walls should angle out from each end of the culvert or tunnel at approximately 45 degrees to orient animals that move away from the structure towards natural environment.
- Drift fences should be 1.25 feet (0.4 meter) high and must be entirely opaque, of smooth fabric (rigid plastic, polythene, canvas) and with vertical walls. Fences made of translucent material or wire mesh are not recommended because some amphibians try to climb over them instead of moving towards the structure. Bowed or curved walls can obstruct the travel of some amphibians moving towards the structure. Stakes should be placed on the railroad side of the drift fence and not the opposite, which would obstruct amphibian movement.

---

[80] Pelletier SK, Carlson L, Nein D and Roy RD. 2006. Railroad crossing structures for spotted turtles: Massachusetts Bay Transportation Authority– Greenbush rail line wildlife crossing demonstration project. IN: Proceedings of the 2005 International Conference on Ecology and Transportation, Eds. Irwin CL, Garrett P, McDermott KP. Center for Transportation and the Environment, North Carolina State University, Raleigh, NC: pp. 414-425.

- To prevent breaching by climbing amphibians and reptiles, fence designs that are concave or create an overhang or lip have been used successfully. Fencing should be clear of obstructions and vegetation. Overhanging vegetation close to the fence has resulted in animals climbing over the fence onto the railroad.

The bottom section of the drift fence should be secured to ground, not leaving any gaps.

Methodology for Assigning Mitigation—Each of the bridge and culvert locations was reviewed to determine the ecological value of the passage and the suitability of applying the Standards and other mitigation measures, taking into consideration the engineering constraints described previously for the proposed bridge and culvert replacements. The proposed mitigation measures for the bridges considered in this evaluation were assigned based on the structure's location over water or over land. As described previously, bridges over water would be replaced to meet the Standards unless site-specific constraints prevent, while bridges over land would be replaced in kind.

The broad range of culvert locations warranted a more detailed analysis. The criteria used to identify appropriate culvert sites warranting mitigation measures were:

- Surrounding land development density should be rural or, in rare instances, suburban in the general vicinity of the structure.
- Surrounding land use should be open space, with other uses permissible if other site characteristics result in unique ecological value at the structure location.
- CAPS results should indicate an IEI value of 50 percent or higher for forests or freshwater wetland and aquatic landscapes on both sides of the railroad at the structure location, (culverts found between areas of high ecologic integrity (see Appendix 4.14-B); and
- Rivers, streams, ponds, wetlands, and uplands should have suitable habitat for fish and wildlife.

Based on these criteria, a decision tree (Figure 4.14-42) was developed to assist in determining mitigation recommendations for each culvert. As previously described, mitigation measures for the culverts would be:

- replace to meet the Standards;
- replace in kind;
- daylight; or
- subject to hydraulic analysis to determine if the structure is providing hydrologic control, (i.e., maintaining ambient hydrology in a functioning wetland, the alteration of which could cause unintended adverse consequences to the wetland), resulting in a range of recommended outcomes.

Criteria for additional tunnel and between-tie crossings (discussed in more detail below) include:

- Known ranges for rare species (e.g., Blanding's turtle, blue-spotted salamander, Eastern box turtle)

- Migration routes for rare species
- Presence or absence of culverts or bridges in the vicinity of migration routes
- Presence of vernal pools

Proposed Mitigation Measures

Bridges—The Stoughton Alternative includes only one new bridge (replacing a washed-out culvert) and one new trestle (above several existing culverts); there will be no new river or stream crossings. The new bridge, trestle, and all replacement bridges will use existing or replacement abutments at or near current abutment locations. The bridges over rivers, perennial streams, and abandoned farm roads will be replaced as previously described (see Table 4.14-18). Most of the bridges over rivers and streams will be designed to meet Standards, in particular including shelves on the waterfront banks to allow for wildlife passage (Figure 4.14-42). This will be accomplished in part by constructing new abutments behind existing abutments, and then partially or fully removing the existing abutments. In some cases, the existing abutments will not be replaced, or will be replaced at the same location, to preserve historic structures or meet spatial constraints. In these cases, the bridge would not incorporate wildlife crossing features. Bridges with several spans will be replaced with single or dual-span structures, reducing or eliminating impediments to fish passage in the river or stream.

Constructing the bridges over rivers or streams will take into consideration the DMF's recommendations for time-of-year restrictions for diadromous fish to the extent practical or use construction techniques (e.g., containment structures) that do not affect fish passage or use of spawning riffles (see Section 4.14.3.2).

A few of the bridges considered in this biodiversity assessment are in upland locations, and do not span rivers or streams. As previously noted, some of these structures accommodate flood flow, particularly near the Taunton River in Fall River, where Land Subject to Coastal Storm Flowage is mapped. These upland bridges may provide open passage to non-aquatic species, principally mammals and reptiles, but are generally in locations with low biodiversity. For these reasons, in-kind replacement is recommended.

An 8,500-foot long trestle will be constructed over a portion of the Hockomock Swamp, above the abandoned railroad bed. The trestle would be elevated three to four feet above the existing railroad berm to provide for large animal passage underneath. As noted below, existing culverts within this segment of the railroad will be "daylighted" (top section removed) to enhance their ecological value.

On the Whittenton Branch alignment piers or pilings supporting the existing Mill River Bridge would be replaced by a single pier at the center of a two-span structure, minimizing impacts to stream hydrology and fish habitat. Existing piles would be removed and one new cast-in-place concrete pier would be constructed in the center of the span. New cast-in-place concrete abutments would be constructed behind the existing abutments, which would then be partially removed to an elevation equal to the river's average seasonal high water elevation to improve wildlife passage

Culverts—Mitigation recommendations for each culvert along the Stoughton Alternative are summarized in Table 4.14-35 and described below.

Table 4.14-35 Recommendations for Culverts

	Meet Standards	Hydraulic Analysis	Daylight	Replace in Kind	Eliminate
Stoughton Line	20	3	6	20	1
New Bedford Main	10	6	0	12	0
Fall River Secondary	3	5	0	18	1
Total	33	14	6	50	2

As shown in the decision tree (Figure 4.14-42), of the 105 culverts 77 connect areas of high biodiversity while 28 do not. The functional analysis of the 77 culverts determined that 53 of these culverts did provide a water-body related service while 24 do not. For the 53 culverts that provide a water-body related function connecting areas of high biodiversity, each was evaluated to determine if the culvert provides hydrologic control of an upstream wetland. Thirty-three of these culverts were determined to not provide hydrologic control; these culverts would be replaced to the Standards to the extent practicable (that is, taking into consideration the engineering constraints described above). The 33 culverts recommended for replacement to the Standards would meet the General standards, in particular the 1.2 times bankfull width, open bottom, and 0.82 openness ratio requirements. None of the culverts would be replaced with bridges to meet Optimum standards (e.g., spans) because the expense of that level of upgrade is not warranted. Table 4.14-36 lists the 33 culverts that would be replaced to meet the General Standards, facilitating fish and wildlife passage through culverts that convey perennial streams and wildlife passage (including aquatic species) through all other culverts.

A typical culvert cross-section meeting the Standards is depicted in Figure 4.14-43. The actual specifications for each structure will be determined on a location-specific basis during preliminary design, meeting the General standards and taking into consideration the engineering constraints as appropriate. As an example, a 40-foot long culvert would have a 32 square foot opening, likely 8 feet wide and 4 feet high.

A preliminary engineering review of the 33 culverts recommended to meet the Standards, based on these example specifications, determined that 20 of those culverts did not have sufficient cover to accommodate a 4-foot high structure. Raising the track bed to meet this cover requirement is not practicable due to the elevation change constraints of a high-speed commuter railroad. Actual specifications for each culvert will be determined during final design; the 0.82 openness ratio will be incorporated if feasible. Smaller openness ratios may be necessary to accommodate the cover requirements. The river and stream crossing standards for bridges and culverts, as described above, include provisions if it is not possible to meet all of the applicable Standards. Replacement of any of these structures will take into consideration other specifications of the General standards to the extent practical.

Table 4.14-36 Culverts Recommended to Meet General Massachusetts River and Stream Crossing Standards[81]

Culvert	Figure Number	Existing Structure Description	Hydrologic Function
CV-ST 6.45	4.14-11b	4'X2.5' stone box culvert, 75' long	Intermittent stream conveyance
CV-ST 6.69	4.14-11b	3'X3' stone box culvert, 70' long	Wetland equalizer

CV-FR 5.79	4.14-13b	3'X5' stone box culvert, unknown length	Wetland equalizer

1 Culvert not associated with Whittenton Alternative

[81] River and Stream Crossing Partnership. 2011. Massachusetts River and Stream Crossing Standards. The University of Massachusetts- Amherst (College of Natural Sciences), The Nature Conservancy, Massachusetts Division of Ecological Restoration- Riverways Program, American Rivers, and others. August 2004; revised March 1, 2006; revised March 1, 2011; corrected January 31, 2012

Of the remaining 20 culverts that have a water-body related function and appear to provide hydrologic control of a wetland, hydraulic analysis is recommended for 14. If the culvert is not providing hydrologic control, it would be replaced to the Standards as described for the 33 culverts above. If the culvert is providing hydrologic control, it should either not be replaced (if replacement is not necessary for engineering reasons) or be replaced without altering the local hydrology (if replacement is necessary for engineering reasons). This could be accomplished by installing a weir on the upstream side of the culvert, albeit fish passage (if any) could be compromised by such an approach.

The last six culverts within this group lie within the segment of the Stoughton Line that would be traversed by the new trestle; these culverts would be daylighted. These particular structures will be beneath the trestle within the abandoned railroad bed. These culverts would function more effectively for reptile and amphibian passage across the railroad bed if they have open tops. Removing the layer of railroad ballast above the existing culverts and the top member of the stone or stone/rail box culverts is recommended for these structures.

Two of the 28 culverts that do not connect areas of high biodiversity could be eliminated because they do not appear to have any hydrologic or ecologic value. These two culverts (an un-numbered culvert in Easton immediately south of Foundry Street [Figure 4.14-11c] and CV-FR 8.97 in Fall River [Figure 4.14-13b]) are currently entirely plugged.

The remaining 26 culverts in that do not connect areas of high biodiversity, combined with the 24 culverts that do not have a water-body related function, result in 50 culverts that may be replaced in kind according to engineering requirements of the South Coast Rail project.

Tunnels and Between-Tie Crossings—Tunnels and between-tie crossings would be sited within known habitat for turtles and salamanders at upland locations where there are no existing culverts or bridges, such as within the Hockomock Swamp, Pine Swamp, Assonet Cedar Swamp, and Acushnet Cedar Swamp. An adequate number and density of crossings would be placed at vernal pool complexes and near grade crossings to allow turtles that wander onto the railroad or get stuck between the tracks to escape. Potential locations for these structures are depicted in Figures 4.14-11a through 4.14-13c and listed in Table 4.14-37. However, the actual type of wildlife crossing would be determined during final design, based on topography. The between-tie crossings would be designed in accordance with the Handbook recommendations described above; a typical structure is depicted in Figure 4.14-44.

Mitigation recommendations for each culvert along the Whittenton Alternative are summarized in Table 4.14-38. For culverts that appear to have some hydraulic control over wetland areas (i.e., are wetland equalizers), mitigation would begin with a hydraulic analysis to determine whether culverts should be replaced in kind (with no change to hydraulic function) or replaced according to the Massachusetts River and Stream Crossing Standards to the extent practicable (which could alter the hydrology of some areas). Daylighting of culverts to facilitate animal passage could be performed on culverts that connect areas of wildlife habitat.

Tunnels and between-tie crossings are likely to have little effect on areas of the Whittenton Branch north of Warren Street since the eastern side of the tracks contains little undeveloped land. South of Warren Street, in the vicinity of Wetlands TWB 05 through TWB 01, both the western and eastern sides of the tracks have large areas of undeveloped land that could benefit from daylighted culverts or other crossing measures.

Table 4.14-37 Proposed Tunnel and Between-Tie Crossing Locations

Crossing Type	Location	Connects	Figure Number
Type To Be Determined	Stoughton Line: South of North Easton Station site, Easton	CVPs and PVPs	4.14-11b
(2) Between-Tie	Stoughton Line: Easton Country Club Golf Course, Easton	Blanding's turtle habitat	4.14-11c
Tunnel	Stoughton Line: North of Foundry Street, Easton	Blanding's turtle habitat	4.14-11c
(3) Type To Be Determined	Stoughton Line: North of Bridge Street, Raynham	High-integrity forest on east and west sides	4.14-11d
Tunnel[1]	Stoughton Line: Pine Swamp, Raynham	High-integrity swamp on east and west sides	4.14-11d
Between-Tie	Stoughton Line: North of Raynham/ Taunton municipal boundary, Raynham	PVPs	4.14-11e
Between-Tie	Stoughton Line: South of Raynham/ Taunton municipal boundary, Taunton	PVPs	4.14-11e
Tunnel	New Bedford Main Line: South of Taunton Depot Station site, Taunton	PVPs	4.14-11e
Between-Tie	New Bedford Main Line: South of Malbone Street, Lakeville	High-integrity forest on east side and swamp on west side	4.14-12a
Type To Be Determined	New Bedford Main Line: North of Lakeville/ Freetown municipal boundary	High ecological integrity forest on east and west sides	4.14-12b
Between-Tie	New Bedford Main Line: North of Braley Road	Eastern box turtle habitat; high ecological integrity forest on west side	4.14-12c
Between-Tie	Fall River Secondary: South of Elm Street	High ecological integrity forest and PVP on east side; pond on west side	4.14-13a

1 Measure not associated with Whittenton Alternative

Table 4.14-38 Recommendations for Culverts–Whittenton Alternative

	Meet Standards	Hydraulic Analysis	Daylight	Replace in Kind	Eliminate
Stoughton Line – Canton, Stoughton and Easton	16	2	6	18	1
Whittenton Alternative – Raynham and Taunton	4	7	0	0	0
New Bedford Main	10	6	0	12	0
Fall River Secondary	3	5	0	18	1
Total	33	17	6	48	2

While there are no complexes of vernal pools along the Whittenton Branch, animals may still cross over the right-of-way moving to and from individual pools, wetlands, or upland areas.

In addition to replacement of the culverts in this section to facilitate wildlife passage, up to two additional culverts have been proposed in the DEIS/DEIR in this section of the Whittenton Branch to maintain wildlife habitat that exists on both sides of the tracks.

This section of the right-of-way is also in eastern box turtle habitat and would facilitate the crossing of turtles under the tracks, since constructing the tracks would create a barrier to movement across the currently inactive right-of-way.

Much of the area on both sides of the tracks in this section has been identified as wetlands; however, there is a stretch of approximately 200 feet between Wetlands TWB 04 and TWB 02 on the eastern side of the tracks, and Wetlands TWB-03.1 and TWB 01 on the western side of the tracks that are uplands. This area would be the preferred location for additional wildlife passage or passages under the right-of-way.

Design of culverts and other crossing measures would be as described in the Biodiversity Technical Report for the Stoughton Alternative. Treatments of culverts and bridges along the remainder of the Whittenton Alternative (from Canton to Raynham Junction and south of Weir Junction) would be the same as for the Stoughton Alternative.

Timing and Methods of Construction—Timing of construction may affect the extent of impacts to fish and wildlife species. Disturbance of habitat during the breeding season is likely to have greater short-term or individual effects on reproductive success, though short-term effects are not likely to have long-term repercussions unless the species population is already unstable. To avoid potential short-term effects to breeding wildlife, all efforts will be taken to avoid construction during the breeding season (April through June) in Hockomock and Pine Swamps. In all cases construction would be limited to normal daylight hours.

Construction impacts to aquatic resources will be mitigated by the appropriate use of erosion and sedimentation controls to minimize and eliminate sedimentation of wetlands and waterways. Erosion and sedimentation controls would be installed before construction begins, properly maintained, and removed after disturbed areas have stabilized.

4.15 THREATENED AND ENDANGERED SPECIES

4.15.1 **Introduction**

This chapter describes existing conditions, regulatory jurisdiction and evaluates impacts (both direct and indirect) of the alternatives on state and federally listed rare species.

4.15.1.1 Resource Definition

State-listed (rare) species are protected under the Massachusetts Endangered Species Act (MESA) of 1990,[1] and are classified as Endangered, Threatened, or Species of Special Concern. An "Endangered" species is one that is in danger of extinction throughout all or a significant portion of its range within Massachusetts. A "Threatened" species is one that is likely to become endangered in Massachusetts in the foreseeable future. Species of Special Concern are those species that biological research has documented to have suffered a decline that could threaten the species if the decline continues unchecked, or those species that occur in such small numbers or with such a restricted distribution that they could easily become threatened within the Commonwealth.

The Federal Endangered Species Act (ESA) of 1973[2] defines an endangered species as "any species which is in danger of extinction throughout all or a significant portion of its range." The ESA also defines a threatened species as "any species which is likely to become an endangered species within the foreseeable future throughout all or a significant portion of its range." The ESA[3] protects species that are listed as endangered or threatened on a national basis.

4.15.1.2 Regulatory Context

Federal and state laws protect rare plants and animals and their critical habitats. The following describes the federal and state regulations that protect rare species and, in some instances, their habitats.

Federal Endangered Species Act

The ESA of 1973, (16 USC 1531 *et seq.,* as amended),[4] authorizes the determination and listing of species as Endangered and Threatened and prohibits unauthorized taking, possession, sale, and transport of endangered species. Section 7 of the Act[5] requires federal agencies to ensure that any action authorized, funded, or carried out by a federal agency is not likely to jeopardize the continued existence of listed species or to modify their critical habitat. The U.S. Fish and Wildlife Service (USFWS) administers the Act. The National Oceanic and Atmospheric Administration's National Marine Fisheries Service (NOAA Fisheries), a division of the U.S. Department of Commerce, is the lead federal agency responsible for the stewardship of the nation's offshore living marine resources and their habitat. NOAA Fisheries manages, conserves, and protects fish, whales, dolphins, sea turtles and other living creatures in the ocean, and administers the Endangered Species Act for species within its purview.

[2] Endangered Species Act of 1973, (16 U.S.C. 1531 et seq., as amended) United States Fish and Wildlife Service.
[3] Endangered Species Act of 1973, (16 U.S.C. 1531 et seq., as amended) United States Fish and Wildlife Service.

[4] Endangered Species Act of 1973, Section 7(16 USC 1531 et seq., as amended), United States Fish and Wildlife Service.
[5] Ibid.

Massachusetts Endangered Species Act

Massachusetts enacted MESA in 1990. The Act (M.G.L. Chapter 131A) and its regulations (321 CMR 10.00) prohibit the "taking" of any state-listed rare plants and animals unless specifically permitted for scientific, educational, or propagation purposes, or where a Conservation Permit is issued. "Take" includes protection of rare species habitat, and is defined as, "*in references to animals to harass, harm, pursue, hunt, shoot, hound, kill, trap, capture, collect, process, disrupt the nesting, breeding, feeding or migratory activity or attempt to engage in any such conduct, or to assist such conduct, and in reference to plants, means to collect, pick, kill, transplant, cut or process or attempt to engage or to assist in any such conduct. Disruption of nesting, breeding, feeding or migratory activity may result from, but is not limited to, the modification, degradation or destruction of Habitat*."

The regulations (321 CMR 10.05) state that "All State Agencies shall review, evaluate, and determine the impact on Endangered, Threatened and Special Concern species or their habitats… and use all practicable means and measures to avoid or minimize damage to such species or their habitats." State agencies are responsible for demonstrating to the Secretary that all practicable means and measures to protect rare species and their habitats have been incorporated into the project design. The Massachusetts Department of Fish and Wildlife's (DFW) Natural Heritage and Endangered Species Program (NHESP) is the agency responsible for ensuring compliance with MESA. A proposed project that would result in a "take," requires a Conservation and Management Permit from the NHESP.

State-listed (rare) species are protected under the MESA of 1990,[6] and are classified as Endangered, Threatened, or Species of Special Concern. An "Endangered" species is one that is in danger of extinction throughout all or a significant portion of its range within Massachusetts. A "Threatened" species is one that is likely to become endangered in Massachusetts in the foreseeable future. Species of Special Concern are those species that biological research has documented to have suffered a decline that could threaten the species if the decline continues unchecked, or those species that occur in such small numbers or with such a restricted distribution that they could easily become threatened within the Commonwealth.

Massachusetts Wetlands Protection Act

The Massachusetts Wetlands Protection Act Regulations (WPA [310 CMR 10.00 et seq.]) state that proposed projects that alter estimated rare wildlife habitat shall not be permitted to have any short-term or long-term adverse effects on the habitat of the local population of that species. The regulations only apply to proposed projects that would alter the habitat of a rare animal species occurring in a wetland resource area for which an occurrence has been entered into the official NHESP database. Rare plants are not regulated under the WPA. The NHESP maintains an atlas of Estimated Habitat for state-listed rare species, which was last updated in 2008.

4.15.1.3 Regulatory Coordination

On December 4, 2008, a letter was submitted by the applicant to the NHESP requesting site-specific rare species information. The list of species was provided by NHESP on January 8, 2009.[7] On December 4, 2008 a letter was submitted to the NMFS requesting information on any threatened and endangered fisheries resources located within the project area. NMFS response was received on January 12, 2009 with the determination that there are no federally endangered fisheries resources within the study area.

[6] Massachusetts Endangered Species Act of 1990 (321 CMR 10.00: M.G.L. c. 131A.), Natural Heritage Endangered Species Program.
[7] NHESP letter dated January 8, 2009.

Subsequent to the publication of the DEIS, the New York Bight Distinct Population Segment of Atlantic sturgeon (*Acipenser oxyrinchus oxyrinchus*) was listed as an endangered species under the ESA by the NMFS on April 6, 2012.[8] However, the NMFS stated in its May 13, 2013 response letter it is unlikely that any species listed under their jurisdiction will be exposed to any direct or indirect effects of the proposed South Coast Rail project, including the Atlantic sturgeon. The above correspondence is included in Appendix 4.15-A.

The Certificate of the Secretary of Environmental Affairs on the ENF dated April 3, 2009,[9] also requested the applicant to consult with NHESP to discuss additional endangered species habitat assessments and surveys required in order to adequately quantify relative impacts of the alternatives. MassDOT has consulted with the NHESP subsequent to the DEIS/DEIR concerning the methodology for evaluating existing conditions and species impacts to state-listed threatened and endangered species.

The South Coast Rail project would result in a “take” of state-listed animals if the reconstruction of the rail system would directly harm state-listed animals, or if the project would disrupt breeding or migratory activity through the loss of habitat or loss of migratory pathways. The reconstruction of the rail system would result in a “take” of plant species where the project would result in the loss of habitat occupied by these species

The NHESP has determined that constructing the South Coast Rail project could have an adverse effect (a “take”) on three state-listed species: Blanding’s turtle (*Emydoidea blandingii*), eastern box turtle (*Terrapene carolina carolina*), and blue-spotted salamander (*Ambystoma laterale*). NHESP has determined, based on the preliminary design, that reconstruction of the track in the Southern Triangle would not constitute a “take” under MESA.

4.15.2 **Existing Conditions**

4.15.2.1 Regional Overview of Existing Conditions

This chapter includes a general description of the study area for threatened and endangered species and lists the rare species found within the polygons of Estimated and Priority Habitats that intersect or are adjacent to it.

Study Area

The study area for the assessment of threatened and endangered species is the portion of the South Coast region that is adjacent to or crossed by the Stoughton and/or Whittenton Alternatives south of Canton Junction. Within the study area, the alignment of each alternative intersects areas that contain wetlands and ecosystems that have been mapped as Priority and/or Estimated Habitat for rare species. Maps of the alternatives were examined for areas of mapped habitat that were intersected by or adjacent to a 100-foot buffer, measured from the centerline of the proposed railroad tracks of the Build Alternatives. Areas of important biodiversity value include the Hockomock Swamp, Pine Swamp, Assonet Cedar Swamp, Acushnet Cedar Swamp, and Forge Pond (Figure 4.15-1 through 4.15-2). In some cases, these ecosystems are within ACECs such as the Hockomock Swamp ACEC, (Figure 4.14-2). ACECs are described in Chapter 4.10, *Protected Public Open Space and Areas of Critical Environmental Concern*.

[8] Federal Register: February 6, 2012 (Volume 77, Number 24, page 5880-5912), Endangered and Threatened Wildlife and Plants; Threatened and Endangered Status for Distinct Population Segments of Atlantic Sturgeon in the Northeast Region.

[9] Executive Office of Transportation and Public Works, South Coast Rail Environmental Notification Form, November 2008.

Rare species represent one of the most sensitive elements of biodiversity. Other elements of biodiversity are addressed in Chapter 4.14, *Biodiversity, Wildlife, and Vegetation.*

The Stoughton and Whittenton Alternatives would utilize the Northeast Corridor between Canton Junction and South Station in Boston. However, the Northeast Corridor was not included in the study area because no construction/habitat disturbance would be required along the Northeast Corridor. Northeast Corridor is already electrified, thus catenary construction would not be needed in this area under the electric variants of the Stoughton and Whittenton Alternatives. In addition, there is no potential for indirect effects (noise disturbance, water quality impacts) on habitat along the Northeast Corridor because the South Coast Rail project trains would be a small incremental change relative to the heavy existing Northeast Corridor passenger and freight train traffic.

Priority and Estimated Habitats

A review of the 2008 Edition of the Massachusetts NHESP Natural Heritage Atlas was performed to identify areas where the South Coast Rail alternatives cross Priority Habitats of Rare Wildlife and Estimated Habitats of Rare Species. Priority Habitat is based on the known geographical extent of habitat for all state-listed rare species, both plants and animals, and pertains to MESA. Maps are used for determining whether or not a proposed project must be reviewed by the NHESP for MESA compliance.[10] Estimated Habitats are a sub-set of the Priority Habitats that are based on the geographical extent of habitat of state-listed rare wetlands wildlife. Each mapped Priority and Estimated Habitat is assigned a unique identification number that the Natural Heritage Program uses to track information related to each Priority Habitat and Estimated Habitat polygon.

Table 4.15-1 lists the Priority and Estimated Habitat polygon identification numbers that intersect or are adjacent to the project corridors. Table 4.15-2 lists the state-listed species that may be found within and/or adjacent to the South Coast Rail alternatives. This list is based on information provided by the NHESP on January 8, 2009,[11] in response to a formal request for a detailed list of species found within these Estimated and Priority Habitats (Figures 4.15-3). The above correspondence is included in Appendix 4.15-A.

The NHESP letter listed two Priority Habitat polygons (PH924/EH753 and PH926/EH755) that provide habitat for the state and federally endangered roseate tern (*Sterna dougalli*) and the state-special concern common tern (*Sterna hirundo*). These species and their Priority Habitat were excluded from both tables because these polygons are not adjacent to the 100-foot buffer of the project corridor and are separated from the New Bedford Main Line by major developed areas (Figure 4.15-8).

Table 4.15-1 Priority and Estimated Habitats Within or Adjacent to the Study Area

Project Alternative (segments)	Priority Habitat (PH) (Identification #)	Estimated Habitat (EH) (Identification #)	Location
Southern Triangle (New Bedford Main Line) (see Figures 4.15-4-8)	1093	951	Assonet Cedar Swamp, Mass Audubon Great Cedar Swamp, Assonet River, Cedar Swamp River, Cotley River
Southern Triangle (New Bedford Main Line) (see Figure 4.15-4-8)	1158	372	Apponquet Regional High School, Cedar Swamp River
Southern Triangle (New Bedford Main Line) (see Figures 4.15-4-8)	1349	1	Acushnet Cedar Swamp
Southern Triangle (Fall River Secondary) (see Figure 4.15-9-11)	1093	951	Assonet River
Stoughton Alternative (Stoughton Line) (see Figures 4.15-12-15)	1392	59	Hockomock Swamp ACEC, Hockomock Swamp WMA
Stoughton Alternative (Stoughton Line) (see Figure 4.15-12-15)	1297	1077	Pine Swamp
Whittenton Alternative (Whittenton Branch) (see Figure 4.15-16-17)	261	153	Tributary to Mill River

Table 4.15-2 Potential State-Listed Species Documented Within PH and EH Polygons Adjacent to the Project Alternatives

Species	Status[1]	Priority (PH) and Estimated (EH) Habitat[2]
Amphibians		
Blue-Spotted Salamander (*Ambystoma laterale*)	SC	PH1392/EH59
Reptiles		
Blanding's Turtle (*Emydoidea blandingii*)	T	PH1392/EH59;
Eastern Box Turtle (*Terrapene carolina carolina*)	SC	PH1392/EH59; PH1349/EH1; PH261/EH153
Crustacean		
Coastal Swamp Amphipod (*Synurella chamberlaini*)	SC	PH1349/EH1
Dragonflies		
Mocha Emerald (*Somatochlora linearis*)	SC	PH1093/EH951
Butterflies and Moths		
Hessel's Hairstreak *(Callophrys hesseli)*	SC	PH1349/EH1
Pale Green Pinion Moth (*Lithophane viridipalle*)	SC	PH1349/EH1
Water-Willow Stem Borer Moth (*Papaipema sulphurata*)	T	
Plants		
Gypsywort (*Lycopus rubellus*)	E	PH1392
Long-Leaved Panic-Grass (*Panicum rigidulum ssp. pubescens*)	T	PH1158

E = State Endangered, T =State Threatened, SC = State Special Concern. Fed E = Federal Endangered
Priority and Estimated Habitats (PH1158/EH372) have data sensitive species that were not released by NHESP.

Other State-Listed Species

The list of state-listed species (Table 4.15-2) provided by the NHESP includes only those species likely to be found adjacent to the alignment corridors of the alternatives. Other species may occur in the larger polygons, or within the contiguous ACECs, that are not listed in this table. Habitat for these additional

species may occur in areas adjacent to the alignment corridors. Based on information on the Massachusetts Department of Conservation and Recreation (DCR) ACEC Program website and the NHESP's lists of rare species by town, these could include freshwater mussels (tidewater mucket [*Leptodea ochracea*], triangle floater [*Alasmidonta undulata*], and eastern pondmussel [*Ligumia nasuta*]); damselflies (New England bluet [*Enallagma laterale*]); birds (American bittern [*Botaurus lentiginosus]*); amphibians (eastern spadefoot [*Scaphiopus holbrookii*]); and plants (Eaton's beggar-ticks [*Bidens eatonii*]; Long's bitter cress [*Cardamine longii*], cat-tail sedge [*Carex typhina*], round-fruited false-loosestrife [*Ludwigia sphaerocarpa*], climbing fern [*Lygodium palmatum*]*,* Philadelphia panic-grass [*Panicum philadelphicum*], pale green orchids [*Platanthera flava* var*. herbiola*], and grass-leaved ladies tresses [S*piranthes vernalis*]).

4.15.2.2 Rare Species Description and Habitat Requirements

This section includes a description of the range, habitat requirements, and areas where rare species are found within the polygons of Estimated and Priority Habitats that intersect or are adjacent to the study area. It also includes a summary of their breeding and nesting behavior. Unless otherwise indicated, the information below is based on the NHESP fact sheets for each species (www.mass.gov/dfwele/nhesp/species-info/nhfacts), accessed April 13, 2012.

Blue-Spotted Salamander (*Ambystoma laterale;* State Special Concern)

The NHESP database indicates that this species is present within the Hockomock Swamp polygon (PH1392/EH59). Populations of pure blue-spotted salamanders occur north of the hybridization zone with Jefferson salamanders (*A. jeffersonianum*). The area of populations of pure blue-spotted salamanders and hybrids extends from the Canadian Maritime Provinces, south along the Atlantic coast to northern New Jersey. The range extends westward through to northern Indiana and northeastern Illinois, through most of Wisconsin, eastern Minnesota and the southern half of Ontario. In Massachusetts, they occur predominantly within Middlesex and Essex Counties and in the adjacent eastern towns of Worcester County. Some occurrences are also noted within Bristol and Plymouth Counties. In general, Jefferson-blue-spotted complex salamanders found east of the Connecticut River are more likely to be blue-spotted salamanders. There are 102 towns in Massachusetts where blue-spotted salamanders have been observed. Over 172 occurrences have been documented since 1981, as well as 27 historic occurrences that were documented prior to 1981.

Blue-spotted salamanders require moist, moderately shaded environments; they favor northern hardwood/hemlock forests in glaciated areas with depressions available for seasonal flooding. Vernal pools, or temporary ponds, are necessary for reproduction and need to be full of dead and decaying leaves for cover and have overhanging bushes or grass for egg deposition. Roadside drainage ditches, small kettle holes, and temporary pasture ponds also provide habitat when flooded in the spring. Adults reside most of the year beneath leaf litter or underground to a depth of one meter, usually within 500 meters of their breeding pond. The brief breeding season lasts from mid-March to late April. Eggs are often laid singly or in a small egg mass, which cling lightly to overhanging vegetation or fall to the bottom of the pond.

Intensive rare species surveys conducted in 2001 identified a large population of blue-spotted salamanders in Hockomock Swamp, primarily south of Foundry Street, and confirmed that blue-spotted salamanders breed in vernal pools adjacent to the railroad berm in this area. A single blue-spotted salamander was trapped in the area immediately north of Foundry Street. The habitat of blue-spotted salamander was found to extend from approximately 650 feet north of Foundry Street to approximately

3,500 feet south of the power line. The adjacent forested uplands and wetlands provide suitable non-breeding habitat for this species.

Wood Turtle (*Clemmys insculpta*; State Special Concern)

The NHESP recently determined that habitat of the wood turtle occurs near the Southern Triangle. Due to its location in relation to the proposed railway alignment an analysis of impacts to this state-listed species was not included in this section.

Ringed Boghaunter (*Williamsonia lintneri*; State Threatened)

The NHESP has recently determined that habitat of ringed boghaunter dragonfly occurs near the Southern Triangle. However, due to its location in relation to the proposed railway alignment an analysis of impacts to this state-listed species was not included in this section.

Blanding's Turtle (*Emydoidea blandingii*; State Threatened)

The NHESP database indicates that this species is present within the polygons that include the Hockomock Swamp (PH1392/EH59). Blanding's turtles are found primarily in the Great Lakes region, extending to Kansas. Several smaller, disjunct populations occur in the East: in southern Nova Scotia, in an arc from eastern Massachusetts through southeastern New Hampshire to southern Maine, and in the New York's lower Hudson Valley. These populations (except those in New Hampshire) are all listed as threatened or endangered at the state or provincial level.

In Massachusetts, Blanding's turtles use a variety of wetland and terrestrial habitats. Blanding's turtles have been observed in seasonal pools, marshes, scrub-shrub wetlands, and open uplands.[12] Habitat use appears to vary according to the individual and the amount of precipitation, with more upland use during dry years.[13] Wetlands are used for overwintering during their inactive season (November to March).

Courtship and mating takes place during the spring and early summer and typically occurs in water. Females will remain in wetland or vernal pool habitat until they begin nesting. The majority of nesting occurs in June in open areas with well-drained loamy or sandy soils, such as dirt roads, powerline corridors, residential lawns, gravel pits, and early successional fields.

Field studies undertaken in 2009 confirmed Blanding's turtle use of the power line right-of-way east of Route 138. Habitat potentially used by this species along the Stoughton Alternative, as reported by NHESP, extends from Purchase Street in Easton to the Hockomock Swamp south of the power line right-of-way.

Eastern Box Turtle (*Terrapene carolina Carolina*; State Special Concern)

The NHESP database indicates that this species is present within the polygons that include the Assonet Cedar Swamp (PH1093/EH951), Acushnet Cedar Swamp (PH1349/EH1), wetlands and along the Whittenton Branch corridor (PH261/EH153). The Eastern box turtle's range is from southeastern Maine to northern Florida to Michigan, Illinois, and Tennessee. They occur throughout Massachusetts, but are more heavily concentrated in the southeastern section of the state.

[12] Sievert, P.R., Compton B.W., and M. Grgurovic. 2003. Blanding's Turtle (*Emydoidea blandingii*) conservation plan for Massachusetts. Pages 161. Report for Natural Heritage and Endangered Species Program. Westborough, MA.

[13] Joyal, L.A., McCollough, M. and J.M.L. Hunter. 2000. Population structure and reproductive ecology of Blanding's Turtle (Emydoidea blandingii) in Maine, near the Northeastern edge of its range. Chelonian Conservation and Biology 3:580-588.

In Massachusetts, Eastern box turtles inhabit many types of terrestrial habitats: both dry and moist woodlands, brushy fields, thickets, marsh edges, bogs, swales, fens, stream banks, and well-drained bottomland. Mating is opportunistic and may take place anytime between April and October. Females nest in June or early July and can travel great distances to find appropriate nesting habitat. Field studies in 2001 confirmed the presence of eastern box turtles in the Hockomock Swamp, south of the former Raynham Greyhound Park.

Coastal Swamp Amphipod (*Synurella chamberlaini*; State Special Concern)

The NHESP database indicates that this species is present within the Acushnet Cedar Swamp polygon (PH1349/EH1). In Massachusetts, the coastal swamp amphipod is known to be present in Dartmouth and New Bedford. Elsewhere in New England, records exist in southeastern Maine, Rhode Island, and eastern Connecticut. Its range also extends south from Maryland to South Carolina along the Middle Atlantic Coastal Plain.

In Massachusetts, coastal swamp amphipod is found in heavily vegetated, low-gradient, coastal wetland outlet streams of red maple and white cedar swamps in the Buzzards Bay moraine deposits.[14] This species can also be found in emergent marshes adjacent to these outlet streams. Elsewhere, the coastal swamp amphipod is known to inhabit small streams, bogs, ponds, and ditches.[15]

This species has an annual life cycle. In winter and spring, reproductive females brood up to 65 eggs per clutch.[16] In general, amphipods aggregate in large numbers and remain hidden in organic debris or among beds of aquatic vegetation.

Mocha Emerald (*Somatochlora linearis*; State Special Concern)

The NHESP database indicates that this dragonfly is present within the Assonet Cedar Swamp polygon (PH1093/EH951). The mocha emerald is distributed throughout the eastern United States from Massachusetts south to Florida and west to Michigan, Iowa, and Texas. In New England, the mocha emerald is recorded from Connecticut and Rhode Island, north only to Massachusetts. The species is known to inhabit about nine locations, all confined to eastern Massachusetts.

In Massachusetts, the mocha emerald has been found most often away from breeding habitats in fields and forest clearings. However, many of these areas are adjacent to habitats that, based on observations elsewhere in this species range, are appropriate breeding sites for the mocha emerald. Breeding sites for this species are small to medium-sized streams that flow through woods or swamps. A sand or gravel bottom may be an important habitat characteristic, since females prefer to oviposit (place their eggs) in this type of substrate. In addition to Assonet Cedar Swamp, Pierce Brook and the Cedar Swamp River (Assonet River) may provide suitable habitat for this species.

The mocha emerald has been recorded in Massachusetts from early July through mid-August. Information from nearby areas for this species extends the flight season from late June through early September. As in other regions where this species occurs, breeding in Massachusetts probably occurs from early July through August.

[16] Holsinger, J.R. 1972. The freshwater amphipod crustaceans (Gammaridae) of North America. United States Environmental Protection Agency. Biota of Freshwater Ecosystems. Identification Manual 5: 1-89.

Hessel's Hairstreak (*Callophrys hesseli*; State Special Concern)

The NHESP database indicates that this butterfly is present within the Assonet Cedar Swamp polygon (PH1093/EH951) as well as the Pine Swamp polygon (PH129/EH1077). Hessel's hairstreak is distributed in scattered colonies along the Atlantic coastal plain from southern Maine to the Florida panhandle and southeastern Alabama. The greatest density of colonies is found in southern New Jersey, southeastern Massachusetts, and Rhode Island. In Massachusetts, most colonies are concentrated in southern Worcester, Norfolk, Bristol, and Plymouth Counties.

Hessel's hairstreak exclusively inhabits Atlantic white cedar swamps and bogs. This hairstreak has also been recorded in the Hockomock Swamp. Adults feed on nectar from swamp milkweed (*Asclepias incarnata*), shadbush (*Amelanchier alnifolia*), sand myrtle (*Leiophyllum buxifolium*), sweet pepperbush *(Clethra alnifolia)*, highbush blueberry *(Vaccinium corymbosum)*, buttonbush (C*ephalanthus occidentalis*), and dogbane (*Apocynum androsaemifolium*). It occurs only in or adjacent to Atlantic white cedar swamps and associated barrens. Males perch at the tops of white cedars in spring to seek receptive females, and females lay single eggs on the terminal shoots of white cedars. Larvae feed and develop into the pupal stage on the leaves of the host trees. Potential habitat along the project corridor for Hessel's hairstreak includes Atlantic white cedars established on the sideslopes of the embankment within Assonet Cedar Swamp, Pine Swamp, and Hockomock Swamp, and the extensive areas of Atlantic white cedar swamp within these wetlands.

Pale Green Pinion Moth (*Lithophane viridipallens*; State Special Concern)

The NHESP database indicates that this species is present within the Acushnet Cedar Swamp polygon (PH1349/EH1). The pale green pinion moth is spottily distributed along the coastal plain from southern New England south to New Jersey, with a more continuous range along the coastal plain from southern New Jersey south to Florida and west to Texas. In Massachusetts, this species occurs on the coastal plain in the southeast part of the state. In Massachusetts, the pale green pinion moth inhabits acidic, shrubby wetlands on the coastal plain, including wooded swamps, shrub swamps, shrubby bogs, and on the shores of coastal plain ponds. Suitable habitat occurs along the rail line through the Acushnet Cedar Swamp.

Adult moths emerge in October and early November and overwinter, flying on warm nights in late winter and early spring. Eggs are laid in spring on the larval host plants, which have not been documented in Massachusetts, but probably include a variety of acidic wetland shrubs such as holly (*Ilex* spp.), chokeberry (*Aronia* spp.), sweet pepper-bush, swamp-fetterbush (*Leucothoe racemosa*), maleberry (*Lyonia ligustrina*), and highbush blueberry.

Water-Willow Stem Borer (*Papaipema cataphracta*; State Threatened)

The NHESP database indicates that this moth is present within the Acushnet Cedar Swamp polygon (PH1349/EH1). The water-willow stem borer is endemic to southeastern Massachusetts, occurring in Plymouth and Bristol Counties as well as on Cape Cod and the offshore islands.

The water-willow stem borer inhabits shallow portions of coastal plain wetlands, in the shallowest portions of vernal pools, seasonally flooded swamps, abandoned cranberry bogs, and along upland edges of streams and ponds, where its obligate host water-willow *(Decodon verticillatus)* occurs. No specific surveys have been undertaken for Decodon, but it is likely that suitable habitat occurs near the rail line through Acushnet Cedar Swamp.

The water-willow stem borer is a nocturnal moth (noctuid) with a wingspan of 1.3 to 1.5 inches. Females lay eggs in late fall at the base of water-willow clumps, and when larva emerge the following spring, they bore into a water-willow stem, where they spend the summer. The larva pupate inside the stem in early fall, and upon emergence, look for a mate, reproduce, and die.

Gypsywort (*Lycopus europaeus*; State Endangered)

The NHESP database indicates that this plant is present within the Hockomock Swamp polygon (PH1392). Gypsywort is distributed from eastern Massachusetts southward to Florida and eastern Texas on the Coastal Plain, and northwards through the Mississippi River basin to southern Michigan. It is only sporadically found in the area between the Mississippi and the Atlantic Coast. Gypsywort is a coastal plain pond species occurring in smaller ponds with mucky to peaty soils, and is often associated with Plymouth gentian *(Sabatia kennedyana)*. Historically, it also was known from borders of ponds in Fall River and Westport.

Plant surveys conducted in 2001 identified a small population of gypsywort in open wetlands associated with Black Brook in the Hockomock Swamp, south of the power line right-of-way, within 15 feet of the existing railroad berm.[17]

Long-Leaved Panic-Grass (*Panicum rigidulum ssp. pubescens*; State Threatened)

This species is known to occur within the polygon that includes a wooded swamp area and the Cedar Swamp River (PH1158). The long-leaved panic-grass is associated with coastal plain pond shore communities.[18] No suitable habitat for this species has been identified in proximity to the rail right-of-way.

4.15.2.3 Rare Species Studies

This section describes specific rare species studies conducted in 2001 and 2008 along the Stoughton Line. These studies were undertaken to determine rare species occurrence along areas of this alternative where there is currently no track because NHESP determined that these were areas of concern.

In support of the 2002 Fall River/New Bedford Commuter Rail Extension EIR, a study was conducted in the spring and summer of 2001 to determine rare species occurrences in the Hockomock and Pine Swamps. The study methodology was developed in consultation with, and approved by, the NHESP and conducted under a Scientific Collecting Permit issued by the DFW. The rare species study area was defined as the area within 600 feet of the right-of-way centerline, extending from a point approximately 1,500 feet north of Foundry Street in Easton to Bridge Street in Raynham (Hockomock Swamp), and from King Philip Street to East Brittania Street in Raynham (Pine Swamp). This study area was divided into five segments, generally separated by roads or other features and with distinct vegetation types. Markers, consisting of numbered yellow plastic flagging and “tuft” stakes, were installed at 100-foot intervals to enable the study team to precisely locate rare species. The survey methods used included visual observation during “big night” events, drift fencing and pit traps, turtle hoop traps, radiotelemetry of turtles, invertebrate surveys, and rare plant surveys. Turtles equipped with radio transmitters were tracked daily until June 30, 2001 and then tracked weekly until September 30, 2001.

[17] New Bedford/Fall River Commuter Rail Extension Rare Species Study – Final Report. Prepared by VHB for MBTA, January 31 2002.
[18] Grass Manual on the Web, Utah State University. http://herbarium.usu.edu/webmanual, accessed April 13, 2012.

The 2001 study also included surveys for state-listed plant species and potential state-listed invertebrate habitats, based on host plant distributions.

In the spring of 2008, a survey using hoop traps, visual nesting surveys, and radiotelemetry was also conducted in Easton to locate Blanding's turtles. The following is a summary of the survey results for the blue-spotted salamander, eastern box turtle, and Blanding's turtle. No additional site-specific studies for state-listed species were undertaken at the direction of NHESP as existing information on species distributions was deemed adequate to evaluate impacts and develop a Conservation Management Plan (CMP).

Blue-Spotted Salamander (*Ambystoma laterale*)

The rare species study conducted in the spring and summer of 2001 documented a substantial population of blue-spotted salamanders that crossed the right-of-way in both directions. Blue-spotted salamanders were captured in 31 of the drift fence arrays, including 85 percent (11) of the drift fence arrays in a segment north of the powerline and 76 percent (16) of the drift fence arrays in a segment south of the powerline. No blue-spotted salamanders were found in Pine Swamp or in the Hockomock ACEC, south of the former Greyhound Park. One was captured north of Foundry Street.

Animals were captured in approximately equal numbers on both sides of the right-of-way. There did not appear to be any significant directional component to the population movement.

During the "big night" event (April 6, 2001), blue-spotted salamanders were observed in almost equal numbers north and south of the powerlines (27 and 31, respectively). The majority of animals to which a movement direction could be determined were moving across the right-of-way from west to east.

A total of 549 blue-spotted salamanders from a large population were captured in pit traps. An additional 58 animals were observed during visual night surveys. The majority of these animals were captured during the first two weeks of the study, with elevated numbers also observed in mid-May (Table 4.15-3).

Table 4.15-3 Blue-Spotted Salamander (*Ambystoma laterale*) Capture–by Date (2001)

Date	Total Number
March 31-31	64
April 1-15	293
April 16-30	41
May 1-15	8
May 16-31	134
June 1-15	9
June 16-30	0

Eastern Box Turtle (*Terrapene carolina carolina*)

One eastern box turtle was captured in 2001 and fitted with a radio transmitter. This turtle (designated B1) was captured in the upland forest west of the right-of-way, north of Bridge Street in Raynham. Turtle B1 was captured initially on May 11, 2001. It was tracked in the uplands west and north of the initial capture location until May 21, then relocated four weeks later (June 20) in the same area. The turtle was apparently west of the right-of-way, out of receiver range, during this period.

On June 30, 2001, the turtle research team documented the locations of turtle nests within the study area that had been excavated by predators. It was not possible to accurately determine the species of turtle; therefore, these data indicate the locations where all turtle species (spotted, snapping, and painted) nest within the study area. Turtle nests were found in six locations within the Hockomock Swamp. Generally, nests were found in the softer substrate at the edges of the right-of-way. More specific locations of turtle nests have been submitted to the NHESP.

The 2001 rare species study determined that eastern box turtles are infrequently found within the Hockomock Swamp ACEC, and that this species was found to occur only within upland forested areas south of the former Greyhound Park. The 2008 Blanding's turtle study conducted in the Hockomock Swamp (south of Foundry Street) found no eastern box turtles during the nest surveys.

Blanding's Turtle (*Emydoidea blandingii*)

The extensive studies conducted in 2001 found no evidence of Blanding's turtles in the surveyed areas. However, NHESP records show several individuals north and east of the right-of-way in Easton.

In June 2008, habitat evaluations and surveys along the Stoughton Alternative were conducted for the state-Threatened Blanding's turtle. This survey was performed because the NHESP database indicated the presence of Blanding's turtles in the vicinity of the existing railroad bed. Surveys and habitat evaluations were conducted along an approximately 1.3-mile section of an existing railroad bed and a 1.2-mile section of an existing powerline easement within the Hockomock Swamp in Easton. The area surveyed extends from approximately 0.16 mile north of Foundry Street to 1.14 miles south of Foundry Street along the railroad bed. The purpose of this study was to verify the presence of Blanding's turtles, evaluate their use of aquatic habitats and upland nesting habitats, and to start establishing a subpopulation of Blanding's turtles outfitted with radio transmitters.

The Blanding's turtle study area is almost entirely within land managed by the DFW's Hockomock Swamp Wildlife Management Area. Wetland and upland areas adjacent to the proposed project are mapped by the NHESP (2008) as Priority Habitat (PH1392) and Estimated Habitat (EH59) for the Blanding's turtle. Mapped habitat areas extend from the northern extent of the study area (southern boundary of the Easton Country Club), south approximately 3.7 miles to I-495 and from Prospect Street and Howard Street west of the railroad bed to beyond Route 24 east of the railroad bed.

The survey methodology included:

- Trapping in specially designed sardine-baited hoop traps, (3- and 4-foot diameter, 1-inch mesh)
- Repeated transect and/or meander surveys of suitable habitat on foot
- Basking surveys from shore with binoculars
- Meander surveys through suitable nesting habitats

One female Blanding's turtle (designated EB-1) was observed east of Route 138 and outfitted with a radio transmitter. One nest was found approximately 2 meters from the location where EB-1 was observed. Other recent observations documented by NHESP have been east of the rail corridor as well.

Deep aquatic habitats typically associated with this species were limited within the survey area and were primarily associated with Black Brook and a few isolated pockets within the greater Hockomock Swamp area. Areas of suitable foraging habitat (e.g., vernal pools), large expanses of unfragmented open space for migration, and suitable nesting habitats were observed during the nesting surveys. Potential Blanding's turtle habitats were also investigated from a broader landscape perspective; this investigation was primarily based on interpretation of 2005 MassGIS color aerial photographs with field verification of some areas.

A variety of landscape features are present within the vicinity of the railroad bed including commercial and residential development, paved roads, a school, a landfill, golf courses, cranberry bogs, a power line easement, and forested uplands. Wetland habitat types in the study area consist of a variety of deciduous and coniferous palustrine forested (PFO) wetland systems, scrub-shrub (PSS) and emergent (PEM) wetland systems, certified vernal pools, and a perennial, unconsolidated bottom riverine system (Black Brook). The majority of suitable aquatic habitat occurs east of the rail corridor, in the vicinity of the cranberry bog complex north of Foundry Street and in the Hockomock Brook and Hockomock Swamp east of Route 138. No suitable aquatic habitat occurs west of the rail corridor north of Foundry Street. NHESP has indicated that they believe that Blanding's turtles use habitats east and west of the rail corridor from the powerlines north through the golf course area.

In 2009 radio-telemetry was conducted in several site visits down to the Hockomock Swamp in Easton, MA with the primary goal of re-capturing the female Blanding's turtle that was outfitted with a transmitter in June 2008, and removing that transmitter. The female Blanding's turtle covered significant distances (approximately 3 miles over the 6 point observations collected between June 2008 and July 2009) and was hand captured on July 5, 2009 within 100 feet of her June 2008 nesting location. The survey was submitted to NHESP.

Rare Plant Survey

Rare plant species recorded for the Hockomock Swamp ACEC, according to NHESP, include:

- *Ludwigia sphaerocarpa* (coastal plain pondshores)
- *Lycopus rubellus* (coastal plain pondshores)
- *Scirpus longii* (coastal plain pondshores, fens)
- *Sabatia kennedyana* (coastal plain pondshores)
- *Utricularia biflora* (coastal plain pondshores)

The entire alignment within the Hockomock Swamp segment of the right-of-way (including all areas within 100 feet of the right-of-way) was investigated by a qualified plant taxonomist in 2000-2001 to determine if potential habitats for state-listed plant species occur within or adjacent to the corridor. Three wetland areas within 100 feet of the railroad right-of-way were investigated to determine if these provide coastal plain pondshore or fen habitats, and if any of these or other state-listed species were present. Detailed location information has been provided to the NHESP.

None of the wetlands adjacent to the right-of-way are coastal plain ponds or fens. The Black Brook wetland, located adjacent to the right-of-way and south of the powerline, contains a small population of

gypsywort, a state-listed plant. This species was found within 15 feet of the right-of-way. No other state-listed species were found in areas adjacent to the right-of-way.

Habitat of State-Listed Invertebrates

Areas along the Stoughton Line, particularly within the Hockomock Swamp and Pine Swamp, were surveyed in the spring and summer of 2000 and 2001 to determine if suitable habitat for state-listed invertebrates is present, based on the presence of host plant species. This survey found that suitable habitat (Atlantic white cedars (*Chamaecyparis thyoides*) and water-willow) for two state-listed insects is present.

Potential habitat along the project corridor for Hessel's hairstreak includes Atlantic white cedars that have become established on the sideslopes of the embankment within Hockomock Swamp and Pine Swamp as well as the extensive areas of Atlantic white cedar swamp within these wetlands.

Two areas of water-willow have been identified along the right-of-way in the Hockomock Swamp. The first is in the southern portion of the ponding area associated with Certified Vernal Pool 1711 (within Wetland EA37). The second is in a pond in Wetland EA37, west of the railroad embankment, approximately 900 feet north of the former Greyhound Park.

4.15.2.4 Existing Conditions within the Study Corridor

This section lists and describes the Priority and Estimated Habitats that are crossed by the alternatives and the state-listed species associated with each.

Southern Triangle (Common to All Rail Alternatives)

The Southern Triangle section of the project area includes the existing active Fall River Secondary and the New Bedford Main Line. Portions of these rail lines are within mapped Priority and Estimated Habitats. Based on the 2008 NHESP Atlas, the New Bedford Main Line crosses three NHESP Priority and Estimated Habitats (PH1093/EH951, PH1158/EH372, and PH1349/EH1), including the Cotley River, Cedar Swamp River, Assonet Cedar Swamp/Great Cedar Swamp, and the Acushnet Cedar Swamp (Figures 4.15-4-8).

The Fall River Secondary crosses one NHESP Priority and Estimated Habitat (PH1093/EH951). This section of the right-of-way includes several smaller wetlands along the Assonet River (Figures 4.15-9). Table 4.15-4 lists the species found within these Priority and Estimated Habitats. These sections include a description of the Priority Habitats polygons crossed by the New Bedford Main Line and Fall River Secondary and the suitable habitat for rare species within these areas. Because the Southern Triangle covers an extensive area and crosses several diverse habitats, existing conditions are described for individual segments along New Bedford Mainline and Fall River Secondary.

Table 4.15-4 Southern Triangle Priority and Estimated Habitats

Species	Priority Habitat (PH) (Identification #)	Estimated Habitat (EH) (Identification #)	Project Alternative (Areas of High Biodiversity)
Eastern Box Turtle (Terrapene carolina carolina) Mocha Emerald (Somatochlora linearis) Hessel's Hairstreak *(Callophrys hesseli)*	1093	951	New Bedford Main Line and Fall River Secondary (Assonet Cedar Swamp/Mass Audubon Great Cedar Swamp/Assonet River/Cedar Swamp River/ Cotley River)
Long-Leaved Panic-Grass (Panicum rigidulum ssp. pubescens) Data-sensitive species	1158	372	New Bedford Main Line (Apponquet Regional High School/Cedar Swamp River/ wooded swamp)
Eastern Box Turtle (Terrapene carolina carolina) Coastal Swamp Amphipod (*Synurella chamberlaini*) Pale Green Pinion Moth (*Lithophane viridipalle*) Water-Willow Stem Borer Moth (*Papaipema sulphurata*)	1349	1	New Bedford Main Line (Acushnet Cedar Swamp)

* Mapped habitat is within 100 feet of but does not intersect the right-of-way.

New Bedford Mainline

Assonet Cedar Swamp (PH 1093/EA 951) (New Bedford Main Line)—The polygon with Priority Habitat (PH1093) includes the Assonet Cedar Swamp which is located in Lakeville and is sometimes referred to as the Great Cedar Swamp. The Great Cedar Swamp borders the Cedar Swamp River and Assonet River south of Myricks Junction (Figure 4.15-5). The Assonet Cedar Swamp includes the Assonet Cedar Swamp Wildlife Sanctuary, a 1,000-acre parcel of conservation land in Lakeville owned by the Massachusetts Audubon Society (Figure 4.15-5). The existing New Bedford Main Line, currently used for freight rail service, crosses the Assonet Cedar Swamp for approximately 1 mile and forms its western boundary for approximately 1 mile in Lakeville. The extensive wetland contains one of the largest Atlantic white cedar swamps in the state.

This polygon extends for approximately 3.5 miles through Berkley and Lakeville. Because the polygon covers an extensive area and crosses several diverse habitats, existing conditions are described for individual segments within the polygon.

Northern Limit to Padelford Street—This section extends for 0.9 mile (Figure 4.15-4-5), and is an active freight railroad. The railbed was constructed for a double track, and currently contains a single track and a maintenance roadway. The railbed passes through forested uplands and two large wetlands associated with the Cotley River (BKCM 4, BKCM 11, BKCM 18). Portions of these wetlands are dominated by shrub swamp. The Cotley River passes under the railbed.

This segment is bordered by areas of suitable upland habitat for eastern box turtle. The open soils of the maintenance road, although dense and stony, may be used for nesting although they do not provide optimal habitat. The existing tracks are a barrier to the movement of eastern box turtles.

Padelford Street to Myricks Street—This section extends for 0.65 mile (Figure 4.15-5), and is an active freight railroad. The railbed was constructed for a double track, and currently contains a single track and a maintenance roadway. The railbed primarily passes through a large wetland which is forested on the west side of the right-of-way (BKCM 14) and a shrub swamp on the east side (BKCM 20).

This segment is bordered by areas of suitable upland habitat for eastern box turtle. The open soils of the maintenance road may be used for nesting although they do not provide optimal habitat due to the dense and stony substrate. The existing tracks are a barrier to the movement of eastern box turtles.

Myricks Street to Malbone Street—This section extends for 0.4 mile (Figure 4.15-5), and is an active freight railroad. The railbed was constructed for a double track, and currently contains a single track and a maintenance roadway. The railbed primarily passes through upland areas which are disturbed, and passes between two small forested wetlands (BK 1, BKN 1).

This segment is bordered by areas of marginally suitable upland habitat for eastern box turtle. The open soils of the maintenance road, although dense and stony, may be used for nesting although they do not provide optimal habitat. The existing tracks are a barrier to the movement of eastern box turtles.

Malbone Street to Southern Limit Assonet Cedar Swamp—This section extends for 1.7 miles (Figures 4.15-5), and is an active freight railroad. The railbed was constructed for a double track, and currently contains a single track and a maintenance roadway. The railbed is an elevated berm above wetlands for much of its length, passing through a complex of deciduous forested wetlands, Atlantic white cedar swamp, and more open shrub-dominated swamp. Two perennial streams (Pierce Brook and the Cedar Swamp River) cross under the railbed and may provide habitat for the mocha emerald (*Somatochlora*).

This segment is bordered by some areas of suitable upland habitat for eastern box turtle. The open soils of the maintenance road, although dense and stony, may be used for nesting although they do not provide optimal habitat. The existing tracks are a barrier to the movement of eastern box turtles. The adjacent wetlands also provide habitat for Hessel's hairstreak (in Atlantic white cedar trees) and the mocha emerald dragonfly may breed in adjacent streams.

Howland Road Area (PH 1158/EA 372)—This 0.5 mile polygon is an active freight railroad (Figure 4.15-5-6) located in Lakeville and Freetown. The railbed was constructed for a double track, and currently contains a single track and a maintenance roadway. The northern section is bordered primarily by forested upland, with a complex of smaller interconnected wetlands in the central portion (LK 12 to LK 19) includes open space areas such as the Apponquet Regional High School, wooded swamps, and other wetlands associated with the Cedar Swamp River. These are forested wetlands, although portions of LK 18 are mapped as Atlantic white cedar swamp (coniferous wetland). Several small culverts convey streams beneath the railbed.

This segment is bordered by areas of suitable upland habitat for eastern box turtle. The open soils of the maintenance road, although dense and stony, may be used for nesting although they do not provide optimal habitat. The existing tracks are a barrier to the movement of eastern box turtles. There are no open coastal plain pond or sandy wetland habitats adjacent to the railbed that provide suitable habitat for long-leaved panic-grass. Within the portion of the polygon (PH1158) crossed by the New Bedford Main Line, one data-sensitive species is also known to be present.[19]

[19] NHESP letter dated January 8, 2009.

Acushnet Cedar Swamp (PH 1349/EH 1)—The polygon with Priority Habitat (PH1349) includes the Acushnet Cedar Swamp State Reservation, which is an approximately 1,000-acre property located in New Bedford and Dartmouth, north of the New Bedford Airport (Figure4.15-7). This is one of eight cedar swamps in public ownership in Massachusetts, and has been designated by the U.S. Department of the Interior – National Park Service as a National Natural Landmark.[20] The existing New Bedford Main Line, currently used for freight rail service, forms the eastern boundary of the State Reservation for approximately 1.5 miles in New Bedford and crosses it for approximately 800 feet. It is an outstanding example of an Atlantic white cedar swamp and provides habitat for several state-listed species. Within the part of the Acushnet Cedar Swamp and adjacent areas crossed by the New Bedford Main Line, four state-listed species (eastern box turtle, coastal swamp amphipod, pale green pinion moth, and water-willow stem borer moth) are known to be present.[21]

This polygon extends for approximately 3 miles through Freetown and New Bedford. Because the polygon covers an extensive area and crosses several diverse habitats, existing conditions are described for individual segments within the polygon.

Northern Limit Acushnet Cedar Swamp to Chipaway Road—This 1,600-foot section (Figure 4.15-6) is an active freight railroad. The railbed was constructed for a double track, and currently contains a single track and a maintenance roadway. It is bordered by two narrow forested wetlands (FRN-25, FRN 26) and upland forest.

This segment is bordered by areas of suitable upland habitat for eastern box turtle. The open soils of the maintenance road, although dense and stony, may be used for nesting although they do not provide optimal habitat. The existing tracks are a barrier to the movement of eastern box turtles. Ditches and wetlands adjacent to the right-of-way may provide suitable habitat for the coastal swamp amphipod. Adjacent wetlands may also provide suitable habitat for the pale pinon moth and the water-willow stem borer moth.

Chipaway Road to Samuel Barnett Boulevard—This 1.2 mile section (Figure 4.15-7) is an active freight railroad. The railbed was constructed for a double track, and currently contains a single track and a maintenance roadway. The land to the east, in the northern portion of this section, is a commercial cranberry bog operation consisting of managed bogs and a large pond. The remaining section is bordered by upland forest and forested wetlands containing one certified vernal pool.

This segment is bordered by areas of suitable upland habitat for eastern box turtle. The open soils of the maintenance road, although dense and stony, may be used for nesting although they do not provide optimal habitat. The existing tracks are a barrier to the movement of eastern box turtles. Ditches and wetlands adjacent to the right-of-way may provide suitable habitat for the coastal swamp amphipod. Adjacent wetlands may also provide suitable habitat for the pale pinon moth and the water-willow stem borer moth.

Samuel Barnett Boulevard to Route 140—This 1.5 mile section (Figure 4.15-7-8) is an active freight railroad. The railbed was constructed for a double track, and currently contains a single track and a maintenance roadway. The land west of the right-of-way is the Acushnet Cedar Swamp State Reservation, and is predominantly forested wetland (NB 22). This wetland is primarily deciduous or

[20] Sorrie, Bruce A. and Henry L. Woolsey, 1987. The Status and Distribution of Atlantic White Cedar in Massachusetts. In A. Laderman, Atlantic White Cedar Wetlands, Westview Press. Pp. 135-142.

[21] NHESP letter dated January 8, 2009.

mixed wetland, with some areas dominated by Atlantic white cedar swamp. Although there is a narrow wetland along the east side of the right-of-way (NB 20), industrial and residential development are close to the railroad right-of-way along this entire segment.

This segment is bordered by areas of suitable upland habitat for eastern box turtle. The open soils of the maintenance road, although dense and stony, may be used for nesting although they do not provide optimal habitat. The existing tracks are a barrier to the movement of eastern box turtles (although it is unlikely that box turtles occur east of the right-of-way due to extensive development). Ditches and wetlands adjacent to the right-of-way may provide suitable habitat for the coastal swamp amphipod. Adjacent wetlands may also provide suitable habitat for the pale pinon moth and the water-willow stem borer moth.

A transfer power substation is proposed in this segment, immediately south of the powerline right-of-way that parallels Samuel Barnet Boulevard. This would result in the loss of 1.25 acres of potential eastern box turtle habitat.

Fall River Secondary

Within the part of the Assonet Cedar Swamp and adjacent areas crossed by the New Bedford Main Line and Fall River Secondary, three state-listed species (eastern box turtle, mocha emerald, and Hessel's hairstreak) are known to be present.[22] The Fall River Secondary passes through this Priority Habitat (PH1093) from Myricks Junction to Beechwood Road (1.1 miles) (Figures 4.15-9-11). This active freight railroad was constructed as a single track. In the northern section, the railbed is bordered by disturbed uplands or lawns. The remaining section is bordered by forested uplands or forested wetlands (deciduous). The railroad crosses the Cedar Swamp River on a bridge. The Cedar Swamp River may provide suitable habitat for the mocha emerald. There are no Atlantic white cedar swamp habitats along this section.

One culvert in this segment that would be reconstructed to meet Commonwealth of Massachusetts Stream Crossing Standards,[23] and the Cedar Swamp River bridge would be reconstructed with wildlife shelves. None of the filled wetland provides suitable habitat for the mocha emerald. Improving culverts and bridges within this segment could have temporary construction-period impacts to mocha emerald habitat, but would result in an overall improvement by replacing culverts with open-bottom structures.

Potential Rare Species Habitat

This section summarizes the potential rare species habitat adjacent to the right-of-way. Both the New Bedford Main Line and Fall River Secondary are active freight lines with ballasted right-of-way, tracks and ties. There are culverts that convey streams underneath the embankment. The right-of-way itself does not provide suitable habitat for any of the rare species and the tracks and ties prevent turtles and amphibians from moving across the right-of-way, except through the culverts.

- Suitable forested upland habitat for the eastern box turtle is found boarding the New Bedford Main (Acushnet Cedar Swamp and Assonet Cedar Swamp).

[22] NHESP letter dated January 8, 2009.

[23] River and Stream Crossing Partnership. 2011. Massachusetts River and Stream Crossing Standards. The University of Massachusetts- Amherst (College of Natural Sciences), The Nature Conservancy, Massachusetts Division of Ecological Restoration- Riverways Program, American Rivers, and others. August 2004; revised March 1, 2006; revised March 1, 2011; corrected January 31, 2012.

- Coastal swamp amphipods may find suitable habitat within slow-moving streams and inundated hollows in the forested swamps of Acushnet Cedar Swamp.

- Mocha emerald may find suitable habitat along streams that flow through woods or swamps of the Assonet Cedar Swamp.

- Pale green pinion moth may find suitable habitat within wooded swamps of the Acushnet Cedar Swamp.

- Water-willow stem borer moth is a globally restricted species, occurring only in southeastern Massachusetts along upland edges of streams and ponds where its obligate host, water-willow, occurs. It may find suitable habitat in seasonally flooded swamps and along edges of streams and ponds.

- Hessel's hairstreak may find suitable habitat in the Atlantic white cedars that have become established on the sideslopes of the embankment within the Assonet Cedar Swamp and the extensive areas of Atlantic white cedar swamp within these wetlands.

- Long-leaved panic-grass likely does not find suitable habitat within portions of the Priority Habitat (PH1158) adjacent to the New Bedford Main Line because there are no coastal plain ponds located adjacent to the railroad embankment. NHESP has recently determined that habitat of two additional species, wood turtle and ringed boghaunter dragonfly occurs near the Southern Triangle. Due to its location in relation to the proposed railway alignment an analysis of impacts to these two state-listed species was not included in this chapter.

Eastern box turtles may find some suitable habitat within the forested, shrub or meadow portions of the mapped Priority Habitats (PH261 and PH1439) associated with the Three Mile River.

Stoughton Alternative

The study area for the Stoughton Alternative, north of Weir Junction, includes improvements to existing active freight or rail lines (from north of Stoughton Station, and Dean Street to Cotley Junction) and track construction on out-of-service or abandoned rights-of-way (between Stoughton Station and Dean. This Alternative would include constructing a trestle through part of the Hockomock Swamp to reduce impacts to wetlands and rare species.

Based on the 2008 NHESP Atlas, the Stoughton Alternative crosses two Priority and Estimated Habitats (PH1392/EH59, and PH1297/EH1077). These Priority habitats include land within the Hockomock Swamp ACEC, and Pine Swamp (Figures 4.15-12-15).

Table 4.15-5 lists the species found adjacent to the Stoughton Alternative corridor within these Priority and Estimated Habitats, based on information provided by NHESP.

Table 4.15-5 Stoughton Alternative Study Area—Priority and Estimated Habitats

Species	Priority Habitat (PH) (Identification #)	Estimated Habitat (EH) (Identification #)	Project Alternative (Areas of High Biodiversity)
Blue-Spotted Salamander (*Ambystoma laterale*) Blanding's Turtle (*Emydoidea blandingii*) Eastern Box Turtle (*Terrapene carolina carolina*) Gypsywort (*Lycopus rubellus*)	1392[1]	59	Stoughton Alternative (Hockomock Swamp ACEC/Hockomock Swamp WMA)
Hessel's Hairstreak *(Callophrys hesseli)*	1297	1077	Stoughton Alternative (Pine Swamp)

1 Priority Habitat (PH1392) includes an additional 11 state-listed species which do not occur adjacent to the rail corridor.

These sections include a description of the Priority Habitat polygons crossed by the Stoughton Alternative and the suitable habitat for rare species within these areas.

Hockomock Swamp ACEC (PH1392)—This polygon extends for a total of 5.5 miles from Purchase Street in Easton to I-495 in Raynham. The polygon with Priority Habitat (PH1392) includes the Hockomock Swamp ACEC, which is approximately 16,950 acres of land in Bridgewater, Easton, Norton, Raynham, Taunton, and West Bridgewater (Figures 4.15-14-15). The ACEC is fragmented by several major transportation corridors, including Routes 24, I-495, 138, 106, and other major roadways, and it includes substantial upland areas within the watershed of the Hockomock Swamp. These uplands include land developed in commercial and residential uses as well as undeveloped forested upland and farmland.

The DCR describes the ACEC as one of the most extensive inland wildlife habitats in southeastern Massachusetts. The Atlantic white cedar swamp and acidic fen wetland communities scattered throughout the Hockomock Swamp ACEC are considered to be outstanding examples of these unique natural communities. The ACEC provides habitat for at least 13 species listed as rare, endangered, or of special concern by the NHESP, and much of the ACEC is designated as BioMap Core Habitat. Within the part of the ACEC crossed by the Stoughton Alternative, four state-listed species (blue-spotted salamander, Blanding's turtle, eastern box turtle, and gypsywort) are known to be present.[24] The majority of the vernal pools that support blue spotted salamanders are located between Foundry Street and the existing power line, near the South Easton Vocational and Technical School. The Atlantic white cedar stands also provide potential habitat for Hessel's hairstreak. Because the polygon covers an extensive area and crosses several diverse habitats, existing conditions are described for individual segments within the polygon. However, Atlantic white cedar trees are confined to the west side of the existing railroad grade, evidencing the probability that the original establishment of the right-of-way in ca. 1866 eventually altered the delicate hydrogeology of the previously contiguous Atlantic white cedar swamp.

Purchase Street to Prospect Street—The railroad right-of-way within this 0.75 mile section (Figure 4.15-14) consists of a narrow (6 feet wide) gravel pathway on the former railbed. There are drainage ditches on either side of the railbed that have become partially blocked. Due to these blockages, drainage has been diverted onto the railbed, which functions as an intermittent stream. Residences are immediately

[24] NHESP letter dated January 8, 2009.

adjacent to the railbed on the west side, for approximately 0.4 mile. The adjacent land is primarily forested, and includes forested uplands and wetlands.

This segment is bordered by areas of suitable upland habitat for eastern box turtle. Eastern box turtles, if present, may move across the right-of-way to access suitable habitat areas on either side. NHESP also considers this segment to be within the potential habitat of Blanding's turtle.

Prospect Street to Foundry Street—The railroad right-of-way within this 0.9 mile section (Figure 4.15-14) consists of a 10-foot wide gravel pathway on the former railbed (with evidence of use by ATVs). For the northern 0.3 mile, the right-of-way is bordered by forested upland and wetland on the west, associated with Black Brook, and by a golf course on the east. For the next 0.3 mile, the right-of-way passes between two golf courses. The southern third passes between two large wetlands (EA 82, EA 81). A certified vernal pool is east of the right-of-way just north of Foundry Street. During the 2001 field study, a single blue-spotted salamander was trapped in this area.

This segment is bordered by areas of suitable upland habitat for eastern box turtle and wetlands potentially used by Blanding's turtle. Sandy soils in the golf courses may provide nesting habitat for either turtle species, which, if present, may move across the right-of-way to access suitable habitat areas on either side.

Foundry Street to Power Line—The railroad right-of-way within this 0.6 mile section (Figure 4.15-14) consists of a wide gravel pathway on the former railbed (with evidence of use by ATVs). The Southeast Regional Vocational Technical High School is east of the right-of-way at Foundry Street. The baseball field is immediately adjacent to the railbed. The right-of-way passes through a white pine forested upland and deciduous forested upland and wetlands (EA 77, EA 78) in the northern half and deciduous forested wetland (EA 63, EA 64) in the southern half. An open former sand/gravel pit is west of the railbed at Wetland EA 65.1. Several certified vernal pools are within this section, on both sides of the railbed. At the southern end of this section, the railbed crosses a right-of-way for an overhead power line and the powerline maintenance road. The railbed consists of an open, wide sandy road adjacent to wetlands dominated by woody shrubs, including of highbush blueberry, sweet pepperbush, swamp azalea, and common winterberry (*Ilex verticillata*). Typical herbaceous vegetation include skunk cabbage (*Symplocarpus feotidus)*, cinnamon fern (*Osmunda cinnamomea*), and sensitive fern (*Onoclea sensibilis*) and in some disturbed areas giant reed grass (*Phragmites australis*).

This segment is bordered by areas of suitable upland habitat for eastern box turtle, wetlands potentially used by Blanding's turtle, and vernal pools used as breeding habitat by blue-spotted salamanders. Sandy soils in the gravel pit, or in the ballfield, may provide nesting habitat for either turtle species. All three species may move across the right-of-way to access suitable habitat areas on either side. Significant use of the ACEC by ATVs is evident along the right-of-way, within the abandoned gravel pit, and within side trails, many of which pass in serpentine or circuitous pathways across and through the vernal pools, causing significant disturbance to the soils and likely concomitant damage to egg masses and larval and juvenile stages of amphibians, particularly blue spotted salamander, American toad (*Bufo americanus*) and wood frogs (*Rana sylvatica*). These uses are neither sanctioned nor actively prohibited by MassDOT or Department of Fish and Game personnel.

The northernmost 1,200 feet of this segment would be the approach to the trestle. In this approach segment, the track would slope up, and retaining walls would be used to minimize fill. A traction power substation would be constructed east of the right-of-way, within an area of white pine forest or in the

ballfield. The track would be on the trestle for majority of this section, and the only impacts would result from vegetation removal.

Power Line to Former Raynham Greyhound Park—The railroad right-of-way within this 1.7 mile section (Figures 4.15-14-15) consists of a wide gravel pathway on the elevated former railbed (with evidence of use by ATVs). The railbed passes through primarily forested red maple-dominated wetlands, although there is an open emergent marsh and shrub swamp west of the railbed (south of the powerline), a large vernal pool east of the railbed, (probably a former borrow pit from which earthen materials were once extracted to construct the grade), and an Atlantic white cedar swamp located entirely west of the railbed and extending for approximately 0.6 mile north of the former Raynham Greyhound Park. Three certified and two potential vernal pools occur within this section.

This segment is bordered by wetlands potentially used by Blanding's turtle, wetlands and uplands potentially used by eastern box turtles, and vernal pools used as breeding habitat by blue-spotted salamanders. Based on prior studies, the railroad embankment through the Hockomock Swamp provides limited nesting habitat due to the dense gravel substrate and shaded light regime. Although turtles are occasionally observed to nest on the embankment, the open sandy soils under the power line and along the power line roadway are preferred nesting sites based on field observations by the Corps and others of nesting turtles and predated nests. Sandy soils under the powerline may provide nesting habitat for either turtle species. All three species may move across the right-of-way to access suitable habitat areas on either side. Gypsywort occurs in the open emergent wetland west of the railbed, south of the power line. There would be no impact to this population.

Former Raynham Greyhound Park to Bridge Street—The railroad right-of-way within this 1.1 mile section (Figure 4.15-15) consists of a wide gravel roadway on the former railbed, with evidence of extensive use by ATVs. The northernmost 1,400 feet of this section is bordered to the east by an industrial park, with a detention basin that drains onto the right-of-way. This drainage, combined with a stream flowing from the west, has been identified as a perennial stream flowing north within the railbed. The railbed passes through primarily upland forest, and passes through one small wetland system (R 61, R 59). A maintained powerline is located on the east side of the railbed. A complex of potential vernal pools occurs on both sides of the railbed approximately 1,500 feet north of Bridge Street.

This segment is bordered by areas of suitable upland habitat for eastern box turtle. Eastern box turtles, if present, may move across the right-of-way to access suitable habitat areas on either side.

Bridge Street to I-495—The railroad right-of-way within this 0.25 mile section consists of a wide gravel path on the former railbed. The railbed is bordered by a small park and ballfield to the east, and by residential development on both sides. Elm Street crosses the right-of-way mid-way between Bridge Street and the highway.

Pine Swamp (PH1298)—The polygon with Priority Habitat (PH1297) includes the Pine Swamp, a 275-acre wetland system in western Raynham that includes several properties owned by the Town of Raynham Conservation Commission (Figures 4.15-15). This area consists of forested and marsh wetlands and is located within mapped estimated habitat of several rare wetlands species. It supports an Atlantic

white cedar swamp community. Within the part of the Pine Swamp crossed by the Stoughton Line, one state-listed species (Hessel's hairstreak) is known to be present.[25]

The railroad right-of-way through Pine Swamp, between King Phillip Street and East Britannia Street (Figure 4.15-15), is on an elevated berm for the northern 0.5-mile section and at-grade in the southern section. The railbed contains a narrow (3 to 4 feet wide) path and a powerline owned by the Taunton Municipal Light Company. The northernmost 500 feet is bordered by residential development on the west side. An auto junkyard is east of the right-of-way at the East Britannia Street crossing. The railbed and adjacent powerline are predominantly vegetated with shrubs and herbaceous species, including giant reed grass. Adjacent areas are forested or shrub-dominated wetlands (including a large stand of giant reed grass). The forested wetland east of the railbed is dominated by deciduous trees, while the forested wetland west of the railbed is dominated by Atlantic white cedar.

Atlantic white cedar trees, present in the wetland west of the railbed and on the railbed itself, provide breeding habitat for Hessel’s hairstreak butterflies. Atlantic white cedars are present at low densities in Wetland RA12.2, west of the railbed, between the southern Pine Swamp Brook crossing and the northern Pine Swamp Brook crossing. The southernmost trees are located at wetland flag RA12.2-154 (STA 1729), and are approximately 6 feet west of the wetland flag. The northernmost trees are located at wetland flag RA12.2-138 (STA 1711). The Atlantic white cedar community spans a distance of approximately 1,800 linear feet. Trees are primarily growing on the west side of the perimeter ditch, 5 to 6 feet west of the wetland flags. There are occasional trees on the railbed side of the ditch. The Atlantic white cedars occur at low densities within a predominantly red maple (*Acer rubrum*) forested wetland, and co-occur with tupelo (*Nyssa sylvatica*), white pine (*Pinus strobus*), highbush blueberry, dangleberry (*Gaylussacia frondosa*), sweet pepperbush, and poison sumac (*Toxicodendron vernix*). A total of 35 trees were observed on, or within 10 feet of the railbed along this 1,800 foot distance.

Potential Rare Species Habitat

This section summarizes the potential rare species habitat adjacent to the right-of-way. The Stoughton Line is an inactive line without tracks and ties for most of its length. There are culverts that convey streams underneath the embankment. In addition to the culverts, the right-of-way itself provides suitable migratory habitat for rare species in locations where there are no tracks and ties to prevent turtles and amphibians from moving across the right-of-way. The right-of-way may provide suitable nesting, feeding, sheltering, or overwintering habitat for rare species where it has become overgrown. However, portions of the right-of-way show evidence of heavy although unauthorized use by all-terrain vehicles (ATVs), pedestrians and bicycles. Several existing vernal pools adjacent to or nearby the right-of-way also exhibit use by ATVs, with obvious pathways of tire-ruts leading from the railroad corridor into the adjacent habitats, and disturbed soil throughout. This has obvious negative consequences for habitat by crushing eggs or other sensitive life stages of rare species and/or their preferred prey. Nevertheless, successful migrations across the right-of-way by blue-spotted salamanders and certain other fauna are likely not jeopardized by these uses of the corridor, since such crossings generally occur at night and/or early spring when ATVs and other users of the track are likely to be less prevalent. More severe impacts from ATVs are likely within the vernal pools themselves.

As described in Section 4.15.2, a study was conducted in the spring and summer of 2001 to determine rare species occurrences in the Hockomock and Pine Swamps. The study documented a substantial population of blue-spotted salamanders that crossed the right-of-way in both directions. No blue-

[25] Ibid.

spotted salamanders were found in Pine Swamp or in the Hockomock ACEC south of the former Greyhound Park. The largest concentration (85 percent of all animals) was found between the powerline corridor and the Greyhound Park. The Stoughton Line provides migratory habitat for the blue-spotted salamanders.

Based on the Blanding's turtle survey conducted in 2008 within the Hockomock Swamp, Blanding's turtles may find suitable aquatic habitat primarily associated with Black Brook (where it crosses the right-of-way) as well as within vernal pools and other isolated pockets within the greater Hockomock Swamp area. The utility corridor that crosses the rail right-of-way provides suitable nesting habitat for the turtles. Nesting habitat provided within or adjacent to the rail right-of-way is of marginal quality in those areas where the canopy is open enough to allow sunlight to incubate the eggs for long enough periods of time for viable survival.

The eastern box turtle may find some suitable habitat within the forested portions of the right-of-way. However, due to its linear nature and lack of adjacent expanses of forested uplands, it is not ideal habitat for this species. Eastern box turtles are more likely to be found within the upland portions of the powerline corridor and the forested upland areas within the study area. During the 2001 rare species survey, one eastern box turtle was captured and fitted with a radio transmitter. This turtle (designated B1) was captured in the upland forest west of the right-of-way, north of Bridge Street in Raynham. The 2001 rare species study determined that eastern box turtles are infrequently found within the Hockomock Swamp ACEC, and that this species was found to occur only within upland forested areas south of the former Greyhound Park. The 2008 Blanding's turtle study conducted in the Hockomock Swamp (south of Foundry Street) found no eastern box turtles during the nest surveys.

The project corridor may provide marginal nesting habitat for eastern box turtles. However, these areas would be limited to portions of the right-of-way where the canopy is open enough to allow sunlight to incubate the eggs for long enough periods of time for viable survival. Turtles moving between patches of suitable habitat may also cross the right-of-way.

During the 2001 rare species studies, suitable habitat for Hessel's hairstreak was observed where Atlantic white cedars have become established on the sideslopes of the embankment within Hockomock Swamp and Pine Swamp as well as the extensive areas of Atlantic white cedar swamp within these wetlands. No Hessel's hairstreaks were observed during this study.

During the 2001 rare species study, suitable habitat for water-willow stem borer was observed within the Hockomock Swamp in two areas where water-willows were identified along the Stoughton Alternative. One small population of gypsywort was identified within 10 to 15 feet of the railroad berm south of the utility corridor. It is likely that additional areas of suitable habitat exist within the Hockomock Swamp.

Whittenton Alternative

The Whittenton Alternative runs predominantly along the same route as the Stoughton Alternative. The Whittenton Alternative is different from the Stoughton Alternative only along a portion of right-of-way between Raynham Junction and Weir Junction, a length of approximately 5.8 miles. A section of the Whittenton Alternative, known as the Whittenton Branch, diverges from the Stoughton Line at Raynham Junction and travels through Raynham and Taunton for approximately 3.4 miles to Whittenton Junction. This section of track is inactive. At Whittenton Junction, the track joins the Attleboro Secondary, an active rail line, for approximately 2.4 miles to Weir Junction at the beginning of the New Bedford Main

Line. The Whittenton and Stoughton Alternatives run the same route on the Stoughton Line from Canton to Raynham Junction. The New Bedford Main Line and the Fall River Secondary are also identical for both alternatives. Figure 4.15-16-17 shows the Whittenton Alternative.

Priority Habitat polygons (PH261 and PH1439) include portions of the recently-designated Three Mile River Watershed ACEC. This ACEC covers approximately 14,275 acres in Dighton, Norton, and Taunton (Figures 4.15-16-17). The ACEC is fragmented by Route 140, a major transportation corridor, and several other major roadways. It includes substantial upland areas that are developed with commercial and residential uses as well as undeveloped forested upland and farmland.

The ACEC provides habitat for several species listed by the NHESP as rare, endangered, or of special concern. Within the part of the ACEC crossed by Whittenton Alternative on the Attleboro Secondary, one state-listed species (eastern box turtle) is known to be present. The Three Mile Watershed contains many important habitats. A total of 13,486 acres (nearly 95 percent) of the ACEC are comprised of the habitats designated by the NHESP as BioMap Core Habitat and Supporting Natural Landscapes, and as Living Waters Core Habitat and Critical Supporting Watersheds. The certified vernal pools in the ACEC have been found to provide breeding habitat for wood frogs, spotted salamanders (*Ambystoma maculatum*), and fairy shrimp (*Eubranchipus* spp.). The inland wetlands provide food, cover, and shelter for waterfowl, muskrats (*Ondatra zibethica*), snakes, turtles, amphibians, and insects. The floodplain provides essential breeding habitat for reptile and amphibian species, including several NHESP listed species.

Potential Rare Species Habitat

A portion of the Whittenton Branch and a portion of the Attleboro Secondary are within an area listed by the NHESP as eastern box turtle habitat. This area extends from Warren Street on the Whittenton Branch to Whittenton Junction, and along the Attleboro Secondary to a point approximately 500 feet before Danforth Street. The right-of-way itself does not provide suitable habitat for any of the rare species, and the tracks and ties constrain the movement of turtles and amphibians across the right-of-way except through the culverts.

Impacts to rare species habitat are not expected along the Attleboro Secondary because it is an existing active rail line and already presents a barrier to wildlife movement.

Along the Whittenton Branch, while the existing access road does not constitute wildlife habitat, constructing the railroad would result in additional impacts on either side of this road. More substantial impacts would occur along the southernmost section of the right-of-way between the access road and Whittenton Junction, where the path is narrower. Area of impact was estimated by measuring the area inside the limit of work (limit of grading) and subtracting the area of the roadway and path, based on available survey information. A total of approximately 1.2 acres of rare species habitat (successional vegetation along the edge of the traveled path) would be permanently impacted from constructing the railroad. In addition, a total of approximately 0.6 additional acre of eastern box turtle habitat would be temporarily impacted, based on an estimated additional 4 feet outside the limit of grading on both sides of the right-of-way that would be necessary to construct the berm and grading for the railroad. All impacted habitat is upland area except for approximately 460 square feet of permanent impact and 820 square feet of temporary impact to Wetland RWB 04. Wildlife crossings are proposed to facilitate movement under the right-of-way, as described in the previous section

Stations

This section describes the Priority and Estimated Habitats within the proposed station sites associated for the Stoughton and Whittenton Alternatives.

None of the proposed station sites are within mapped Priority Habitat. All the proposed station sites are within partially or fully developed areas. Raynham Park is the only station where the platform would be within mapped Priority Habitat (PH1392); the rest of the Raynham Park station site and its parking lot would not be within the Priority Habitat polygon. This station would serve the Stoughton Alternative and is located at the former Greyhound Park in Raynham (Figure 4.15-15). The Raynham Park Station site is entirely developed and does not provide potential habitat. Based on the habitat requirements of the species known to occur in the study area, it is unlikely that any of the identified rare species would be found on any of the station sites, except for the Eastern Box Turtle, which is a habitat generalist.

Layover Facilities

Neither of the proposed overnight layover facilities (Wamsutta and Weaver's Cove East) are located within a Priority or Estimated Habitat polygon.

One midday rail layover facility is planned for the Boston area, This site is associated with the proposed expansion of South Station, which has independent utility of the South Coast Rail project and is not part of the South Coast Rail project. Any impacts associated with the expansion of South Station, including midday layover facilities, would be addressed through the environmental review process associated with the proposed expansion of South Station. The proposed expansion of South Station is discussed in Chapter 3 as part of the No-Build Alternative.

4.15.2.5 Summary of Existing Conditions

A total of 9 state-listed rare species, have been recorded in areas adjacent to the alternatives corridors. These include one salamander, two turtles, one crustacean, three moths and butterflies, one dragonfly, and one plant species.

The Southern Triangle, common to all Build Alternatives, includes two active freight lines with ballasted right-of-way, tracks and ties. The right-of-way does not provide suitable habitat for any of the rare species, and the tracks and ties prevent turtles and amphibians from moving across the right-of-way except through the culverts. Suitable foraging, breeding, and nesting habitat for rare species occurs adjacent to the rail rights-of-way, particularly in the Assonet Cedar Swamp and Acushnet Cedar Swamp.

The Stoughton Alternative is an inactive right-of-way corridor without tracks and ties from Easton (Short Street) to Longmeadow Street in Taunton . Along this corridor, the right-of-way itself may provide migratory habitat for rare species such as the blue-spotted salamander, Blanding's turtle, and eastern box turtle because there are no tracks and ties to prevent small animals from moving across the right-of-way. The right-of-way itself is unlikely to provide suitable nesting, breeding, or foraging habitat for rare species. Areas on and adjacent to the right-of-way provide habitat for state-listed plants and invertebrates.

The Whittenton Branch and a portion of the Attleboro Secondary are within an area listed by the NHESP as eastern box turtle habitat. The right-of-way itself does not provide suitable habitat for any of the rare species, and the tracks and ties constrain the movement of turtles and amphibians across the right-of-way except through the culverts.

None of the proposed station sites intersect mapped areas of Priority and Estimated Habitat. The only station site that is located adjacent to mapped areas of Priority Habitat is Raynham Park), which largely developed and does not contain significant habitat resources. Based on the habitat requirements of the species known to occur in the study area, it is unlikely that rare species would be found at the proposed station platform site. The eastern box turtle is a habitat generalist and could occur at undeveloped station sites such as the Taunton Depot Station sites, although none have been observed at that location. Table 4.15-6 provides a summary of existing conditions and compares the different alternatives.

Table 4.15-6 Summary of Project Alternatives near Suitable Rare Species Habitat

Alternative	Total # of PH and EH Intersected / Adjacent	Total # of Rare Species Recorded
Southern Triangle New Bedford Main Line	3	7
Fall River Secondary	3	7
Stoughton Alternative Stoughton Alignment	2	5
Whittenton Alternative Whittenton Alignment	3	5

4.15.3 **Analysis of Impacts and Mitigation**

4.15.3.1 Introduction

This section describes and evaluates impacts that the proposed South Coast Rail alternatives may have on threatened and endangered species within the project study area. Both direct and indirect effects are considered and discussed for each of the project elements. Measures incorporated in the alternatives' designs to avoid and minimize, and when necessary mitigate for unavoidable impacts are described for each of the project elements. Regulatory jurisdiction and compliance with state, and federal regulations are also discussed.

This section also addresses the requirements of the Certificate of the Secretary of Environmental Affairs on the ENF dated April 3, 2009,[26] as well as the Secretary's Certificate on the DEIS/DEIR (June 29, 2011[27]), which required the following.

- Include a detailed quantification and analysis of the relative impacts of the alternatives on state-listed species and their habitats; the analysis should include all components of the project alternatives, including the rail alignments (including the Southern Triangle), stations and layover facilities, and secondary growth impacts.
- Describe how potential impacts of the alternatives will be avoided and minimized.
- Include a detailed description of proposed mitigation measures for each alternative.

[26] The Commonwealth of Massachusetts Executive Office of Energy and Environmental Affairs, Certificate of the Secretary of Energy and Environmental Affairs on the DEIS/DEIR, South Coast Rail Project (EEA# 14346), April 3, 2009.

[27] The Commonwealth of Massachusetts Executive Office of Energy and Environmental Affairs, Certificate of the Secretary of Energy and Environmental Affairs on the DEIS/DEIR, South Coast Rail Project (EEA# 14346), June 29, 2011.

- Describe the endangered species permitting process for each alternative based on consultations with NHESP.
- Discuss how costs associated with permitting, including mitigation requirements, are incorporated in the alternatives analysis.
- Consult with NHESP about the methodology to be used prior to any additional habitat analysis and to discuss metrics to be used in the FEIR for assessing impacts to state-listed species and their habitat.
- Consult with NHESP regarding the assumptions related to vegetation cover that were used in the DEIS/DEIR. The analysis of impacts for the Stoughton route should be revised in the FEIR to reflect the full range of vegetation cover types that each state-listed species requires, as recommended by NHESP.
- Quantify impacts to state-listed species, vernal pool habitat, general wildlife, and state-owned open space, and a detailed plan for minimization and mitigation of impacts.
- Provide comprehensive description of how the applicant proposes to meet MESA regulatory requirements, including the standards for authorizing a take of a state-listed species through a Conservation and Management Permit.
- Provide detailed descriptions and discussion of rare species and wildlife crossings and barrier design (for example, culverts and bridges) as well as other minimization measures such as construction management to minimize turtle and salamander mortality.
- Explain in detail how the project will meet the long-term “net benefit” standard in 321 CMR 10.23 including detailed mitigation plans that should be developed in consultation with NHESP. These mitigation plans should be at a very specific level of detail to demonstrate clearly that appropriate and effective mitigation will be implemented.
- Evaluate any potential impacts to migration associated with widening the existing tracks and right-of-way.

Section 4.15.3.2 describes the methodology and definition of impact, Section 4.15.3.3 identifies individual elements impacts along each alternative, Section 4.15.3.4 identifies general temporary construction period impacts, Section 4.15.3.5 summarizes the impacts by alternative, Section 4.15.3.6 presents mitigation approaches, and Section 4.15.4 describes compliance with state and federal regulatory requirements.

4.15.3.2 Impact Assessment Methodology

The proposed South Coast Rail alternatives and associated stations are expected to have direct and indirect effects on rare species and their habitat. This section discusses direct and indirect effects in general, and describes the methodology used to calculate and evaluate impacts to rare species within the project study area.

The list of state-listed species found within Priority and Estimated Habitat polygons that intersect or are adjacent to the project corridors was provided by the NHESP on January, 8, 2009, in response to a

formal request for a detailed list of species found within these Estimated and Priority Habitats. This chapter also addresses the requirements of the Certificate of the Secretary of Environmental Affairs on the ENF and DEIR/DEIS dated April 3, 2009,[28] and June 29, 2011,[29] respectively.

Method for Assessing Direct Impacts

Temporary and permanent direct impacts to rare species and their habitat are anticipated along each of the Build Alternatives. Direct impacts include impacts from construction, grading, vegetation management, and mortality associated with potential collisions with rail traffic. These activities may result in degradation of ecological function and, loss of habitat, as well as loss of rare plant and animal species. Potential temporary construction related impacts are described in Section 4.15.3.4. Permanent effects may include losses or changes in habitat and rare plant and wildlife species through clearing, grading, construction, and the potential introduction of undesirable, invasive species.

Potential habitat loss is a direct effect of transportation projects. Habitat loss occurs if an area that previously provided food, cover, water, and/or breeding resources to a rare species is cleared, paved, filled or altered in such a way that it no longer provides one or more of these resources.

The majority of the work associated with the Build Alternatives falls within existing railroad rights-of-way, therefore, minor temporary and permanent impacts to rare species habitat may occur within narrow strips immediately adjacent to the right-of-way as necessary for track reconstruction and minor re-alignment of track in certain areas.

Direct impacts were calculated through the use of a Geographic Information Systems (GIS) model. This model quantified impacts by intersecting proposed work areas with NHESP Priority and Estimated Habitat polygons for rare species. The model quantified all loss of habitat along the project corridors and at the proposed station sites based on the limit of permanent alteration. Areas within permanent alteration limits that are already disturbed, such as ballasted railbed and roads, were not counted as habitat loss. In addition, impact areas less than 10 feet wide were not counted as habitat loss, because impacts in those areas are expected to be avoided as the final design is developed. Impacts to wetland habitats were calculated based on the updated wetland delineations conducted for the project (and reviewed by each Conservation Commission pursuant to an Order of Resource Area Delineation) and the updated track designs. Temporary wetland impacts during construction were calculated based on an average 4-foot construction offset from the toe of slope. The cover type data were produced based on field observations and review of aerial photographs and MassGIS mapping, as well as field studies undertaken in 2001 and 2009. Additional field observations were made in 2011 during field review of the Abbreviated Notices of Resource Area Delineation filed with each of the corridor conservation commissions, and supplemented by additional field investigations to map specific habitat types in 2012.

Method for Assessing Indirect Impacts

The CEQ defines indirect effects (or impacts) as effects which are caused by the action and are later in time or farther removed in distance, but are still reasonably foreseeable. Indirect effects may include growth inducing effects and other effects related to induced changes in the pattern of land use, population density or growth rate, and related effects on air and water and other natural systems,

[28] The Commonwealth of Massachusetts Executive Office of Energy and Environmental Affairs, Certificate of the Secretary of Energy and Environmental Affairs on the DEIS/DEIR, South Coast Rail Project (EEA# 14346), April 3, 2009.

[29] The Commonwealth of Massachusetts Executive Office of Energy and Environmental Affairs, Certificate of the Secretary of Energy and Environmental Affairs on the DEIS/DEIR, South Coast Rail Project (EEA# 14346), June 29, 2011.

including ecosystems. Indirect effects change the quality or functions of a resource, are measured qualitatively and, therefore, are more difficult to accurately assess than direct effects. Indirect effects include habitat fragmentation and associated edge effects; the loss of genetic diversity of rare plant and animal populations, increased competition for resources, and physical or psychological restrictions on movements caused by some feature within a corridor that wildlife are unwilling or unable to cross. Indirect effects can be caused by the increased noise and visual disturbance from land-clearing, earth-moving, and construction machinery during construction. Following construction, noise associated with the active rail line may cause indirect effects if wildlife avoid habitat near the embankment.

Fragmentation is defined as the subdivision of once large and continuous tracts of habitat into smaller patches. It results from agriculture, urbanization, and transportation or other rights-of-way.[30] Fragmentation clearly has consequences on wildlife communities, especially on rare species. Habitat fragmentation is associated with edge effects when there is a disturbed or developed area created adjacent to a natural and/or forested area. Edge effects may include the spread of invasive species, increase in the canopy gap, and a decrease in species dependent on core and/or undisturbed habitat. In general, fragmentation of habitat is viewed as detrimental when considering original native, climax species composition and abundance, natural history, and relative ecological stability of unmanaged plant and animal populations.

A railroad corridor may act as a barrier that interferes with the movement of some mammals, amphibians, birds and reptiles from one habitat to another. The width of a railroad corridor can influence the frequency of wildlife crossings, as well as the mortality associated with potential collisions with rail traffic. The rail itself can create a barrier to smaller species such as amphibians, reptiles, and smaller mammals. Traffic density and traffic speed may also influence wildlife avoidance of transportation corridors.[31,32,33,34] The loss of migratory routes (barrier effect) was estimated by calculating the length of the new track through the polygons of Priority and Estimated Habitat. This is a conservative estimate of impact because it is unlikely that the entire length of the proposed new track would cross habitat suitable for migration.

For the purposes of calculating barrier effect impacts, it was assumed that impacts to migration would only occur on proposed new tracks. For the Stoughton Alternative and Whittenton Alternatives it would include new track construction on abandoned/out-of-service right-of-way segments of the former Stoughton Line and Whittenton Branch. Existing abandoned tracks such as those on portions of the abandoned Stoughton line provide a semi-porous access for wildlife due to missing cross-ties, missing lengths of rail, and other track degradation. Construction of new tracks in abandoned rail right-of-way would reduce the porosity typical of abandoned tracks and as such could impact migration. It was assumed that there would be no new impacts to migration in areas with existing active tracks.

4.15.3.3 Impacts of Alternatives by Element

This section describes specific potential impacts that the proposed South Coast Rail alternatives, stations, layover facilities, and traction power stations (specific to the electric alternatives) may have on rare species. These alternatives include the No-Build Alternative (Enhanced Bus), Stoughton Alternative (Electric and Diesel), and Whittenton Alternative (Electric and Diesel) (Figure 4.15-4 through 4.15-17).

The majority of the Build Alternatives use existing segments of active freight and commuter rail lines with ballasted right-of-way, tracks, and ties. Existing culverts carry streams beneath the railroad embankment. These culverts maintain wetland hydrology and provide crossing points for migratory wildlife to access wetland areas on either side of the embankment. The right-of-way itself does not provide suitable habitat for any of the rare species and the tracks and ties prevent turtles and amphibians from moving across the right-of-way except through the culverts. Only the out-of-service portions of the Stoughton Line (Stoughton Alternative) where tracks and ties have been removed (generally, south of Prospect Street in Easton) and Whittenton Branch (Whittenton Alternative) provide suitable unrestricted migratory habitat for rare species.

No-Build (Enhanced Bus) Alternative

The No-Build Alternative would consist of enhancing current bus service along existing roads and highways. The following three existing park-and-ride facilities would be modified as part of the No-Build Alternative:

- The West Bridgewater Park-and-Ride, located near the southwest corner of the intersection of Routes 106 and 24
- The Mount Pleasant Street Park-and-Ride, located on the northwest corner of the intersection of King's Highway and Route 140 in New Bedford
- The Silver City Galleria Park-and-Ride, located adjacent to the Silver City Galleria shopping mall in Taunton

None of the proposed park-and-ride facilities are within Estimated and Priority Habitats. Therefore, none of the components of the No-Build Alternative are expected to impact rare species and/or their habitat.

Southern Triangle (Common to All Rail Alternatives)

Portions of the rail lines within the southern part of the South Coast Rail study area are common to all Build Alternatives. These rail lines form a roughly triangular shape running south from Weir Junction through Myricks Junction to New Bedford along the New Bedford Main Line, and from Myricks Junction to Fall River along the Fall River Secondary, and are therefore referred to as the Southern Triangle. The following sections describe the potential impacts to rare species that may result from new construction for these two components of the Build Alternatives. The southern part of the South Coast Rail study area is encompassed by the other Build Alternative described in subsequent sections.

New Bedford Main Line Rail Segment

The New Bedford Main Line rail segment would require upgrading and reconstructing the existing freight rail tracks (Figures 4.15-4-8). Two new train stations would be constructed in New Bedford (King's Highway and Whale's Tooth) and one in Taunton (Taunton Depot). Double-track sections would be constructed around King's Highway Station, and a combination of double and triple-track would be constructed from Weir Junction to Myricks Junction. Under the electrification alternatives, four traction power stations would be built along this track segment. Impacts to rare species potentially resulting from developing the new stations and layover facilities are discussed later in this section.

Based on the 2008 NHESP Atlas, the New Bedford Main Line crosses three NHESP Priority and Estimated Habitats (PH1093/EH951, PH1158/EH372, and PH1349/EH1). These habitats include the Cotley River, Cedar Swamp River, Assonet Cedar Swamp/Great Cedar Swamp, and the Acushnet Cedar Swamp (Figures 4.15-8). No ACECs are crossed by the New Bedford Main Line. Both direct and indirect impacts as they relate to this rail segment are described below.

Direct Impacts of the Rail Build Alternatives: New Bedford Main Line Rail Segment

The New Bedford Main Line is an active railroad, and the majority of the improvements would occur within the footprint of the existing track. Analysis by NHESP confirms that improvements to the New Bedford Main Line would result in relatively minor impacts to state-listed species. Minor temporary and permanent impacts may occur within narrow strips immediately adjacent to the right-of-way as necessary for track reconstruction and minor re-alignment of track segments in certain areas. The only major change would be an increase in train speed and frequency from the existing use.

Proposed improvements to the New Bedford Main Line rail segment under all Build Alternatives would result in the loss of potential habitat of eight state-listed species that are known to be present within the Priority Habitats crossed by this segment.[35] These species are: eastern box turtle, mocha emerald, Hessel's hairstreak, long-leaved panic-grass, coastal swamp amphipod, pale green pinion moth, mocha emerald and water-willow stem borer moth. Because the polygon covers an extensive area and crosses several diverse habitats, existing conditions are described for individual segments within the polygon.

Northern Limit to Padelford Street—This segment (Figure 4.15-23) is bordered by areas of suitable upland habitat for eastern box turtle. The open soils of the maintenance road, although dense and stony, may be used for nesting although they do not provide optimal habitat. The existing tracks are a barrier to the movement of eastern box turtles.

Reconstructing the existing railbed and tracks would not result in the loss of eastern box turtle habitat nor create a barrier to box turtle movement. The bridge over the Cotley River would be reconstructed to enhance fish and wildlife passage.

Padelford Street to Myricks Street—This segment (Figure 4.15-23) is bordered by areas of suitable upland habitat for eastern box turtle. The open soils of the maintenance road may be used for nesting although they do not provide optimal habitat due to the dense and stony substrate. The existing tracks are a barrier to the movement of eastern box turtles.

Reconstructing the existing railbed and tracks would not result in the loss of eastern box turtle habitat nor create a barrier to box turtle movement. Box turtle movement may be enhanced, as there is one

[35] NHESP letter dated January 8, 2009.

culvert in this segment that would be reconstructed to meet Commonwealth of Massachusetts Stream Crossing Standards.[36]

Myricks Street to Malbone Street—This segment (Figure 4.15-23) is bordered by areas of marginally suitable upland habitat for eastern box turtle. The open soils of the maintenance road, although dense and stony, may be used for nesting although they do not provide optimal habitat. The existing tracks are a barrier to the movement of eastern box turtles.

Reconstructing the existing railbed and tracks would not result in the loss of eastern box turtle habitat nor create a barrier to box turtle movement.

Malbone Street to Southern Limit Assonet Cedar Swamp—This section extends for 1.7 miles (Figure 4.15-24), and is an active freight railroad. The railbed was constructed for a double track, and currently contains a single track and a maintenance roadway. The railbed is an elevated berm above wetlands for much of its length, passing through a complex of deciduous forested wetlands, Atlantic white cedar swamp, and more open shrub-dominated swamp. Two perennial streams (Pierce Brook and the Cedar Swamp River) cross under the railbed and may provide habitat for the mocha emerald (*Somatochlora linearis*).

This segment is bordered by some areas of suitable upland habitat for eastern box turtle. The open soils of the maintenance road, although dense and stony, may be used for nesting although they do not provide optimal habitat. The existing tracks are a barrier to the movement of eastern box turtles. The adjacent wetlands also provide habitat for Hessel's hairstreak (in Atlantic white cedar trees) and the mocha emerald dragonfly may breed in adjacent streams.

Reconstructing the existing railbed and tracks would not result in the loss of eastern box turtle habitat nor create a barrier to box turtle movement. Box turtle movement may be enhanced, as there are culverts in this segment that would be reconstructed to meet Commonwealth of Massachusetts Stream Crossing Standards,[37] between-the-ties crossings would be added, and the Cedar Swamp River bridge would be reconstructed with wildlife shelves.

Reconstructing the railbed would result in some wetland impact in this section, affecting the habitat of Hessel's hairstreak. Atlantic white cedars are present at low to medium densities in Wetland LK-6, east of the railbed, between the Pierce Brook and the Cedar Swamp River. The northernmost trees are located at wetland flag LK6 219 (STA 2184+50), and are approximately 6 feet east of the wetland flag. The southernmost trees are located at the Cedar Swamp River, LK6-101 (STA 2225). The Atlantic white cedar community spans a distance of approximately 4,000 linear feet. Trees are primarily growing on the east side of the perimeter ditch, 5 to 6 feet west of the wetland flags. There are occasional trees on the railbed side of the ditch. The Atlantic white cedars occur at low densities within a predominantly red maple forested wetland, and co-occur with tupelo, white pine, highbush blueberry, dangleberry , sweet pepperbush, and greenbriar (*Smilax rotundifolia*). The number of trees observed on, or within 10 feet of the railbed along this 4,000 foot distance were not counted. Trees were generally single, or in groups of three to five, and spaced 50 to 100 feet apart.

[36] River and Stream Crossing Partnership. 2011. Massachusetts River and Stream Crossing Standards. The University of Massachusetts- Amherst (College of Natural Sciences), The Nature Conservancy, Massachusetts Division of Ecological Restoration- Riverways Program, American Rivers, and others. August 2004; revised March 1, 2006; revised March 1, 2011; corrected January 31, 2012.

[37] River and Stream Crossing Partnership. 2011. Massachusetts River and Stream Crossing Standards. The University of Massachusetts- Amherst (College of Natural Sciences), The Nature Conservancy, Massachusetts Division of Ecological Restoration- Riverways Program, American Rivers, and others. August 2004; revised March 1, 2006; revised March 1, 2011; corrected January 31, 2012.

None of the proposed filled wetland within this segment provides suitable habitat for the mocha emerald. Improving culverts and bridges within this segment could have temporary construction-period impacts to mocha emerald habitat, but would result in an overall improvement by replacing culverts with open-bottom structures.

Howland Road Area (PH 1158/EA 372)—This segment (Figure 4.15-24) is bordered by areas of suitable upland habitat for eastern box turtle. The open soils of the maintenance road, although dense and stony, may be used for nesting although they do not provide optimal habitat. The existing tracks are a barrier to the movement of eastern box turtles. There are no open coastal plain pond or sandy wetland habitats adjacent to the railbed that provide suitable habitat for long-leaved panic-grass. Within the portion of the polygon (PH1158) crossed by the New Bedford Main Line, one data-sensitive species is also known to be present.[38]

Reconstructing the existing railbed and tracks would not result in the loss of eastern box turtle habitat nor create a barrier to box turtle movement.

Acushnet Cedar Swamp (PH 1349/EH 1)—The polygon with Priority Habitat (PH1349) includes the Acushnet Cedar Swamp State Reservation, which is an approximately 1,000-acre property located in New Bedford and Dartmouth, north of the New Bedford Airport (Figures 4.15-25-26). Within the part of the Acushnet Cedar Swamp and adjacent areas crossed by the New Bedford Main Line, four state-listed species (eastern box turtle, coastal swamp amphipod, pale green pinion moth, and water-willow stem borer moth) are known to be present.[39]

This polygon extends for approximately 3 miles through Freetown and New Bedford. Because the polygon covers an extensive area and crosses several diverse habitats, existing conditions are described for individual segments within the polygon.

Northern Limit Acushnet Cedar Swamp to Chipaway Road—This 1,600-foot section (Figure 4.15-25) is an active freight railroad segment is bordered by areas of suitable upland habitat for eastern box turtle. The open soils of the maintenance road, although dense and stony, may be used for nesting although they do not provide optimal habitat. The existing tracks are a barrier to the movement of eastern box turtles. Ditches and wetlands adjacent to the right-of-way may provide suitable habitat for the coastal swamp amphipod. Adjacent wetlands may also provide suitable habitat for the pale pinon moth and the water-willow stem borer moth.

Reconstructing the existing railbed and tracks would not result in the loss of eastern box turtle habitat nor create a barrier to box turtle movement.

Reconstructing the railbed would result in some wetland impact in this section, potentially affecting the habitat of the three invertebrate species. Approximately 100 square feet of suitable wetland habitat would be temporarily altered for construction.

The impact to water-willow stem borer moth and pale green pinion moth habitat would be mitigated by restoring the altered wetlands within the Acushnet Cedar Swamp segment with the appropriate host plant species (water-willow, highbush blueberry, winterberry, sweet pepperbush).

[38] NHESP letter dated January 8, 2009.
[39] NHESP letter dated January 8, 2009.

Chipaway Road to Samuel Barnett Boulevard—This 1.2 mile section (Figure 4.15-25) is an active freight railroad segment bordered by areas of suitable upland habitat for eastern box turtle. The open soils of the maintenance road, although dense and stony, may be used for nesting although they do not provide optimal habitat. The existing tracks are a barrier to the movement of eastern box turtles. Ditches and wetlands adjacent to the right-of-way may provide suitable habitat for the coastal swamp amphipod. Adjacent wetlands may also provide suitable habitat for the pale pinon moth and the water-willow stem borer moth.

Reconstructing the existing railbed and tracks would not result in the loss of eastern box turtle habitat nor create a barrier to box turtle movement.

Reconstructing the railbed would result in some wetland impact in this section, potentially affecting the habitat of the three invertebrate species. Approximately 11,691 square feet of forested and shrub-dominated wetland in four wetlands would be lost due to filling, and an additional 6,899 square feet of wetland habitat would be temporarily altered for construction.

The impact to water-willow stem borer moth and pale green pinion moth habitat would be mitigated by restoring the altered wetlands within the Acushnet Cedar Swamp segment (6,899 square feet) with the appropriate host plant species (water-willow, highbush blueberry, winterberry, sweet pepperbush).

Samuel Barnett Boulevard to Route 140—This 1.5 mile section (Figure 4.15-25-26) is an active freight railroad segment bordered by areas of suitable upland habitat for eastern box turtle. The open soils of the maintenance road, although dense and stony, may be used for nesting although they do not provide optimal habitat. The existing tracks are a barrier to the movement of eastern box turtles (although it is unlikely that box turtles occur east of the right-of-way due to extensive development). Ditches and wetlands adjacent to the right-of-way may provide suitable habitat for the coastal swamp amphipod. Adjacent wetlands may also provide suitable habitat for the pale pinon moth and the water-willow stem borer moth.

A transfer power substation is proposed in this segment, immediately south of the powerline right-of-way that parallels Samuel Barnet Boulevard. This would result in the loss of 1.25 acres of potential eastern box turtle habitat.

Reconstructing the existing railbed and tracks would not result in the loss of eastern box turtle habitat nor create a barrier to box turtle movement. Reconstructing the railbed would result in some wetland impact in this section, potentially affecting the habitat of the three invertebrate species. Approximately 1,043 square feet of forested and shrub-dominated wetland in one wetland would be lost due to filling, and an additional 2,859 square feet of suitable wetland habitat would be temporarily altered for construction. Improving culverts within this segment could have temporary construction-period impacts to coastal swamp amphipod habitat, but would result in an overall improvement by replacing culverts with open-bottom structures.

The impact to water-willow stem borer moth and pale green pinion moth habitat would be mitigated by restoring the altered wetlands within the Acushnet Cedar Swamp segment (2,859 square feet) with the appropriate host plant species (water-willow, highbush blueberry, winterberry, sweet pepperbush).

Indirect Impacts of the Rail Build Alternatives: New Bedford Main Line Rail Segment

Upgrading New Bedford Main Line Rail Segment would result in marginal loss of nesting, foraging, and wintering habitat for rare species. There would be no habitat fragmentation because losses would be limited to narrow strips at the edge of the existing railroad ballast. The loss of a small percentage of habitat is not anticipated to affect the long-term persistence of these species populations given the large area of suitable habitat for these species in, and in the vicinity of, the project areas. This is especially the case for eastern box turtles which are habitat generalists and can use other adjacent areas, such as cleared land and scrub-shrub, as basking and foraging habitat.

This alternative would require modification and reconstruction of freight rail bridges across the Taunton River, potentially with temporary impacts to Atlantic sturgeon (*Acipenser oxyrhinchus*) habitat. On December 4, 2008, a letter was submitted to the National Marine Fisheries Service (NMFS) requesting information on any threatened and endangered fisheries resources located within the project area. The response from NMFS received on January 12, 2009, stated that there are no federally endangered fisheries resources present in the Taunton River. Although Atlantic sturgeons are known to be present in the Taunton River during the summer months, they are typically found at the mouth of the river with occasional reports of sturgeon venturing further upstream. NMFS noted that it is unlikely that this species occurs in the vicinity of the proposed project (see correspondence in Appendix 4.15-A).

Since the publication of the DEIS, the New York Bight Distinct Population Segment of Atlantic sturgeon was listed as endangered species under the ESA by the NMFS on April 6, 2012.[40] Therefore, the Corps coordinated with NMFS to determine whether the Build Alternatives would affect this species. However, the NMFS stated in their May 13, 2013 response letter it is unlikely that any species listed under their jurisdiction will be exposed to any direct or indirect effects of the proposed South Coast Rail project, including the Atlantic sturgeon (see correspondence in Appendix 4.15-A). Therefore, further Section 7 consultation with NMFS is not necessary.

In addition, NHESP, in their comment letter on the ENF[41] and in subsequent consultations, has not identified adverse impacts to the Atlantic sturgeon.

Indirect impacts to rare species associated with improvements to the New Bedford Main Line Rail Segment under the Build Alternatives include:

- Improvements to migration for terrestrial wildlife, because reconstructing these tracks presents opportunities to reconstruct existing culverts or bridges to improve wildlife passage (e.g., eastern box turtle) and reduce fragmentation.
- Increase in turtle mortality from being struck by trains if they are able to climb the rail, although this is unlikely because the steel rails represent physical barriers not easily climbed by turtles.
- At grade crossings, when moving between habitats, turtles could die of dehydration if they are trapped between the rails.

[40] Federal Register: February 6, 2012 (Volume 77, Number 24, page 5880-5912), Endangered and Threatened Wildlife and Plants; Threatened and Endangered Status for Distinct Population Segments of Atlantic Sturgeon in the Northeast Region.

[41] Executive Office of Transportation and Public Works, *South Coast Rail Environmental Notification Form*, November 2008.

- Potential increase in mortality of rare species near streams or wetland habitat (mocha emerald, Hessel's hairstreak, coastal swamp amphipod, pale green pinion moth) caused by the use of herbicides. Adherence to the approved Vegetation Management Plan (VMP), as implemented with its YOPs, restricts the use of herbicides in areas adjacent to wetlands or sensitive resources, which would thus reduce such impacts

The habitat requirements of the data-sensitive species found within Priority and Estimated Habitat (PH1158/EH372) have been evaluated, and none occur within or adjacent to the right-of-way. As there are no proposed impacts to habitat of this species, no short- or long-term impacts to such species are anticipated.

Fall River Secondary Rail Segment

The Fall River Secondary rail segment would require upgrading and reconstruction of the existing freight rail tracks (Figures 4.15-27-29). Two new stations would be constructed in Fall River (Battleship Cove and Fall River Depot) and one in Freetown (Freetown). Double-track segments would be constructed in the vicinity of these two stations, while the remainder of the corridor would be maintained as a single-track. Under the electrification alternatives, two traction power stations would be built along this track segment. Traction power stations are small facilities (each approximately one acre or less) that are required at periodic intervals along an electrified rail corridor in order to provide connections to the electricity grid. On the Fall River Secondary, Weaver's Cove East is the favorable location to site a Fall River layover facility.

Based on the 2008 NHESP Atlas, the Fall River Secondary crosses one NHESP Priority and Estimated Habitat (PH1093/EH951). This section of the right-of-way includes several small wetlands along the Assonet River (Figure 4.15-27-29). There are no ACECs crossed by the Fall River Secondary rail segment. The following sections describe both direct and indirect impacts as they relate to the Fall River Secondary rail segment.

Direct Impacts of Rail Build Alternatives: Fall River Secondary Rail Segment

The Fall River Secondary rail segment proposed for use under all Build Alternatives is an active rail road and the majority of the improvements for the Build Alternatives would occur within the footprint of the existing track. Minor temporary and permanent impacts may occur within narrow strips immediately adjacent to the right-of-way as necessary for track reconstruction and minor re-alignment of track segments in certain areas. The only major change would be an increase in train speed and frequency.

Within the part of the Assonet Cedar Swamp (PH1093) and adjacent areas crossed by the Fall River Secondary rail segment, the following three state-listed species are known to be present:[42] eastern box turtle, mocha emerald, and Hessel's hairstreak.

Mitigation for the barrier effect would likely be provided by:

- Reconstructing culverts to meet Commonwealth of Massachusetts Stream Crossing Standards[43]

[42] NHESP letter dated January 8, 2009.

[43] River and Stream Crossing Partnership. 2011. Massachusetts River and Stream Crossing Standards. The University of Massachusetts- Amherst (College of Natural Sciences), The Nature Conservancy, Massachusetts Division of Ecological Restoration- Riverways Program, American Rivers, and others. August 2004; revised March 1, 2006; revised March 1, 2011; corrected January 31, 2012.

- Reconstructing the Cedar Swamp River bridge with wildlife shelves (see Figure 4.14-21a in Chapter 4.14, *Biodiversity, Wildlife, and Vegetation*)

None of the wetlands to be filled provide suitable habitat for the mocha emerald. Improving culverts and bridges within this segment could have temporary construction-period impacts to mocha emerald habitat, but would result in an overall improvement by replacing restricted culverts with open-bottom structures. Reconstructed culverts and other crossings would be designed so as to prevent secondary drainage or other negative alterations to the delicate hydrology of the sensitive wetlands on either side of the right-of-way.

Indirect Impacts of Rail Build Alternatives: Fall River Secondary Rail Segment

Upgrading this track would result in marginal loss of nesting, foraging, and wintering habitat for rare species. Analysis by NHESP confirms that improvements to the Fall Secondary rail segment would result in relatively minor impacts to state-listed species. There would be no habitat fragmentation because all habitat losses would be narrow strips at the edge of the existing railroad ballast. The loss of a small percentage of habitat is not anticipated to affect the long-term persistence of these species populations given the large area of suitable habitat for these species in, and in the vicinity of, the project areas. This is especially the case for eastern box turtles which are habitat generalists and can use other adjacent cleared and scrub-shrub areas as basking and foraging habitat

Indirect impacts to rare species associated with this alternative include:

- Improvements to migration for terrestrial wildlife, because reconstructing these tracks presents opportunities to reconstruct existing culverts or bridges to improve wildlife passage (e.g., eastern box turtle) and reduce fragmentation. During final design, each culvert or bridge that would be removed or replaced would be analyzed in order to avoid causing hydrologic changes.

- Increase in turtle mortality resulting from being struck by trains if they are able to climb the rail, but this is not expected to occur frequently because the steel rails are not easily climbed by turtles.

- At grade crossings, when moving between habitats, turtles could die of dehydration if they are trapped between the rails and are not able to get out.

- Potential increase in mortality of rare species near streams or wetland habitat (e.g., mocha emerald and Hessel's hairstreak) caused by the use of herbicides. Adherence to an approved Vegetation Management Plan (VMP), as implemented in conjunction with Yearly Operating Plans (YOP), restricts the use of herbicides in areas adjacent to wetlands or sensitive resources and would thus reduce such impacts.

Summary of Southern Triangle Impacts

As shown in Table 4.15-7, improvements to the existing railbed would result in the permanent loss of 1.3 acres of wetland and require the temporary alteration of 0.9 acre of wetland, in 16 wetlands. In three locations (Wetland LK-7 on the New Bedford Main Line; Wetland LKF-1, and Wetland FRF-1B on the Fall River Secondary) culverts conveying perennial or intermittent streams under the berm would be extended. Bridges over the Cedar Swamp River would be reconstructed, with no work in the water. While portions of Southern Triangle are bordered by areas of suitable upland habitat for eastern box

turtle, the existing tracks are a barrier to the movement of eastern box turtles. Accordingly, reconstructing the existing railbed and tracks would not result in the loss of eastern box turtle habitat nor create a barrier to box turtle movement.

Table 4.15-7 Southern Triangle Impacts within Estimated and Priority Habitat

Location/Species	Upland Habitat Loss (ac)	Wetland	Wetland Loss (sf)	Temporary Construction Impact (sf)	Comments

Total[2]	NA		11,691	9,758	

1 Not applicable, no loss of suitable habitat.
2 Inclusive of all species listed under each location.

Long-leaved panic-grass is known to occur within the polygon that includes a wooded swamp area and the Cedar Swamp River (PH1158). Long leaved panic grass is associated with coastal plain pond shore communities, and occurs in moist open sandy habitats on the coastal plain. No suitable habitat has been identified in proximity to the rail right-of-way.

Stoughton Electric Alternative

The Stoughton Electric Alternative north of the Southern Triangle would be comprised of a portion of the Northeast Corridor and the Stoughton Line (Figures 4.15-12-15). This alternative would use the Northeast Corridor from South Station to Canton Junction. At Canton Junction, trains would continue on the existing, active Stoughton Line as far south as the relocated Stoughton Station. Commuter rail service would be extended south from Stoughton Station, using an out-of-service railroad bed, through Raynham Junction to Weir Junction in Taunton. This alignment joins the New Bedford Main Line at Weir Junction, the northern end of the Southern Triangle. This evaluation focuses on the existing and the extended Stoughton Line segment. The Priority and Estimated Habitats crossed by the Northeast Corridor north of Canton Junction would not be impacted under the Stoughton Alternative.

The existing Stoughton Line commuter rail track from Canton Junction to Stoughton would be upgraded for the Stoughton Electric Alternative. This includes improvements to existing active freight or rail lines from Canton Junction to Stoughton Station, and from Dean Street to Weir Junction. This alternative also requires track construction on out-of-service or abandoned rights-of-way between Stoughton Station and Dean Street.

One existing train station along the Stoughton Line would be reconstructed (Canton Center) and six new train stations would be constructed (Stoughton, Easton Village, North Easton, Raynham Park, Taunton, and Taunton Depot). Three traction power stations would be built along this track segment. No new layover facilities would be constructed along this segment. Potential impacts to rare species from reconstructing the existing and developing the new stations are discussed later in this section.

Based on the 2008 NHESP Atlas, the Stoughton Line crosses two Priority and Estimated Habitats (PH1392/EH59 and PH1297/EH1077). These Priority habitats include land within the Hockomock Swamp ACEC and Pine Swamp respectively. The following sections describe both direct and indirect impacts as they relate to this alternative; the two Southern Triangle components were previously discussed.

Direct Impacts of the Stoughton Electric Alternative: Stoughton Rail Segment

The alignment of the proposed Stoughton Alternative follows a previously developed railroad corridor. Minor temporary and permanent impacts may occur within narrow strips immediately adjacent the right-of-way during track reconstruction and re-alignment. Most of the impacts are expected along the track construction on out-of-service or abandoned rights-of-way between Stoughton Station and Dean Street.

The Stoughton Alternative would result in the loss of potential habitat of five state-listed species (Blanding's turtle; eastern box turtle; blue-spotted salamander, gypsywort and Hessel's hairstreak) and would interrupt a migratory corridor used by turtles and blue-spotted salamanders (Table 4.15-8). These species are known to be present within the Priority Habitats crossed by this segment.[44]

[44] NHESP letter dated January 8, 2009.

Table 4.15-8 Stoughton Alternative Impacts within Estimated and Priority Habitat

Location/Species	Upland Habitat Loss (ac)	Wetland (ID)	Wetland Loss (sf)	Temporary Construction Impact (sf)	Comments
Stoughton Alternative-Hockomock Swamp Area (PH1392)					
Blanding's turtle (*Emydoidea blandingii*)	12.5	EA-77	0	217	Forested and shrub wetland bordering intermittent stream CVP 1665
Blue-spotted salamander (*Ambystoma laterale*)	7.5	EA-77	0	217	Forested and shrub wetland bordering intermittent stream CVP 1665
Eastern box turtle (*Terrapene carolina carolina*)	11.4	NA[1]	NA	NA	Successional upland vegetation, unvegetated gravel railroad berm, impede movement
Stoughton Alternative-Pine Swamp Area (PH1297)					
Hessel's hairstreak *(Callophrys hesseli)*	NA	R-12.2	18,578	14,537	Forested wetland containing Atlantic White Cedar – estimated loss of 35 trees

1 Not applicable, no loss of suitable habitat.

Hockomock Swamp ACEC (PH1392)—This polygon extends for a total of 5.5 miles from Purchase Street in Easton to I 495 in Raynham. The polygon with Priority Habitat (PH1392) includes the Hockomock Swamp ACEC, which is approximately 16,950 acres of land in Bridgewater, Easton, Norton, Raynham, Taunton, and West Bridgewater (Figures 4.15-21-22). The ACEC is fragmented by several major transportation corridors, including Route 24, I-495, Route 138, Route 106, and other major roadways, and the railroad right-of-way itself, and it includes substantial upland areas within the watershed of the Hockomock Swamp. These uplands include land developed in commercial and residential uses as well as undeveloped forested upland and farmland.

The DCR describes the ACEC as one of the most extensive inland wildlife habitats in southeastern Massachusetts. The Atlantic white cedar swamp and acidic fen wetland communities scattered throughout the Hockomock Swamp ACEC are considered to be outstanding examples of these unique natural communities. Within the part of the ACEC crossed by the Stoughton Alternative, four state-listed species (blue-spotted salamander, Blanding's turtle, eastern box turtle, and gypsywort) are known to be present.[45] The Atlantic white cedar stands also provide potential habitat for Hessel's hairstreak. Because the polygon covers an extensive area and crosses several diverse habitats, existing conditions are described for individual segments within the polygon.

Purchase Street to Prospect Street—The railroad right-of-way within this 0.75 mile section (Figure 4.15-21) consists of a narrow (6 feet wide) gravel pathway on the former railbed. This segment is bordered by

[45] NHESP letter dated January 8, 2009.

areas of suitable upland habitat for eastern box turtle. Eastern box turtles, if present, may move across the right-of-way to access suitable habitat areas on either side. NHESP also considers this segment to be within the potential habitat of Blanding's turtles.

Reconstructing the railbed would result in the loss of vegetation along the edges of the path that may provide cover for turtles (3.1 acres) and would create a barrier to the movement of turtles between potential habitats east and west of the railbed.

Prospect Street to Foundry Street—The railroad right-of-way within this 0.9 mile section (Figure 4.15-21) consists of a 10-foot wide gravel pathway on the former railbed (with evidence of use by ATVs). For the northern 0.3 mile, the right-of-way is bordered by forested upland and wetland on the west, associated with Black Brook, and by a golf course on the east. For the next 0.3 mile, the right-of-way passes between two golf courses. The southern third passes between two large wetlands (EA 82, EA 81). A certified vernal pool is east of the right-of-way just north of Foundry Street. During the 2001 field study, a single blue-spotted salamander was trapped in this area.

This segment is bordered by areas of suitable upland habitat for eastern box turtles and wetlands potentially used by Blanding's turtles. Sandy soils in the golf courses may provide nesting habitat for either turtle species, which, if present, may move across the right-of-way to access suitable habitat areas on either side.

Reconstructing the railbed and track within this section would create a barrier to the movement of Blanding's turtles between the two golf courses and potentially suitable habitat on either side of the right-of-way. This would also create a barrier to the movement of blue-spotted salamanders in the southernmost 800 feet of this section.

Reconstructing the railbed would also result in the loss of vegetation, where the right-of-way is not occupied by a dirt path. The path in this section averages 10 feet wide. The loss of natural vegetation providing cover to turtles would be approximately 2.8 acres; the loss of natural vegetation providing cover or upland habitat for blue-spotted salamanders would be 0.7 acre.

Mitigation for the barrier effect would likely be provided by:

- Reconstructing the Black Brook bridge with wildlife shelves
- Reconstructing culverts to meet Commonwealth of Massachusetts Stream Crossing Standards[46]
- Installing between-the-ties crossing structures
- Installing wildlife crossing culverts

Foundry Street to Power Line—The railroad right-of-way within this 0.6 mile section (Figure 4.15-21) consists of a wide gravel pathway on the former railbed (with evidence of use by ATVs. The right-of-way passes through a white pine forested upland and deciduous forested upland and wetlands (EA 77, EA 78) in the northern half and deciduous forested wetland (EA 63, EA 64) in the southern half. Several certified

[46] River and Stream Crossing Partnership. 2011. Massachusetts River and Stream Crossing Standards. The University of Massachusetts- Amherst (College of Natural Sciences), The Nature Conservancy, Massachusetts Division of Ecological Restoration- Riverways Program, American Rivers, and others. August 2004; revised March 1, 2006; revised March 1, 2011; corrected January 31, 2012.

vernal pools are within this section, on both sides of the railbed. At the southern end of this section, the railbed crosses a right-of-way for an overhead power line and the powerline maintenance road. The railbed consists of an open, wide sandy road adjacent to wetlands dominated by woody shrubs and Phragmites.

This segment is bordered by areas of suitable upland habitat for eastern box turtle, wetlands potentially used by Blanding's turtle, and vernal pools used as breeding habitat by blue-spotted salamanders. Sandy soils in the gravel pit, or in the ballfield, may provide nesting habitat for either turtle species. All three species may move across the right-of-way to access suitable habitat areas on either side.

The northernmost 1,200 feet of this segment would be the approach to the trestle. In this approach segment, the track would slope up, and retaining walls would be used to minimize fill. A traction power substation would be constructed east of the right-of-way, within an area of white pine forest or in the ballfield. The track would be on the trestle for the majority of this section, and the only impacts would result from vegetation removal. Reconstructing the railbed and track within the northernmost 1,200 feet of this section would create a barrier to the movement of Blanding's turtles and blue spotted salamanders. However, these species could cross through the enhanced culvert or could walk south and pass under the trestle, guided by the retaining walls.

Reconstructing the railbed and constructing the trestle would also result in the loss of vegetation, where the right-of-way is not occupied by a dirt path. The path in this section averages 15 feet wide (the width ranges from 10 to 30 feet). The loss of natural vegetation providing cover to turtles or salamanders would be approximately 1.6 acres. There would be no wetland impacts in this section, except as needed to reconstruct the culvert connecting wetlands EA-77 and EA-78 (both of which contain vernal pools).

Mitigation for the barrier effect would likely be provided by:

- Reconstructing the culvert to meet Commonwealth of Massachusetts Stream Crossing Standards[47]
- Retaining walls would guide animals around the at-grade section north of the trestle
- Daylighting culverts in this segment (beneath the proposed trestle)

Power Line to Former Raynham Greyhound Park—The railroad right-of-way within this 1.7 mile section (Figures 4.15-21-22) consists of a wide gravel pathway on the elevated former railbed (with evidence of use by ATVs). The railbed passes through primarily forested red maple-dominated wetlands, although there is an open emergent marsh and shrub swamp west of the railbed (south of the powerline), a large vernal pool east of the railbed, and an Atlantic white cedar swamp located entirely west of the railbed and extending for approximately 0.6 mile north of the Raynham Greyhound Park. Several vernal pools occur within this section.

This segment is bordered by wetlands potentially used by Blanding's turtles, wetlands and uplands potentially used by eastern box turtles, and vernal pools used as breeding habitat by blue-spotted salamanders. Sandy soils under the powerline may provide nesting habitat for either turtle species. All three species may move across the right-of-way to access suitable habitat areas on either side.

[47] Ibid.

Gypsywort occurs in the open emergent wetland west of the railbed, south of the power line. There would be no impact to this population.

Reconstructing the railbed would result in the loss of upland forest vegetation, where the right-of-way is not occupied by a dirt path. The path in this section averages 10 feet wide. The loss of natural vegetation providing cover to turtles or salamanders would be approximately 5 acres.

The southernmost section of this segment would be the approach to the trestle. In this approach segment, the track would be at-grade, sloped up to the trestle. Although there would be impacts to wetlands north of the Raynham Greyhound Park road crossing, these wetlands do not provide habitat for Blanding's turtle, eastern box turtle, or blue-spotted salamander. One culvert in this section would be reconstructed to meet Commonwealth of Massachusetts Stream Crossing Standards.[48]

Although the trestle does not affect wildlife movement, the six culverts within the trestle section would be "daylighted" to improve their function as wildlife crossings.

Former Raynham Greyhound Park to Bridge Street—The railroad right-of-way within this 1.1 mile section (Figure 4.15-22) is within a cut through the landscape, making the right-of-way a topographic low point. It consists of a wide gravel roadway on the former railbed, with evidence of extensive use by ATVs. The northernmost 1,400 feet of this section is bordered to the east by an industrial park, with a detention basin that drains onto the right-of-way. An existing stream (formerly an agriculture drainage ditch) flowing from the west drains into a ditch on the west side of, and parallel to, the track. This drainageway has become blocked, and thus the combined flow from the ditch and the detention basin on the east, has been identified as a perennial stream flowing north within the railbed. The railbed passes through primarily upland forest, and passes through one small wetland system (R 61, R 59). A maintained powerline is located on the east side of the railbed. A complex of potential vernal pools occurs on both sides of the railbed approximately 1,500 feet north of Bridge Street.

This segment is bordered by areas of suitable upland habitat for eastern box turtle. Eastern box turtles, if present, may move across the right-of-way to access suitable habitat areas on either side.

Reconstructing the railbed and track within this section would create a barrier to the movement of eastern box turtles between potentially suitable habitat on either side of the right-of-way. Reconstructing the railbed would also result in the loss of vegetation, where the right-of-way is not occupied by a dirt path. The path in this section averages 10 feet wide. The loss of natural vegetation providing cover to turtles would be approximately 11.4 acres as calculated by NHESP, including the gravel pathway.

Mitigation for the barrier effect would likely be provided by installing between ties crossing structures.

Bridge Street to I-495—The railroad right-of-way within this 0.25 mile section consists of a wide gravel path on the former railbed. The railbed is bordered by a small park and ballfield to the east, and by residential development on both sides. Elm Street crosses the right-of-way mid-way between Bridge Street and the highway.

[48] Ibid.

Although included in the priority habitat polygon, this segment is not bordered by areas of suitable upland habitat for eastern box turtle. Accordingly, there are no impacts to eastern box turtle in this section.

Pine Swamp (PH1298)—The railroad right-of-way through Pine Swamp, between King Phillip Street and East Britannia Street (Figure 4.15-22), is on an elevated berm for the northern 0.5-mile section and at-grade in the southern section. The railbed contains a narrow (3 to 4 feet wide) path and a powerline owned by the Taunton Municipal Light Company. The northernmost 500 feet is bordered by residential development on the west side. An auto junkyard is east of the right-of-way at the East Britannia Street crossing. The railbed and adjacent powerline are predominantly vegetated with shrubs and herbaceous species, including giant reed grass. Adjacent areas are forested or shrub-dominated wetlands (including a large stand of giant reed grass). The forested wetland east of the railbed is dominated by deciduous trees, while the forested wetland west of the railbed is dominated by Atlantic white cedar.

Atlantic white cedar trees, present in the wetland west of the railbed and on the railbed itself, provide breeding habitat for the Hessel's hairstreak butterfly. Atlantic white cedars are present at low densities in Wetland RA12.2, west of the railbed, between the southern Pine Swamp Brook crossing and the northern Pine Swamp Brook crossing. The southernmost trees are located at wetland flag RA12.2-154 (STA 1729), and are approximately 6 feet west of the wetland flag. The northernmost trees are located at wetland flag RA12.2-138 (STA 1711). The Atlantic white cedar community spans a distance of approximately 1,800 linear feet. Trees are primarily growing on the west side of the perimeter ditch, 5 to 6 feet west of the wetland flags. There are occasional trees on the railbed side of the ditch. The Atlantic white cedars occur at low densities within a predominantly red maple forested wetland, and co-occur with tupelo, white pine, highbush blueberry, dangleberry), sweet pepperbush, and poison sumac . A total of 35 trees were observed on, or within 10 feet of the railbed along this 1,800 foot distance.

Reconstructing the railbed would result in the loss of vegetation, where the right-of-way is not occupied by a dirt path. The path in this section averages 3 to 4 feet wide. The loss of natural vegetation containing Atlantic white cedars would be approximately 18,578 square feet, and approximately 14,537 square feet of wetland would be temporarily altered for construction. This work would result in the loss of approximately 35 Atlantic white cedar trees (the habitat of Hessel's hairstreak).

This impact would be mitigated by restoring the altered wetlands within the Pine Swamp segment (14,537 square feet) with Atlantic white cedars.

The Stoughton Line would potentially impact rare species habitat within the Hockomock Swamp ACEC, which encompasses most of Priority and Estimated Habitat polygon (PH1392/EH59). Habitat potentially used by Blanding's turtle, eastern box turtle, blue-spotted salamander, gypsywort and Hessel's hairstreak would be impacted within the Hockomock Swamp ACEC. An additional 11 state-listed species occur within the Hockomock Swamp polygon (PH1392/EH59). Other rare species and their habitat may occur within the polygons or within the contiguous ACECs.

Gypsywort (*Lycopus rubellus*)—The proposed Stoughton Alternative is not anticipated to have any adverse effect on the existing population or habitat of gypsywort, and not likely to result in a "take." The known population is within a wetland adjacent to the railroad berm through the Hockomock Swamp, where the restored tracks would be on an elevated trestle. No work would occur in the wetland where this species occurs.

Hessel's Hairstreak Butterfly (*Callophrys hesseli*)—The proposed Stoughton Alternative would not result in a "take" of Hessel's hairstreak as a result of the loss of breeding habitat (Atlantic white cedar trees) in Pine Swamp. The proposed project would require that the tracks be reconstructed through Pine Swamp. This would require that the existing berm be reconstructed with placement of sub-ballast, ballast, ties and track. As shown in Figure 4.15-22, impacts have been minimized through the use of reinforced earth slopes. However, there would be unavoidable impacts to wetlands containing Atlantic white cedar trees, as well as Atlantic white cedar trees growing on the existing upland berm. However, no Atlantic white cedar swamp would be affected in the Assonet Cedar Swamp. The total estimated loss of habitat for Hessel's hairstreak (wetland [R 12.2] and upland) is approximately 35 Atlantic white cedar trees, assuming the impacted areas are utilized by the Hessel's hairstreak.

Mocha Emerald Dragonfly (*Somatochlora linearis*)—The proposed Stoughton Alternative would result in minor impacts to potential mocha emerald dragonfly habitat within the Assonet Cedar Swamp polygon but would not result in a "take" as determined by NHESP. Improvement to the existing railbed would result in the permanent loss of 1.04 acres of wetland and could require the temporary alteration of an additional 0.7 acre of wetland. These losses of wetlands would be in narrow strips at the existing edge of the railroad berm.

Pale Green Pinion Moth (*Lithophane viridipalle*)—The proposed Stoughton Alternative would result in minor impacts to potential pale green pinion moth habitat within the Acushnet Cedar Swamp polygon but would not result in a "take" as determined by NHESP. Proposed improvements to the existing railbed would result in the permanent loss of 0.26 acre of wetland and could require the temporary alteration of an additional 0.22 acre of wetland, in five wetlands. This loss of wetlands would be in a narrow strip at the existing edge of the railroad berm.

Water-willow Stem Borer Moth (*Papaipema sulphurata*)—The proposed Stoughton Alternative would result in minor impacts to potential water-willow stem borer moth habitat within the Acushnet Cedar Swamp polygon but would not result in a "take" as determined by NHESP. Improvements to the existing railbed would result in the permanent loss of 0.26 acre of wetland and could require the temporary alteration of an additional 0.22 acre of wetland, in five wetlands. This loss of wetlands would be in a narrow strip at the existing edge of the railroad berm.

Coastal Swamp Amphipod (*Synurella chamberlaini*)—The proposed Stoughton Alternative would result in minor impacts to potential coastal swamp amphipod habitat within the Acushnet Cedar Swamp polygon but would not result in a "take" as determined by NHESP. The proposed improvements to the existing railbed would result in the permanent loss 0.26 acre of wetland and could require the temporary alteration of an additional 0.22 acre of wetland, in five wetlands. This loss of wetlands would be in a narrow strip at the existing edge of the railroad berm.

Blue-spotted Salamander (*Ambystoma laterale*)—The proposed Stoughton Alternative would result in a "take" of blue-spotted salamander as a result of reconstructing the railbed between Foundry Street and the powerline. Although the reconstruction would not result in the loss of vernal pool habitat used for reproduction, there would be a loss of 7.5 acres of forested upland habitat potentially used as non-breeding and overwintering habitat for construction of the transfer power substation south of Foundry Street. Constructing the tracks at grade and on the approach to the trestle would create a barrier to the movement of salamanders between breeding and non-breeding habitat along approximately 1,500 feet of this section, and an additional 800 feet north of Foundry Street. The remaining length of the railbed would continue to allow unimpeded movement across the berm.

Considering blue-spotted salamanders are rarely encountered above ground, except as adults during their early spring breeding season, or as metamorphosed juveniles in the late summer, limiting proposed work in know areas where this species is present during these periods may minimize impacts to this species. Furthermore, the installation of between-the-ties crossing structures and other mitigation measures would aid in minimizing impacts to this species.

Construction of the approach to the trestle at the northern end would require temporarily impacting approximately 217 square feet of Wetland EA-77, a forested and shrub-dominated wetland bordering an intermittent stream. This wetland contains a vernal pool and provides breeding habitat for vernal pool amphibians.

Construction of the trestle would result in the loss of natural vegetation adjacent to vernal pools, which has the potential to affect water temperature and detrital influxes. However, the loss of canopy would be restricted to one side of each vernal pool and would not affect the capacity of the pool to continue to provide breeding habitat. In addition, the approximately north-south orientation of the right-of-way would limit means that remnant trees would provide adequate shade except during the few hours before and after noon.

Blanding's Turtle (*Emydoidea blandingii*)—The principal effect of the Stoughton Alternative to Blanding's turtles would be to impede the movement of turtles from east to west, particularly in the area where golf courses abut the rail right-of-way on both sides. This could potentially affect access between adult habitat and nesting habitats. There would be no fill in wetlands that provide potential Blanding's turtle habitat (deep marshes or pools with shrub cover). The proposed Stoughton Alternative would require that the out-of-service tracks be reconstructed through the area identified as potential Blanding's turtle habitat. The track would be reconstructed at-grade from Depot Street to approximately 0.28 mile south of Foundry Street. The reconstructed track would interfere with the movements of Blanding's turtles between wetland and upland (potential breeding) habitats on either side of the right-of-way for a total distance of 0.72 mile from Purchase to Prospect Street, 0.87 mile from Prospect to Foundry Street, and 0.28 mile from Foundry Street to the start of the trestle, for a total of 1.9 miles of barrier effect. South of this point, the track would be on an elevated trestle and would not impede turtle movements. The installation of between-the-ties crossing structures and other mitigation measures in concert with potential time of year construction limitations would aid in minimizing impacts to this species.

Construction of the trestle would result in the loss of natural vegetation adjacent to vernal pools, which has the potential to affect water temperature and detrital influxes. However, the loss of canopy would be restricted to one side of each vernal pool and would not affect the capacity of the pool to continue to provide habitat for Blanding's turtles. There would be a total loss of upland vegetation of 12.5 acres consisting of successional vegetation within the right-of-way.

Eastern Box Turtle (*Terrapene carolina carolina*)—The principal effect of the Stoughton Alternative to eastern box turtles would be to impede the movement of turtles from east to west, particularly in the area where undeveloped forested land abuts the right-of-way on both sides. The reconstruction of existing freight rail tracks is not anticipated to affect turtle movement. There would be a loss of 11.4 acres of successional upland vegetation potentially utilized by eastern box turtles as well as the unvegetated gravel railroad berm. The Stoughton Alternative would require that the tracks be reconstructed in the section of the Hockomock Swamp (south of the former Raynham Greyhound Track) that provides eastern box turtle habitat. This work would result in a "take" as the tracks would preclude

the movement of eastern box turtles across the right-of-way, between suitable habitat areas, for a distance of 0.9 mile.

Indirect Impacts of the Stoughton Electric Alternative: Stoughton Rail Segment

The Stoughton Line is an inactive line without tracks and ties for most of its length. Existing culverts carry streams beneath the railroad embankment and provide migratory habitat to wildlife species. In addition to the culverts, the right-of-way itself provides suitable migratory habitat for rare species because there are no tracks and ties to prevent turtles and amphibians from moving across the right-of-way. The right-of-way does not likely provide significant nesting, breeding, and foraging habitat for rare species. However, as noted by the NHESP, much of the embankment has become reforested since the tracks were removed, and is likely to provide suitable feeding, sheltering, and overwintering habitat for the blue-spotted salamander and eastern box turtle. The GIS analysis did not show any loss of Atlantic white cedar swamp habitat; however, Atlantic white cedars were observed growing on the edges of the rail bed and may provide habitat for Hessel's hairstreak.

Documented nesting of spotted turtles within the right-of-way of the Stoughton segment indicates that portions of the right-of-way may also provide nesting habitat for the Blanding's turtle and eastern box turtle. However, nesting habitat available within or adjacent to the right-of-way is of marginal quality, except for the area beneath the overhead powerlines south of Foundry Street. These areas would be limited to portions of the right-of-way where the canopy is open enough to allow sunlight to incubate the eggs for long enough periods of time for viable survival, but higher-quality nesting habitat is present along the powerline right-of-way. Turtles moving between patches of suitable habitat may also cross the right-of-way. Table 4.15-9 lists the species reported to be found within Priority Habitat polygons and the potential habitat functions that could be impacted.

Table 4.15-9 Whittenton Alterntive Impacts within Estimated and Priority Habitat

Location/Species	Upland Habitat Loss (ac)	Wetland (ID)	Wetland Loss (sf)	Temporary Construction Impact (sf)	Comments
Whittenton Alternative- (PH261)					
Blanding's turtle (*Emydoidea blandingii*)	12.5	EA-77	0	217	Forested and shrub wetland bordering intermittent stream CVP 1665
Blue-spotted salamander (*Ambystoma laterale*)	7.5	EA-77	0	217	Forested and shrub wetland bordering intermittent stream CVP 1665
Eastern box turtle (*Terrapene carolina carolina*)	12.6	NA	NA	NA	Successional upland vegetation, unvegetated gravel railroad berm, impede movement

1 Not applicable, no loss of suitable habitat.

The reconstructed rail infrastructure, in locations where no tracks or ties currently exist, would prevent or impede the movement of Blanding's or eastern box turtles across the right-of-way. This habitat

fragmentation could lead to the loss of genetic diversity and decrease in population size, potentially resulting in the local extirpation of some small populations.[49] Fragmentation of habitat for blue-spotted salamanders could potentially have similar results, although the rail would constitute a barrier to salamander movement at the northern edge of the Hockomock Swamp population area and would not impede movement of salamanders for the remaining 7,000 linear feet of the trestle. No habitat fragmentation is anticipated for state-listed insect species which primarily occur along the active freight rail lines. The trestle would be constructed between south of Foundry Street and north of Raynham Park station site. Additional description of the trestle is included in Section 4.15.3.6.

Indirect impacts to rare species associated with the Stoughton segment of the Stoughton Electric Alternative include:

- Loss of migratory routes (barrier effect) and increase in habitat fragmentation, because construction of this track would occur within undeveloped forested area. Within the Hockomock Swamp (PH1392/EH59), in areas north and south of the trestle, the total barrier effect would be approximately 3.2 miles. The barrier effect would be approximately 1.9 miles potentially used by Blanding's turtle between Depot Street and Foundry Street, approximately 0.4 mile used by blue-spotted salamander between Foundry Street and the northern limit of the trestle, and approximately 0.9 mile used by eastern box turtle between the southern limit of the trestle and Bridge Street. The barrier effect was estimated by calculating the length of the new track through the polygons of Priority and Estimated Habitat. This is a conservative estimate of impact because it is unlikely that the entire length of the proposed new track would cross habitat suitable for migration. It does not account for the construction of culverts or bridges as part of the design that would improve the potential for wildlife passage and reduce fragmentation impacts.

- There is potentially some fragmentation to Hessel's hairstreak habitat caused by widening the canopy gap within the Hockomock Swamp. Maintenance of the powerline corridor along the right-of-way has created an existing canopy gap within the Pine Swamp.

- Increase in turtle mortality from being struck by trains if they are able to climb the rail, but this is unlikely to occur frequently because the steel rails represent a physical barrier not easily climbed by turtles.

- At grade crossings, when moving between habitats, turtles could also die of dehydration if they are trapped between the rails and are not able to get out.

- Clearing within 100 feet of vernal pools could lead to the loss of shade within vernal pool habitat that could be used by the blue-spotted salamander. The vernal pool impacts are evaluated in Chapter 4.14, *Biodiversity, Wildlife, and Vegetation*.

Stoughton Diesel Alternative

No traction power facilities are proposed under the diesel alternative. Therefore, the Stoughton Diesel Alternative, north of Weir Junction, would have approximately 1.9 acres less impact than the Stoughton Electric Alternative. All other rare species impacts are the same as those associated with the Stoughton Electric Alternative.

[49] Steen, D.A. and J.P. Gibbs. 2004. Effects of roads on the structure of freshwater turtle populations. Cons. Biol. 18:1143-1148.

Whittenton Electric Alternative

The Whittenton Electric Alternative is an alignment variant of the Stoughton Electric Alternative. Specifically, at Raynham Junction near the southern end of the right-of-way of the former Stoughton Line, the alignment would divert to the southwest, following the right-of-way of the former Whittenton Branch. This alignment would connect with the existing Attleboro Secondary tracks at Whittenton Junction in Taunton, and then continue toward the southeast to connect with the tracks of the New Bedford Main Line at Weir Junction. The portion of the former Stoughton Line between Raynham Junction and Weir Junction would not be used under the Whittenton Alternative which would avoid crossing the Priority and Estimated Habitat (PH1297/EH11077) associated with Pine Swamp.

One existing train stations along the Stoughton Line would be reconstructed (Canton Center) and six new train stations would be constructed (Stoughton, Easton Village, North Easton, Raynham Park, Taunton Depot, and Dana Street). Four traction power stations would be built along this track segment. No new layover facilities would be constructed along this segment. Potential impacts to rare species from reconstructing the existing and developing the new stations are discussed later in this chapter.

Based on the 2008 NHESP Atlas, the Whittenton Electric Alternative crosses two Priority and Estimated Habitats (PH1392/EH59, and PH261/EH153). These Priority Habitats include land within the Hockomock Swamp ACEC and the Three Mile River ACEC (Figure 4.15-16-17). The following sections describe both direct and indirect impacts as they relate to the Whittenton Alternative; inclusive of the Southern Triangle components.

Direct Impacts of the Whittenton Electric Alternative: Stoughton/Whittenton Rail Segment

The alignment of the proposed Whittenton Alternative follows previously developed railroad corridors along the Attleboro Secondary, Whittenton Branch, and Stoughton Line. Minor temporary and permanent impacts may occur within narrow strips immediately adjacent to the right-of-way during track reconstruction and re-alignment. Most of the impacts are expected along the track construction on out-of-service or abandoned rights-of-way between Stoughton Station and Raynham Junction (Stoughton Line) discussed above, and from to Raynham Junction to Whittenton Junction (Whittenton Branch). Impacts to rare species habitat are not expected along the Attleboro Secondary because it is an existing active rail line and already presents a barrier to wildlife movement.

Along the Whittenton Branch, while the right-of-way road does not constitute wildlife habitat, constructing the railroad would result in additional impacts on either side of the right-of-way. More substantial impacts would occur along the southernmost section of the right-of-way between the access road and Whittenton Junction, where the path is narrower. Area of impact was estimated by measuring the area inside the limit of work (limit of grading) and subtracting the area of the roadway and path, based on available survey information. A total of approximately 1.2 acres of rare species habitat (successional vegetation along the edge of the traveled path) would be permanently impacted as a result of constructing the railroad. All impacted habitat is upland area except for approximately 460 square feet of permanent impact and 820 square feet of temporary impact to Wetland RWB-04.

Portions of the Whittenton Electric Alternative along the Stoughton Line, would potentially impact rare species habitat within the Hockomock Swamp ACEC, which encompasses most of Priority and Estimated Habitat polygon (PH1392/EH59). Habitat potentially used by Blanding's turtle, eastern box turtle, blue spotted salamander, gypsywort and Hessel's hairstreak would be impacted within the Hockomock Swamp ACEC. An additional 11 state-listed species occur within the Hockomock Swamp polygon

(PH1392/EH59). Other rare species and their habitat may occur within the polygons or within the contiguous ACECs.

Mitigation for the barrier effect would likely be provided by:

- Reconstructing culverts to meet Commonwealth of Massachusetts Stream Crossing Standards[50]
- Installing between-the-ties crossing structures
- Installing wildlife crossing culvert

Indirect Impacts of the Whittenton Electric Alternative: Stoughton/Whittenton Rail Segment

The Whittenton Branch and the section of the Stoughton Line from Stoughton Station to Raynham Junction are inactive lines without tracks and ties for most of their lengths. Existing culverts carry streams beneath the abandoned railroad embankment and provide migratory habitat to wildlife species. In addition to the culverts, the right-of-way of the abandoned rail line itself provides suitable migratory habitat for rare species because there are no tracks and ties to prevent turtles and amphibians from moving across the right-of-way.

The right-of-way does not likely provide suitable nesting, breeding, and foraging habitat for rare species. However, as noted by the NHESP, much of the embankment has become reforested since the tracks were removed, and is likely to provide suitable feeding, sheltering, and overwintering habitat for blue-spotted salamanders and eastern box turtles. The GIS analysis did not show the loss of Atlantic white cedar swamp habitat; however, Atlantic white cedars were observed growing on the edges of the rail bed and may provide habitat for Hessel's hairstreak.

Documented nesting of spotted turtles within the abandoned rail line right-of-way indicates that portions of the right-of-way may also provide nesting habitat for Blanding's turtles and eastern box turtles, except for the area beneath the overhead powerlines south of Foundry Street. Nesting habitat of marginal quality is available within or adjacent to the rail right-of-way where the tree canopy is open enough for sunlight to incubate turtle eggs long enough for viable survival. Higher quality nesting habitat is present along the powerline right-of-way.

The reconstructed rail infrastructure, in locations where no tracks or ties currently exist, would prevent or impede the movement of Blanding's or eastern box turtles across the right-of-way. This habitat fragmentation could lead to the loss of genetic diversity and decrease in population size, potentially resulting in the local extirpation of some small populations.[51] Fragmentation of habitat for blue-spotted salamanders could potentially have similar results, although the rail would constitute a barrier to salamander movement for only 1,500 linear feet at the northern edge of the Hockomock Swamp population area and would not impede movement of salamanders for the remaining 7,000 linear feet of the trestle. No habitat fragmentation is anticipated for state-listed insect species which primarily occur along the active freight rail lines. Unlike the Stoughton Alternative, which crosses Pine Swamp between Raynham Junction and Weir Junction, the Whittenton Alternative would not utilize this segment and

[50] River and Stream Crossing Partnership. 2011. Massachusetts River and Stream Crossing Standards. The University of Massachusetts- Amherst (College of Natural Sciences), The Nature Conservancy, Massachusetts Division of Ecological Restoration- Riverways Program, American Rivers, and others. August 2004; revised March 1, 2006; revised March 1, 2011; corrected January 31, 2012.

[51] Steen, D.A. and J.P. Gibbs. 2004. Effects of roads on the structure of freshwater turtle populations. Cons. Biol. 18:1143-1148.

thus would avoid potential impacts to Hessel's hairstreak found within the Pine Swamp (PH1297/EH1077).

The indirect impacts to rare species associated with this alternative are the same as the ones described for the Stoughton Alternative, except that:

Loss of migratory routes (barrier effect) and increase in habitat fragmentation, because constructing of this track would be within undeveloped forested area. Within the Hockomock Swamp (PH1392/EH59), in areas north and south of the trestle, the total barrier effect would be approximately 3.6 miles. The barrier effect would be approximately 1.9 miles for Blanding's turtle between Depot Street and Foundry Street, approximately 0.4 mile for blue-spotted salamander between Foundry Street and the northern limit of the trestle, and approximately 0.9 mile for eastern box turtle between the southern limit of the trestle and Bridge Street. Within the Whittenton Branch (PH261/EH153) there is approximately 0.4 mile of additional barrier effect for the eastern box turtle. The barrier effect was estimated by calculating the length of the new track through the Priority and Estimated Habitat polygon. This is a conservative estimate of impact because it is unlikely that the entire length of the proposed new track would cross habitat suitable for migration. It does not account for the construction of culverts bridges or between-the-tie-crossings as part of the design that would improve the potential for wildlife passage and reduce fragmentation impacts.

Whittenton Diesel Alternative

No traction power facilities are proposed under the Whittenton Diesel Alternative. Therefore, the Whittenton Diesel Alternative, north of Weir Junction, involves approximately 1.9 acres less impact than the Whittenton Electric Alternative, which includes 0.8 acre of upland forest and 0.3 acre of upland shrub scrub within traction power station TPSS-1. All other rare species impacts are the same for the Whittenton Diesel Alternative as those associated with the Whittenton Electric Alternative.

Stations

This section describes the Priority and Estimated Habitats within the proposed station sites. None of the proposed station sites for any of the Build Alternatives are within mapped Priority Habitat. All the station sites are within partially or fully developed areas. Raynham Park is the only station where the platform would be within mapped Priority Habitat (PH1392); the rest of the station site and its parking lot would not be within the Priority Habitat polygon. The Raynham Park station would serve the Stoughton Alternatives (electric and diesel) and the Whittenton Alternatives (electric and diesel) (Figure 4.15-4-17). The Raynham Park station site does not provide potential habitat because it is mostly developed. Based on the habitat requirements of the species known to occur in the study area, it is unlikely that any of the identified rare species would be found on any of the station sites, except for the eastern box turtle.

Layover Facilities

Two preferred overnight layover facilities have been selected on the New Bedford Main Line and Fall River Secondary. Neither of the proposed layover facilities are located within Priority or Estimated Habitat polygons.

One midday rail layover facility is planned for the Boston area. This site is associated with the proposed expansion of South Station, which has independent utility of the South Coast Rail project and is not part of the South Coast Rail project. Any impacts associated with the expansion of South Station, including

midday layover facilities, would be addressed through the environmental review process associated with the proposed expansion of South Station. The proposed expansion of South Station is discussed in Chapter 3 as part of the No-Build Alternative.

4.15.3.4 Temporary Construction-Period Impacts

This section describes the range of potential temporary construction impacts to rare species caused by the construction of the South Coast Rail alternatives. It also describes a range of potential mitigation measures.

Temporary Impacts

Temporary impacts include short-term disturbances to rare species during construction that would cease once construction activities are complete. This may include, but is not limited to, the installation of erosion controls, the establishment of a work area, or the installation of a temporary structure at a stream crossing.

Potential short-term construction related impacts may include impairment of ground and surface water due to sedimentation in stormwater runoff or accidental spills; temporary loss of habitat, displacement of rare species due to physical disturbance and noise; and plant and animal injury or death from construction equipment and activities. In areas where the project would require construction in a wetland (resulting in the loss of wetland), the impact calculations include an area of temporary wetland impact extending 8 feet from the slope or retaining wall limit, to allow construction of footings or slope supports. These areas would be restored and revegetated following construction, with appropriate hydrology and plant species. This would result in a short-term loss of habitat available for state-listed species such as water-willow stem borer moth, pale green pinion moth, or coastal swamp amphipod.

Potential short-term construction related impacts may include impairment of ground and surface water due to sedimentation in stormwater runoff or accidental spills; temporary loss of habitat, displacement of rare species due to physical disturbance and noise; and plant and animal injury or death from construction equipment and activities.

The Stoughton Alternative would require reconstructing freight rail bridges across the Taunton River (within the New Bedford Main Line), potentially with temporary impacts to Atlantic sturgeon habitat. The National Marine Fisheries Service has noted that it is unlikely that this species occurs in the vicinity of the proposed project (see correspondence in Appendix 4.15-A).

Both the Stoughton and Whittenton Alternatives propose constructing a trestle along the Hockomock Swamp to avoid impacts to rare species and other wildlife. Constructing the trestle would require placement of hay bales and installing erosion controls along the limit of work which would result in a temporary barrier to rare salamanders and turtle species which currently use the abandoned right-of-way for migration. However, this barrier would only be a short-term temporary condition.

Mitigation for Construction-Period Impacts

Timing of construction may affect the extent of impacts to rare species. Disturbance of habitat during the breeding season is likely to have greater short-term or individual effects on reproductive success; however short-term effects are not likely to have long-term repercussions unless the species population is already unstable. To avoid potential short-term effects to breeding wildlife and rare species (e.g., turtles and salamanders) construction in areas where movement of rare species is a concern, including

the Hockomock Swamp, and Pine Swamp sections may be phased to reduce disruption during breeding season. Daily monitoring of the work areas by a qualified biologist/technician, on both sides of the fencing, would be conducted from early Spring through late Fall. In all cases, construction would be limited to normal daylight hours.

Construction impacts to rare species using or living within aquatic resources (e.g., mocha emerald, coastal swamp amphipod, and pale green pinion moth) would be mitigated through the appropriate use of erosion and sedimentation controls to minimize and eliminate sedimentation of wetlands and waterways. Erosion and sedimentation controls would be installed before construction begins, properly maintained through the construction period, and removed after disturbed areas have stabilized. Construction of bridges and culverts at stream crossings would follow Best Management Practices to avoid impacts to streams and rare species using them.

Detailed site-specific, species-specific mitigation measures would be developed in the permit process in consultation with NHESP. Some of the mitigation measures would include:

- Staking, entrenching siltation fencing at all limits of work within identified rare species habitat areas
- One-way turtle gates
- Daily monitoring of the work area by a qualified biologist/technician, on both sides of the fencing, from early Spring through late Fall; more specifically monitoring would be conducted in areas of rare species habitat as required by NHESP in the Conservation Management Plan (CMP)
- Removing any animals found within the work area
- Relocating any animals found along the drift fence (outside of the work area) to the opposite side of the corridor

Timing and Methods of Construction

Timing of construction may affect the extent of impacts to rare species. Disturbance of habitat during the breeding season is likely to have greater short term or individual effects on reproductive success; however short term effects are not likely to have long term repercussions unless the species population is already unstable. To avoid potential short term effects to breeding wildlife and rare species (e.g., turtles and salamanders), construction in areas where movement of rare species is a concern, including the Hockomock Swamp and Pine Swamp sections, may be phased to reduce disruption during breeding season. In all cases, construction would be limited to normal daylight hours.

Construction impacts to aquatic resources and associated rare species would be avoided and minimized by the appropriate use of erosion and sedimentation controls. These would be installed before construction begins, properly maintained, and removed after disturbed areas have stabilized.

To protect animals (primarily Blanding's turtle and eastern box turtle) during the construction process, the applicant would provide construction period protection and monitoring in all areas where work is proposed within mapped estimated habitat. Construction period monitoring would include:

- Inspecting siltation fencing at all limits of work within identified rare species habitat areas
- Inspecting the one way turtle gates
- Daily monitoring of the work area between Depot Street in Easton and Bridge Street in Raynham by a qualified biologist/technician, on both sides of the fencing, from early Spring through late Fall
- Removal/Relocating any animals found within the work area
- Relocating any animals found along the drift fence (outside of the work area) to the opposite side of the corridor

Post-construction Maintenance

Right-of-way maintenance is critical to the protection of the tracks and ties and to maintaining railroad safety. Right-of-way maintenance is done in accordance with an approved Vegetation Management Plan (VMP) and Yearly Operating Plan (YOP). To protect state-listed species along the project corridors, the applicant adheres to the approved VMP, as implemented with its YOPs, which restrict the use of herbicides in areas adjacent to wetlands or sensitive resources. Sensitive areas include wetlands within 10 feet of surface waters or wetlands where there is no herbicide use application, and include the entire Hockomock Swamp and Pine Swamp sections. Water resources and proposed stormwater management are described separately in the FEIS in Chapter 4.17, *Water Resources*.

4.15.3.5 Summary of Impacts by Alternative

A total of eight state-listed rare species have been recorded in areas adjacent to the project corridors. These include one salamander, two turtles, one crustacean, three moths and butterflies, and one dragonfly. Potential impacts to these species include habitat loss (primarily associated with filling wetlands) and habitat fragmentation, primarily due to constructing new track in areas that do not currently have track, out-of-service portions of the Stoughton Line, and Whittenton Branch. A detailed table of impacts for each of the alternatives is presented below.

No-Build (Enhanced Bus) Alternative

None of the proposed park-and-ride facilities are within Estimated and Priority Habitats. Therefore, none of the components of the No-Build Alternative are expected to impact rare species and/or their habitat.

Southern Triangle

The Southern Triangle portion of the project area includes the existing active Fall River Secondary and the New Bedford Main Line and is common to both railway alternatives (Stoughton and Whittenton). A detailed table of impacts for each of the alternatives is presented below and includes the Southern Triangle.

Stoughton Electric Alternative

The Stoughton Electric Alternative would adversely affect habitat of eight state-listed species (blue-spotted salamander, Blanding’s turtle, eastern box turtle, coastal swamp amphipod, mocha emerald dragonfly, Hessel’s hairstreak, pale green pinion moth, and water-willow stem borer), and result in a loss

of upland and wetland habitat loss of eight state-listed species (Table 4.15-10). Most of the impacts are expected along the track construction on out-of-service and abandoned portions of the Stoughton Line right-of-way between Stoughton Station and Dean Street. It is anticipated that within the Hockomock Swamp (PH1392/EH59), in areas north and south of the trestle, the Stoughton Line would interrupt migratory corridors for rare species. North of the trestle, the barrier effect would be approximately 1.9 miles and 0.4 mile within areas used by Blanding's turtle and blue-spotted salamander respectively; south of the trestle, the barrier effect would be approximately 0.9 mile within areas used by eastern box turtle (Table 4.15-10).

Table 4.15-10 Impacts by Species–Stoughton Electric Alternative

Species	Upland Habitat Loss (ac)	Wetland Habitat Loss (sf)	Wetland Temporary (sf)	Barrier Effect (length in miles)
Blanding's turtle (*Emydoidea blandingii*)	12.5	0	217	1.9
Blue Spotted salamander (*Ambystoma laterale*)	7.5	0	217	0.4
Hessel's hairstreak[2] *(Callophrys hesseli)*	NA[1]	18,578[4]	14,537	NA
Mocha emerald (*Somatochlora linearis*)	NA	9,474	6,406	NA
Coastal swamp amphipod (*Synurella chamberlaini*)	NA	11,691	9,758	NA
Water-willow stem borer moth (*Papaipema sulphurata*)	NA	11,691	9,758	NA
Pale green pinion moth (*Lithophane viridipalle*)	NA	11,691	9,758	NA
Gypsywort (*Lycopus rubellus*)	NA	NA	NA	NA
Long-leaved panic-grass (*Panicum rigidulum* ssp. *pubes cens*)	NA	NA	NA	NA
Eastern box turtle (*Terrapene carolina carolina*)	12.6[3]	NA	NA	0.9

1 Not applicable, no loss of suitable habitat.
2 Loss of 35 Atlantic white cedar trees.
3 Calculated by NHESP, including vegetated and unvegetated area.
4 Assumes all altered wetland contains suitable host species.

Raynham Park is the only station where part of the station (the platform) would be within mapped Priority Habitat (PH1392); the remainder of the station and its parking lot are outside of the Priority Habitat polygon. The platform impacts are within the limits of work of the Stoughton Line and are accounted for in the impacts associated with reconstruction of the track. The Raynham Park station site does not provide potential habitat because it is currently developed. None of the other station sites are within mapped Priority and Estimated Habitat.

Stoughton Diesel Alternative

The Stoughton Diesel Alternative would result in approximately 1.9 acres less impact than the electric alternative because no traction power facilities are proposed under the diesel alternative. All other rare

species impacts would be the same as those associated with the Stoughton Electric Alternative. These impacts include habitat loss for eight state-species and associated habitat fragmentation/barrier effect for three of these species (blue-spotted salamander, Blanding's turtle, and eastern box turtle).

Whittenton Electric Alternative

The Whittenton Electric Alternative would adversely affect habitat of eight state-listed species (blue-spotted salamander, Blanding's turtle, eastern box turtle, coastal swamp amphipod, mocha emerald dragonfly, Hessel's hairstreak, pale green pinion moth, and water-willow stem borer), and result in a loss of upland and wetland habitat loss of eight state-listed species (Table 4.15-11). Most of the impacts are expected along the track construction on out-of-service and abandoned portions of the Stoughton Line right-of-way between Stoughton Station and Dean Street. It is anticipated that within the Hockomock Swamp (PH1392/EH59), in areas north and south of the trestle, the Stoughton Line would interrupt migratory corridors for rare species. North of the trestle, the barrier effect would be approximately 1.9 miles and 0.4 mile within areas used by Blanding's turtle and blue-spotted salamander respectively; south of the trestle, the barrier effect would be approximately 1.3 miles within areas used by eastern box turtle (Table 4.15-11).

Most of the impacts are expected along the track construction on out-of-service and abandoned rights-of-way between Whittenton Junction and Raynham Junction (Whittenton Branch), and between Dean Street and Stoughton Station from Raynham Junction (portion of the Stoughton Line). It is anticipated that within the Hockomock Swamp (PH1392/EH59) and Whittenton Branch (PH261/EH153) the right-of-way would interrupt migratory corridors (3.6 miles of barrier effect) for rare species. North of the trestle, the barrier effect would be approximately 1.9 miles within areas used by Blanding's turtle and 0.4 mile within areas used by blue-spotted salamander. South of the trestle, the barrier effect 1.3 miles of additional barrier effect within areas used by eastern box turtle within the Whittenton Branch (Table 4.15-11).

Raynham Park is the only station where part of the station (the platform) would be within mapped Priority Habitat (PH1392); the remainder of the station and its parking lot are outside of the Priority Habitat polygon. The platform impacts are within the limits of work of the Stoughton Line and are accounted for in the impacts associated with reconstruction of the track. The Raynham Park station site does not provide potential habitat because it is currently developed. None of the other station sites are within mapped Priority and Estimated Habitat.

Table 4.15-11 Impacts by Species–Whittenton Electric Alternative

Species	Upland Habitat Loss (ac)	Wetland Habitat Loss (sf)	Wetland Temporary (sf)	Barrier Effect (length in miles)
Blanding's turtle (*Emydoidea blandingii*)	12.5	0	217	1.9
Blue Spotted salamander (*Ambystoma laterale*)	7.5	0	217	0.4
Hessel's hairstreak *(Callophrys hesseli)*	NA[1]	18,578	14,537	NA
Mocha emerald (*Somatochlora linearis*)	NA	9,474	6,406	NA
Coastal swamp amphipod (*Synurella chamberlaini*)	NA	11,691	9,758	NA
Water-willow stem borer moth (*Papaipema sulphurata*)	NA	11,691	9,758	NA
Pale green pinion moth (*Lithophane viridipalle*)	NA	11,691	9,758	NA
Gypsywort (Lycopus rubellus)	NA	NA	NA	NA
Long-leaved panic-grass (*Panicum rigidulum* ssp. *pubescens*)	NA	NA	NA	NA
Eastern box turtle (*Terrapene carolina carolina*)	13.8[2]	NA	NA	1.3[3]

1 Not applicable, no loss of suitable aquatic habitat
2 Calculated by NHESP, including vegetated and unvegetated area
3 Barrier effect equals 0.9 mile along north of Raynham Junction and 0.4 mile along the southern portion of the Whittenton Branch.

Whittenton Diesel Alternative

The Whittenton Diesel Alternative would result in approximately 1.9 acres less impact than the electric alternative because no traction power facilities are proposed under the diesel alternative. All other rare species impacts would be the same as those associated with the Whittenton Electric Alternative. These impacts include habitat loss for eight state-species and associated habitat fragmentation/barrier effect for three of these species (blue-spotted salamander, Blanding's turtle, and eastern box turtle).

Summary of Impacts

Each of the Build Alternatives could impact eight state-listed species, and would result in the loss of migratory route habitat because all Build Alternatives require construction of new rail lines where currently there are none (Table 4.15-12).

The Stoughton and Whittenton Alternatives would have potential impacts on suitable rare species habitat as seen in Table 4.15-10 and 4.15-11 for the diesel alternatives, respectively. The Stoughton and Whittenton Diesel Alternatives would each result in approximately 1.9 acres less impact than the electric alternative because no traction power facilities are proposed under the diesel alternative.

Long-leaved panic-grass is known to occur within the polygon that includes a wooded swamp area and the Cedar Swamp River (PH1158). The long leaved panic grass is associated with coastal plain pond shore communities, and occurs in moist open sandy habitats on the coastal plain. No suitable habitat has been identified in proximity to the rail right-of-way.

Table 4.15-12 Direct and Indirect Effects to Rare Species from the South Coast Rail Alternatives

	# of Priority Habitat (PH)	# of Rare Species Impacted[2]	Migratory Route (Barrier effect)
Stoughton Electric	5	8	3.2 miles
Stoughton Diesel	5	8	3.2 miles
Whittenton Electric	6	8	3.6 miles
Whittenton Diesel	6	8	3.6 miles
Stations	0	--	--
Layovers	0	--	--

The Stoughton and Whittenton Alternatives would result in the loss of migratory route habitat (barrier effect) of approximately 3.2 miles, and 3.6 miles, respectively.

4.15.3.6 Mitigation

This section describes the measures to avoid and minimize impacts to rare species and their habitat. It includes specific description of mitigation measures for each of the proposed alternatives.

Introduction

Measures to be developed in coordination with applicable regulatory agencies to avoid and minimize and mitigate rare species impacts within the project study area could include the following.

- Construct tunnels or other passages to facilitate movement across the railbed, with drift fencing.
- Construct a trestle within a section of the Hockomock Swamp as part of the Stoughton and Whittenton Alternatives.
- Construct new nesting or reproduction sites (e.g., for eastern box turtles).
- Supplement vegetation, particularly Atlantic white cedar populations.
- Conduct pre-construction studies to determine population size, distribution, or usage of the railbed to finalize mitigation measures.
- Develop protocols for protection of rare species during the construction process.
- Develop, in consultation with NHESP, mitigation measures that would be acceptable to provide a “net benefit to the local population” of each affected species. These measures may include:
    - Establish new habitat areas based on the state of the science
    - Acquisition of land or conservation restrictions that protect identified critical habitats that are at risk of loss or degradation

- Contribute to the mitigation bank for land protection of species such as the eastern box turtle

Avoidance

Habitat used by state-listed species is present in wetlands and uplands within the study area. Due to the close proximity of state-listed species habitat to the right-of-way, there are no feasible or practicable alternatives that would entirely avoid the loss of habitat. Avoidance of all impacts to rare species habitat would only be possible by implementing the No-Build Alternative (Enhanced Bus). The Build Alternatives would avoid impacts to rare species by:

- Locating all station sites and layover facilities outside of Priority Habitat, and not constructing maintenance roads along the project corridors.
- Keeping, when possible, the track construction and improvements within the existing footprint.
- Constructing a 8,500 foot trestle elevated through the Hockomock Swamp, from approximately 1,400 feet south of Foundry Street in Easton (near the SE Regional Vocational High School ball field) to approximately 1,400 feet north of the proposed Raynham Park station site (Figure 4.15-18). The trestle would be constructed using precast concrete beams, supported on concrete piles with a concrete pile cap. The span between piles would be approximately 30 feet, and the distance between the existing ground and the bottom of the beams would be 5 feet. At each end, the height of the trestle above the ground would decrease to approximately 2 feet above existing grade. To complete the return to ground level, approximately 900 feet of elevated track would be built between retaining walls at each end.
- The Whittenton Alternative would avoid all impacts to rare species habitat (i.e., Hessel's hairstreak) within Pine Swamp by following the Whittenton Branch, rather than the Stoughton Line south of Raynham Junction. However, this would increase impacts to eastern box turtle habitat.

The two proposed traction power substations (Easton and New Bedford) cannot be sited to avoid impact to state-listed species habitat. The only avoidance alternative would be the Stoughton Diesel Alternative. Traction power substations must be located in proximity to major power lines:

- Major power lines cross the New Bedford Main Line south of Samuel Barnett Boulevard. The presence of the powerlines dictates the location of the power substation, and there are no upland locations proximate to the proposed power substation that are not within mapped eastern box turtle habitat. The substation has been designed to avoid impacts to wetland habitats which may provide habitat to listed invertebrate species.
- A major power line crosses the Stoughton Line in the Hockomock Swamp, approximately 1.3 miles south of Foundry Street. The entire area both south and north of the power line is within mapped habitat for blue-spotted salamander and Blanding's turtle. Several alternative locations for this substation were evaluated prior to the publication of the DEIS/DEIR. Upland locations on the west side of the right-of-way were eliminated from further consideration as this land is Town of Easton Conservation Land, protected under

Article 97. In addition, any power substation on the west side would require constructing an access road parallel to the right-of-way, which would have increased impacts on rare species habitat and migration. Two alternative locations on the east side of the right-of-way, within land owned by the Southeast Regional Vocational-Technical School, were evaluated. Both locations are proximate to the right-of-way but within the school's athletic fields. These fields are used by the school athletic programs and by other Easton intermural sports programs. The applicant believes that it is not practicable to eliminate these youth athletic programs.

Minimization

Where construction and rehabilitation of a rail system would occur within or adjacent to rare species habitat, all practicable measures have been taken to minimize adverse impacts. The design refinement process that each of the proposed alternatives and associated stations have undergone since the ENF[52] was published has sequentially reduced impacts to rare species habitat. Measures to minimize impacts would continue through final design, including coordination with the regulatory agencies.

Some of the impact minimization efforts common to all alternatives include:

- Reducing the amount of rare species habitat loss by minimizing the width of work area within sections of the Fall River Secondary and most of the New Bedford Main Line by using single track instead of double track.
- Reducing the amount of rare species habitat loss by not constructing maintenance roads along the rail corridors.
- Replacing and enhancing structurally deficient culverts within the project corridor to allow movement through existing culverts to continue. Design measures would be identified to maintain existing hydrology between wetland systems.
- Further minimization efforts would be pursued during subsequent design phases, for example by using steeper slopes and reducing fill, or retaining walls.

Timing and Methods of Construction

Timing of construction affect the extent of impacts to rare species. Disturbance of habitat during the breeding season is likely to have greater short-term or individual effects on reproductive success; however short-term effects are not likely to have long-term repercussions unless the species population is already unstable. To avoid potential short-term effects to breeding wildlife and rare species (e.g., turtles and salamanders), construction in areas where movement of rare species is a concern, including Hockomock Swamp, and Pine Swamp sections may be phased to reduce disruption during breeding season. In all cases, construction would be limited to normal daylight hours.

Construction impacts to aquatic resources and associated rare species would be avoided and minimized by the appropriate use of erosion and sedimentation controls to minimize and eliminate sedimentation of wetlands and waterways. Erosion and sedimentation controls would be installed before construction begins, properly maintained, and removed after disturbed areas have stabilized. To protect animals during the construction process, the Applicant has indicated that it would provide construction period

[52] Executive Office of Transportation and Public Works, South Coast Rail Environmental Notification Form, November 2008.

protection and monitoring in all areas where work is proposed within mapped estimated habitat. Construction period monitoring would include:

- Staked, entrenched siltation fencing at all limits of work within identified rare species habitat areas
- Inspecting siltation fencing at all limits of work within identified rare species habitat areas
- Inspecting one-way turtle gates which would prevent animals that get onto roadways from being trapped between fences on both sides of the road
- Daily monitoring of the work area by a qualified biologist/technician, on both sides of the fencing, from early Spring through late Fall; more specifically monitoring would be conducted in areas of rare species habitat as required by NHESP in the CMP
- Removing any animals found within the work area
- Relocating any animals found along the drift fence (outside of the work area) to the opposite side of the corridor

Stoughton Alternative (Electric and Diesel)

The Stoughton Alternatives include a trestle through the Hockomock Swamp which would minimize loss of rare species habitat and barrier effects that would prevent turtle and salamander species from crossing the tracks. Wildlife passages (under-rail troughs) in the Pine Swamp may be considered as a mitigation measure.

Whittenton Alternative (Electric and Diesel)

As with the Stoughton Alternatives, the Whittenton Alternatives would minimize loss of rare species habitat and barrier effects by constructing the trestle through the Hockomock Swamp. In addition, this alternative would use wildlife passages along the Whittenton Branch to minimize impacts to the migration of eastern box turtles.

Specific Mitigation Measures

This section describes general mitigation measures common to all alternatives and mitigation measures specific for each of the proposed alternatives. It should be noted, however, that the mitigation measures described herein have been proposed by the applicant/proponents as conceptual mitigation options, and have not been officially endorsed by the USACE. Mitigation options could include, but are not limited to, those described here and could and may become part of a permitted project in the event that a permit is issued.

Common to All

Some of the general mitigation measures common to all alternatives would include:

- Constructing wildlife corridors/passages (e.g., enhanced stream culverts/oversized culverts, bridges, between tie crossings and under-rail troughs)
- Timing and methods of construction

- Post-construction maintenance
- Enhancing or replacing habitat by off-site habitat protection and preservation
- Funding research programs to benefit state-listed species

Provide Wildlife Corridors

Wildlife crossings are specially-designed culverts intended to allow small vertebrates to safely pass under the railroad. These have been conceptually designed in accordance to guidelines based on each species requirements. For example some culverts include skylights to allow natural light to illuminate the culvert; a natural substrate on the bottom of the culvert; and extended drift-fence wing walls to direct animals to the crossings. NHESP suggests that as the project design advances, site-specific information (topographic profile, elevation of track, groundwater) and conceptual designs at each recommended location should be developed and a variety of types of mitigation measures should be incorporated.

Chapter 4.14, *Biodiversity*, *Wildlife, and Vegetation*, provides an analysis of wildlife crossings and types of culverts and crossing structures evaluated as well as impacts to vernal pool habitat, general wildlife. Impacts to state-owned open space are addressed in Chapter 4.10, *Open Space*. Some of the proposed wildlife corridors include underpasses such as enhanced stream culverts, bridges and tunnels. Enhanced/oversized stream culverts are relatively simple concrete box culverts that pass underneath the ballast of the rail line. If there are no structural constraints, existing 5-foot culverts may be replaced with 8-foot wide culverts to provide additional wildlife crossing opportunities. Such enhanced culverts can be embedded to provide natural substrate within the culvert and to maintain hydraulic connectivity under a variety of flow conditions (Figure 4.15-19).

Enhanced stream culverts would be used at key locations to provide small vertebrates with riparian corridor connections. At selected bridges and culverts, the existing structure would be replaced with a structure that provided a shelf, a minimum of 16 inches wide, above the water elevation on each side of the stream channel. These would also be provided with extended drift fence wing-walls to direct animals to the crossing (Figure 4.15-20). Constructing rare species and/or wildlife underpasses and maintaining existing riparian corridors allows wildlife movement to continue. Many species, including large and small mammals, reptiles, and amphibians, will use areas under bridges to access breeding and feeding areas. Wildlife underpasses can maintain travel passages for rare species that may be unable to cross the tracks (such as salamanders and turtles). Drift fences would be installed to facilitate rare species/wildlife passage by directing movement to these underpasses. Additional fencing may be necessary to prevent larger turtles such as the Blanding's turtle from getting between the rails

Underpasses would also be constructed in the vicinity of vernal pools as well as in or near areas with landscape features that provide a connective function (such as shrubby areas that provide cover). The underpasses would be designed with a natural substrate and, where feasible, natural light to encourage some species to use culverts.[53] Topography presents a constraint to installing dry wildlife underpasses. Where the railroad is at-grade or in a cut, it is not practicable to install underpasses unless extensive excavation is done (potentially extending outside of the right-of-way) to create a 6-foot deep slope to the underpass. In such situations, under-rail troughs are preferable.

[53] Jackson, S.D. and C.R. Griffin. 1998. In Proceedings of the international conference on wildlife ecology and transportation (G.L. Evink, P. Garrett, D. Zeigler, and J. Berry, eds.). Report No. FL-ER-69-98. Tallahassee, FL.

Under rail troughs would be constructed within upland areas where no railroad infrastructure currently occurs, in areas where the reconstructed tracks could interrupt migratory patterns of blue-spotted salamander, eastern box turtle, or Blanding's turtle. This crossing structure was used successfully in another rail project in Massachusetts, the Greenbush Rail Line Project. This crossing structure was used successfully in another rail project in Massachusetts, the Greenbush Rail Line Project. This type of crossing structure has been previously reviewed and approved by regulatory agencies as a successful wildlife crossing structure. This crossing demonstrated to work well for spotted turtles, and may need refining and testing to appropriately size for larger turtles such as Blanding's turtle and eastern box turtles. The under-rail troughs include a liner between or below three consecutive rail ties that creates a 7- to 8-inch gap underneath the rails (Figure 4.15-20). Drift fences are installed on either side of the crossing to direct animals to the opening. These under-rail troughs could also be installed adjacent to grade crossings to allow turtles that wander onto the tracks to escape. NHESP recommended that the troughs be as deep as possible and lined with a natural material (not plastic), the wingwall guides should be a permanent material (not wood), and that a long-term monitoring and maintenance program established for continued function.

To mitigate for impacts to blue spotted salamander and Blanding's turtle, existing culverts would be enhanced along the segment between Depot Street and south of Foundry Street, and a new bridge that meets Commonwealth of Massachusetts stream crossing standards would be provided at Black Brook. NHESP requested that each of these structures be as wide as possible, preferably using bridges at all locations. If feasible, and there are no structural and/or grading constraints, additional wildlife crossings may be provided adjacent to some of the enhanced culverts. These additional crossings may take the form of dry culverts that can provide crossing opportunities for non-water dependent species. Mitigation for impacts to eastern box turtles would include constructing up to three under-rail troughs between the proposed Raynham Park Station site and Bridge Street to allow passage of wildlife between habitats separated by the tracks. Figures 4.15-21 and 4.15-22 shows potential locations for these passages. The final design and locations of these passages would be identified in consultation with NHESP; however, preliminary locations of these measures are identified in the Chapter 4.14, *Biodiversity, Wildlife, and Vegetation,* and on Figures 4.14-11a-e, 4.14-12a-d, 4.14-13a-c, 4.14-14a-b.

Post-Construction Maintenance

Right-of-way maintenance is critical to the protection of the tracks and ties and to maintaining railroad safety. Right-of-way maintenance is done in accordance with an approved VMP and YOPs. Adherence to an approved VMP, as implemented in conjunction with YOP, restricts the use of herbicides in areas adjacent to wetlands or sensitive resources. Sensitive areas include wetlands within 10 feet of surface waters or wetlands where there is no herbicide use application. Water resources and proposed stormwater management is described separately in Chapter 4.17, *Water Resources.*

Enhance and Replace Habitat

Opportunities to enhance and replace habitat for eastern box turtles, Blanding's turtles and blue-spotted salamanders are limited along the railroad right-of-way through Easton and Raynham. Adjacent areas are permanently protected open space, intact natural landscapes, or maintained golf courses. One mitigation opportunity in Easton would be to restore an abandoned gravel pit potentially used for turtle nesting. This could be planted with low, clump-forming native perennials interspersed with shrub species. This proposed nesting habitat could be maintained to provide sunny, well drained habitat preferred by nesting females. The area would need to be fenced and signed to exclude ATVs, which currently use the sand pit.

The applicant would enhance, restore, and replace wetlands and their respective functions and values impacted by the project corridors. Wetland mitigation areas adjacent to the project corridors would provide suitable habitat for several rare species and would be planted with water-willow and shrub species used by the pale green pinion moth.

Wetlands and their respective functions and values that are impacted by the Alternatives would need to be enhanced, restored, and replaced. Wetland mitigation areas adjacent to the Alternatives corridors could provide suitable habitat for several rare species. Wetland impacts and proposed mitigation are described separately in Chapter 4.16, *Wetlands*.

Native species such as Atlantic white cedars would be planted along the project alignment in areas where temporary wetland impacts would be restored, in Pine Swamp and the Assonet Cedar Swamp, to discourage invasion by weedy species in newly disturbed areas along the right-of-way. In addition, the applicant would investigate control methods that would remove or restrict invasive species that could spread into adjacent, high-value forested wetlands used by state-listed species. Chapter 4.14, *Biodiversity*, *Wildlife, and Vegetation*, provides more detailed information on the invasive species monitoring and control program.

Habitat Protection/Preservation

Long-term net benefits to rare species found along the project corridors would be provided by assuring permanent protection of the wetland and upland habitats of these species. Examples of habitat protection/preservation include:

- Acquiring land or conservation restrictions that protect identified critical habitats that are at risk of loss or degradation.

- Contributing to the mitigation bank for land protection of species such as the eastern box turtle.

NHESP, through its BioMap Program, has identified the Hockomock Swamp, Pine Swamp and other areas along the project corridors as “Core Habitat’, and has identified adjacent areas of “Supporting Natural Landscape.” Little of the Supporting Natural Landscape of these locations is protected. Portions of the Assonet Cedar Swamp are owned by the Massachusetts Audubon Society (although not protected by a Conservation Restriction). Areas adjacent to the Hockomock Swamp include suitable habitat for eastern box turtle and Blanding’s turtle, but are currently not protected.

Eastern Box Turtle (*Terrapene carolina carolina*) Habitat Bank—

The MESA regulations at 321 CMR 10.23(6)(b)(2), applicable to the eastern box turtle, state that:

> “The applicant shall provide off-site mitigation, or a combination of on-site and off-site mitigation subject to the Division's approval, that achieves the long-term Net Benefit standard in 321 CMR 10.23(1), as determined by the Division [of Wildlife]. Any off-site mitigation provided by the applicant in the form of a financial contribution will be used to fund habitat management or the protection of land or other appropriate mitigation within one or more conservation protection zones established in the conservation plan issued by the Division pursuant to 321 CMR 10.26. The amount of any such off-site mitigation payment will be determined by the Division based on a formula set forth in written guidance that, at a minimum, considers the area

of impact on the on-site habitat of the affected State-listed Species of Special Concern and the land values within one or more of the conservation protection zones."

The off-site mitigation proposed to achieve the long-term Net Benefit standard for impacts to eastern box turtle habitat consists of a financial contribution from the applicant to the NHESP's eastern box turtle habitat bank. The amount of such payment would be determined by the Division.

Once an appropriate mitigation ratio (the amount of land to be protected vs. the amount of habitat loss) is established by NHESP and the Corps, and an appropriate parcel is identified, the property would be acquired either through acquisition in fee or permanent conservation restriction.

Research Program

The majority of the species potentially affected by the rail reconstruction have also been studied at other locations in Massachusetts, and further investigations may not provide useful data that would contribute to the long-term health of these species. However, funding could be provided for scientific research on other state-listed species to enhance knowledge of their conservation biology and protection. Funding could also be provided for research programs within important Priority and Estimated Habitats impacted by the project corridors such as the Hockomock Swamp. The scope of these research programs focused on two of the species affected by the project could yield valuable information that would contribute to their protection and conservation.

Blanding's Turtle (*Emydoidea blandingii*)—Very little information is available about the Hockomock Swamp population of Blanding's turtle, other than anecdotal evidence and a few road-kills. The size, age structure, distribution, movements, and critical habitat areas (nesting, overwintering) have not been determined. A detailed study of this population would provide a net benefit to the species by helping to ensure that critical habitats are protected, and that effective measures to reduce road mortality are developed and installed.

Hessel's Hairstreak (*Callophrys hesseli*)—Very little information about the distribution and abundance of this species in Southeastern Massachusetts is available. The population may have been extirpated from the Hockomock Swamp since 2000 as a result of aerial spraying for mosquitos, and the abundance in Pine Swamp and the Assonet Cedar Swamp has not been recorded. The butterfly is not reported from the Acushnet Cedar Swamp despite the occurrence of suitable habitat. Studies to ascertain the distribution and abundance of this species within the Hockomock, Pine, Assonet, and Acushnet Cedar Swamps would inform the management plans for these properties, and could provide a net benefit by implementing mosquito control measures in sensitive areas that are not/are less lethal to Lepidoptera.

Stoughton Electric Alternative

For the Stoughton Alternative, mitigation would be focused on sections of the Stoughton Line within mapped habitat of blue-spotted salamander, Blanding's turtle, and eastern box turtle in areas outside of the limits of the proposed trestle. The Stoughton Line is an inactive line without tracks and ties for most of its length, and construction of a new rail would interrupt migratory corridors potentially used by these species. Impacts to these species would be avoided where the trestle is constructed through the Hockomock Swamp. Areas of mapped habitat for these species also exist between Depot Street and Foundry Street and between the proposed Raynham Park station site and Bridge Street, beyond the limits of the proposed trestle. For these segments, additional mitigation measures such as wildlife crossings would be required.

As a state threatened species, MESA regulations at 321 CMR 10.23(7) establish certain performance standards including mitigation ratios to achieve the long-term Net Benefit performance standard. These ratios are based on the amount of areal habitat impacted and the category of state-listed species. Accordingly, for Blanding's turtle, a 2:1 mitigation ratio is required. This species would have a loss of 12.5 acres of potential upland habitat, and approximately 1.9 miles of new track (with one new bridge, enhanced culverts and between-the-ties crossing structures) would create a barrier to movement in three segments. To provide a net benefit, the applicant has agreed to provide funding to protect 25 acres of land potentially used by the Hockomock Swamp population of Blanding's turtle, as well as to fund a study of this population that would determine the size and status of the population, identify nesting areas, identify important non-breeding areas, and identify locations where migratory pathways cross Route 138.

As a state species of special concern, MESA regulations at 321 CMR 10.23(7) establish certain performance standards including mitigation ratios to achieve the long-term Net Benefit performance standard. These ratios are based on the amount of areal habitat impacted and the category of state-listed species. Accordingly, for eastern box turtle, a 1.5:1 mitigation ratio is required. This species would experience a loss of 12.6 or 13.8 acres of potential habitat with the Stoughton or Whittenton Alternative, respectively (successional habitats along the railbed) and approximately 0.9 to 1.3 miles of new track (with between-the-ties crossing structures) would create a barrier to movement. To provide a net benefit, applicant has agreed to provide funding to the eastern box turtle mitigation bank equivalent to protecting 17 acres, or to protect 17 acres of habitat available to this population.

As a state species of special concern, MESA regulations at 321 CMR 10.23(7) establish certain performance standards including mitigation ratios to achieve the long-term Net Benefit performance standard. These ratios are based on the amount of areal habitat impacted and the category of state-listed species. Accordingly, for the blue-spotted salamander (State Special Concern), a 1.5:1 mitigation ratio is required. This species would have a loss of approximately 7.5 acres of upland habitat, and approximately 0.4 mile of new track (with enhanced culverts and a dry wildlife crossing) would create a barrier to movement in two locations. To provide a net benefit, the applicant has agreed to provide funding to protect approximately 11 acres of land potentially used by the Hockomock Swamp population of blue-spotted salamander.

The applicant anticipates that the land protection for the Blanding's turtle and blue-spotted salamander may overlap, and may be combined with wetlands preservation required for wetland mitigation

The re-establishment of commuter rail service along the rail bed would effectively eliminate the use of the corridor by ATVs, bicycles and pedestrians. Further measures could be taken to ensure that other ATV tracks throughout priority habitats are closed and extant vernal pools are protected from ATV use that negatively affects turtle and salamander habitat.

For the remainder of the species potentially impacted by this alternative, no mitigation has been proposed because:

- there would only be minor losses on the edge of the Priority Habitats and on the edge of the right-of-way;
- there would be no interruption of their migratory corridors; and
- impacts could be eliminated or reduced in final design.

In areas where no mitigation is proposed, there are culverts that would be replaced and are expected to benefit and provide improved crossing opportunities for rare and/or other wildlife species. For example, if there are no structural constraints, existing 5-foot culverts may be replaced with 8-foot wide culverts to provide additional wildlife crossing opportunities. Such enhanced culverts can be embedded to provide natural substrate within the culvert and to maintain hydraulic connectivity under a variety of flow conditions.

As previously suggested, habitat could be enhanced and restored for species dependent on particular habitat types. This could be accomplished by planting native species such as Atlantic white cedar.

Stoughton Diesel Alternative

Mitigation measures for impacts to rare species for the Stoughton Diesel Alternative are the same as the mitigation identified in the Stoughton Electric Alternative, because the impacts to rare species habitat would be the same.

Whittenton Electric Alternative

The mitigation measures proposed for the Whittenton Alternative would be similar to those proposed for the Stoughton Alternative. The major difference would be measures proposed for the eastern box turtle habitat found along the Whittenton Branch. Under-rail troughs would be constructed to connect upland areas within this Priority Habitat. Figure 4.15-30-31 shows the potential location for these passages. The final design and locations of these passages would be identified in consultation with NHESP.

Whittenton Diesel Alternative

Mitigation measures for impacts to rare species along the Whittenton Diesel Alternative are the same as the mitigation identified the Whittenton Electric Alternative, because the impacts to rare species habitat would be the same.

Some of the general mitigation measures common to all alternatives include:

- Constructing wildlife corridors/passages (e.g., enhanced stream culverts/oversized culverts, between-tie crossings and under-rail troughs)
- Timing and methods of construction
- Post-construction maintenance
- Enhancing and replacing habitat by off-site habitat protection and preservation
- Funding of research programs to benefit state-listed species

Specific mitigation measures (wildlife passages/corridors) would be provided and focused on project corridors where there would be loss of migratory route habitat. These areas include rare species Priority and Estimated Habitat found within out-of-service portions of the Stoughton Line and Whittenton Branch. No mitigation would be provided for the impacts for the Rapid Bus Alternative other than contribution to the eastern box turtle mitigation bank.

Table 4.15-13 provides a summary of the proposed structural mitigation measures for the rare species impacted by the South Coast Rail alternatives. Coordination with regulatory agencies has continued throughout the determination of the LEDPA, and would continue through selection of a final design, fine-grained analysis of actual habitat boundaries and impacts, and development of a detailed mitigation plan.

Table 4.15-13 Proposed Mitigation Measures for Rare Species

Element	Description	Quantity
Wildlife Crossings	Reconstruct culverts within Blanding's turtle (*Emydoidea blandingii*), blue-spotted salamander (*Ambystoma laterale*), eastern box turtle (*Terrapene carolina carolina*) habitat to enhance wildlife passage	To Be Determined (TBD)
	Construct between-the-ties crossing structures	TBD
	Construct below-grade wildlife crossing	TBD
Habitat Enhancement	Protect Easton sand pit	TBD
	Restore areas of temporary wetland impact in Pine Swamp and Acushnet Cedar Swamp with host plant species for state-listed Lepidoptera	TBD
Population Studies	Blanding's turtle (*Emydoidea blandingii*)	Hockomock Swamp population
	Hessel's hairstreak *(Callophrys hesseli)*	Southeastern Massachusetts
Habitat Protection[1]	Blanding's turtle (*Emydoidea blandingii*)	TBD (up to 25 acres)
	Blue-spotted salamander (*Ambystoma laterale*)	TBD (up to 11.25 acres)
Mitigation Bank (or habitat protection)	Eastern box turtle (Terrapene carolina carolina)	TBD (up to 17 acres)

4.15.4 **Regulatory Compliance of the Alternatives**

This section describes the federal and state regulations that protect rare species and, in some instances, their habitats, and describes how each alternative would comply.

4.15.4.1 Federal Endangered Species Act

The ESA of 1973, (16 USC 1531 *et seq.,* as amended),[54] authorizes the determination and listing of species as Endangered and Threatened and prohibits unauthorized taking, possession, sale, and transport of endangered species.

Section 7 of the Act[55] requires federal agencies to ensure that any action authorized, funded, or carried out by a federal agency is not likely to jeopardize the continued existence of listed species or to modify their critical habitat. The USFWS and NMFS administer the Act. Under Section 7, Federal agencies must

[54] Endangered Species Act of 1973, Section 7(16 USC 1531 *et seq.,* as amended), United States Fish and Wildlife Service.
[55] 6 U.S.C. 1536.

consult with the appropriate ESA agency when any action the agency carries out, funds, or authorizes (such as through a permit) may affect a listed endangered or threatened species.

The NMFS, a division of the U.S. Department of Commerce, is the federal agency responsible for protecting living marine resources including endangered marine life under the ESA. On December 4, 2008 a letter was submitted to the NMFS requesting information on any threatened and endangered fisheries resources located within the project area. NMFS response was received on January 12, 2009, with the determination that there are no federally endangered fisheries resources in the vicinity of the proposed project. Since the publication of the DEIS, the New York Bight Distinct Population Segment of Atlantic sturgeon was listed as endangered under the ESA by the NMFS on April 6, 2012.[56] Therefore, the Corps coordinated with NMFS to determine whether the Build Alternatives would affect this species. However, the NMFS stated in its May 13, 2013, response letter it is unlikely that any species listed under their jurisdiction will be exposed to any direct or indirect effects of the proposed South Coast Rail project, including the Atlantic sturgeon (see correspondence in Appendix 4.15-A). Therefore, further Section 7 consultation with NMFS is not necessary.

4.15.4.2 Massachusetts Endangered Species Act

Massachusetts enacted MESA in 1990. The Act (M.G.L. Chapter 131A) and its regulations (321 CMR 10.00) prohibit the "taking" of any state-listed rare plants and animals unless specifically permitted for scientific, educational, or propagation purposes, or where a Conservation and Management Permit is issued. "Take" includes protection of rare species habitat, and is defined as, "*in references to animals to harass, harm, pursue, hunt, shoot, hound, kill, trap, capture, collect, process, disrupt the nesting, breeding, feeding or migratory activity or attempt to engage in any such conduct, or to assist such conduct, and in reference to plants, means to collect, pick, kill, transplant, cut or process or attempt to engage or to assist in any such conduct. Disruption of nesting, breeding, feeding or migratory activity may result from, but is not limited to, the modification, degradation or destruction of Habitat*."

The regulations (321 CMR 10.05) state that "All State Agencies shall review, evaluate, and determine the impact on Endangered, Threatened and Special Concern species or their habitats… and use all practicable means and measures to avoid or minimize damage to such species or their habitats." State agencies are responsible for demonstrating to the Secretary that all practicable means and measures to protect rare species and their habitats have been incorporated into the project design. The Massachusetts Department of Fish and Wildlife's (DFW) Natural Heritage and Endangered Species Program (NHESP) is the agency responsible for ensuring compliance with MESA. If a proposed project would result in a "take," the project must obtain a Conservation and Management Permit from the NHESP.

With the exception of the No-Build Alternative, the two rail alternatives would result in a "take" of rare species and would require that NHESP issue a Conservation and Management Permit. As demonstrated in this chapter, the applicant has assessed practical alternatives that would avoid and minimize impacts to state-listed species, and could therefore comply with the regulatory performance standards. The amount of habitat impacted would ultimately be determined in the permitting process based on actual field delineation of rare species habitat, and would include a detailed analysis of actual habitat boundaries. Coordination with regulatory agencies has continued throughout the determination of the

[56] Federal Register: February 6, 2012 (Volume 77, Number 24, page 5880-5912), Endangered and Threatened Wildlife and Plants; Threatened and Endangered Status for Distinct Population Segments of Atlantic Sturgeon in the Northeast Region.

LEDPA, and would continue throughout subsequent phases including selection of a final design, and development of a detailed mitigation plan.

Avoidance and Minimization

MESA regulations at 321 CMR 10.05 state that "All State Agencies shall review, evaluate, and determine the impact on Endangered, Threatened and Special Concern species or their habitats and use all practicable means and measures to avoid or minimize damage to such species or their habitats." State agencies are responsible for demonstrating to the Secretary that all practicable means and measures to protect rare species and their habitats have been incorporated into the project design.

As documented in this chapter, the applicant has evaluated two route alternatives (Stoughton, and Whittenton) and determined neither of these alternatives would avoid impacts to rare species habitat. Potential impacts to state-listed species habitats have been minimized to the extent practicable, as described in this chapter. Impacts to state-listed species within the Hockomock Swamp have been minimized through the construction of a 1.8 mile elevated trestle, which would not create a barrier to the movement of reptiles or amphibians between wetland habitats. Table 4.15-13 describes the mitigation measures that would further minimize the effects of the alternatives by minimizing impacts during construction, enhancing migratory routes, and restoring areas of temporary alteration.

Alternatives

321 CMR 10.23(2)(a) requires that an applicant adequately assess alternatives to both temporary and permanent impacts to state-listed species. The applicant has evaluated two alternatives (Stoughton, and Whittenton) and determined that neither of these alternatives would avoid impacts to rare species habitat. The Stoughton and Whittenton Alternative meet the project purpose, and would have equivalent impact to state-listed species.

Insignificant Portion of the Local Population

321 CMR 10.23(2)(b) requires that a Conservation and Management Permit may only be issued where "an insignificant portion of the local population would be impacted by the Project or Activity".

As demonstrated in this chapter, the impacts to habitat of each of the state-listed species affected by the two alternatives would be a negligible portion of the total available habitat.

Net Benefit

321 CMR 10.23(2)(c) requires that a Conservation and Management Permit may only be issued where "the applicant agrees to carry out a conservation and management plan that provides a long-term Net Benefit to the conservation of the State-listed species".

The MESA regulations at 321 CMR 10.23(7) establish certain performance standards including mitigation ratios to achieve the long-term Net Benefit performance standard. These ratios are based on the amount of areal habitat impacted and the category of state-listed species.

- Endangered species require a mitigation ratio of 3:1 (three times the amount of affected habitat).
- Threatened species require a mitigation ratio of 2:1.

- Special Concern species require a mitigation ratio of 1.5:1.

The Director may approve an alternative mitigation approach that differs from these ratios where the alternative approach is appropriate, considering factors that include but are not limited to:

- The size and configuration of the habitat impact
- The threats to the affected state-listed species posed by uses or activities located adjacent to or in close proximity to the project
- The size, configuration and quality of the habitat proposed to be protected
- The population density of the affected state-listed species
- The habitat management and research needs associated with the affected species

The proposed project would provide a net benefit to the affected species by funding the protection of habitat at the appropriate ratio taking into consideration the loss of wetland and upland habitat as well as the length of the potential barrier to movement and the number and effectiveness of the proposed enhanced culverts and between-the-ties crossing structures.

For Blanding's turtle, a 2:1 mitigation ratio is required. This species would have a loss of 12.5 acres of potential upland habitat, and approximately 1.9 miles of new track (with new bridge, enhanced culverts and between-the-ties crossing structures) would create a barrier to movement in three segments. To provide a net benefit, the applicant has agreed to provide funding to protect 25 acres of land potentially used by the Hockomock Swamp population of Blanding's turtle, as well as to fund a study of this population that would determine the size and status of the population, identify nesting areas, identify important non-breeding areas, and identify locations where migratory pathways cross Route 138.

For eastern box turtle (State Special Concern), a 1.5:1 mitigation ratio is required. This species would experience a loss of 12.6 and 13.8 acres of potential habitat (successional habitats along the railbed) and approximately 0.9 to 1.3 miles of new track (with between-the-ties crossing structures) would create a barrier to movement by the Stoughton and Whittenton Alternatives, respectively. To provide a net benefit, the applicant has agreed to provide funding to the eastern box turtle mitigation bank equivalent to protecting 17 acres, or to protect 17 acres of habitat available to this population.

For the blue-spotted salamander (State Special Concern), a 1.5:1 mitigation ratio is required. This species would have a loss of approximately 7.5 acres of upland habitat, and approximately 0.4 mile of new track (with two enhanced culverts and a dry wildlife crossing) would create a barrier to movement in two locations. To provide a net benefit, the applicant has agreed to provide funding to protect approximately 11 acres of land potentially used by the Hockomock Swamp population of blue-spotted salamander.

The applicant anticipates that the land protection for the Blanding's turtle and blue-spotted salamander may overlap, and may be combined with wetlands preservation required for wetland mitigation.

4.15.4.3 Massachusetts Wetlands Protection Act

The Wetlands Protection Act Regulations (WPA [310 CMR 10.00 et seq.]) state that proposed projects that alter estimated rare wildlife habitat shall not be permitted to have any short-term or long-term

adverse effects on the habitat of the local population of that species. The regulations only apply to proposed projects that would alter the habitat of a rare animal species occurring in a wetland resource area for which an occurrence has been entered into the official NHESP database. Rare plants are not regulated under the WPA. The NHESP maintains an atlas of Estimated Habitat for state-listed rare species, which it updates every two years (most recently in 2008).

The NHESP has been consulted regularly by the Applicant throughout the course of the project and if work is proposed within Estimated Habitat, a Notice of Intent for a proposed project must be submitted to NHESP concurrent with the conservation commission submittal. All of the alternatives would likely result in a “take” of state-listed species and would result in both short- and long-term impacts to wetlands containing rare species habitat, and therefore would not comply with WPA performance standards. A variance under the WPA regulations, if granted, could be issued following NHESP’s approval of the CMP.

4.16 WETLANDS

4.16.1 Introduction

This chapter explains the jurisdictional authority and wetland regulatory procedures, and describes the methods and procedures used to delineate wetland resource areas along the South Coast Rail alternatives. This chapter also presents the methods used to quantify the direct impacts (both permanent and temporary) to all categories of wetland resource areas, and the methods used to assess secondary and/or indirect impacts to wetland functions and values. Finally, this chapter identifies the goals and opportunities for wetland mitigation, based on regulatory requirements and wetland impacts presented.

The results of an initial analysis of wetland impacts along the South Coast Rail project corridor were presented in the Draft EIS/EIR. The Secretary's Certificate on the DEIR/DEIS required further analysis or discussion on several aspects of wetland impacts in the FEIR. The Certificate stated that:

- "The FEIR should document any revisions to wetland boundaries and project-related impacts based on more detailed field delineations for the proposed Stoughton route, and boundaries as approved by local Conservation Commissions."
- "The FEIR should quantify temporary as well as permanent wetland impacts, for individual project components and cumulatively for the entire project (including stations and layover facilities)."
- "Direct and indirect wetlands impacts related to canopy clearance should be further evaluated in the FEIR."
- "Where there are differences in categorization under state and federal regulations, the FEIR should clarify and differentiate as appropriate. The FEIR should include a summary table with a breakdown of all wetland resource impacts (including BVW, Bank, Riverfront Area, and BLSF) for the entire project (rail, stations/layovers, roadway improvements, and other components) so that the individual resource impacts and the cumulative totals are summarized in one place."
- "The FEIR should include information on the location and volume of BLSF that will be impacted by the project."
- "The FEIR should quantify the total area of Riverfront Area impacted by the project, provide a breakdown of impacts at specific locations, describe how work proposed in riverfront will meet applicable performance standards."
- The FEIR should expand upon the analysis of wetlands functions and values in the DEIR/S to include a more detailed analysis for the proposed Stoughton rail. The FEIR should include narrative descriptions of wetlands functions and values of each wetland impacted directly and indirectly by the proposed project."

4.16.2 Resource Definition

The term "wetlands" means those areas that are inundated or saturated by surface or ground water at a frequency and duration sufficient to support, and that under normal circumstances do support, a prevalence of vegetation typically adapted for life in saturated soil conditions. Wetlands generally include swamps, marshes, bogs, and similar areas.[1] These areas are characterized by hydric soils, hydrophytic vegetation, and standing water or saturated soils. Wetlands provide benefits including flood storage, storm protection, ground water recharge, water filtration, and wildlife habitat. A full description of wetland resources, including their function and values, can be found in Section 4.16.2.1. Under MGL, Chapter 131, Section 40, "freshwater wetlands", are wet meadows, marshes, swamps, bogs, areas where groundwater, flowing or standing surface water or ice provide a significant part of the supporting substrate for a plant community for at least 5 months of the year; emergent and submergent plant communities in inland waters; that portion of any bank that touches any inland waters. There are several types of state regulated wetlands including: Bank, Bordering Vegetated Wetlands (BVW), Land under Waterbodies and Waterways (LUW), Land Subject to Flooding (LSF), and Riverfront Area (RA).

Wetland Resource Areas as defined in the Massachusetts WPA and its implementing regulations[2] that occur within the South Coast Rail project corridor include these inland and coastal resource areas:

- Bank;
- Bordering Vegetated Wetlands (BVW);
- Land Under Waterbodies and Waterways (LUW);
- Bordering Land Subject to Flooding (BLSF);
- Isolated Land Subject to Flooding (ILSF);
- Riverfront Area (RA);
- Land Subject to Coastal Storm Flowage (LSCSF); and
- Coastal Bank.

This section provides a brief description of the regulatory criteria defining each of these resources.

Bank—As defined in 310 CMR 10.54 (2)(a)&(c), a Bank is "... *the portion of the land surface that normally abuts and confines a waterbody.*" This land surface "... *may be partially or totally vegetated, or it may be comprised of exposed soil, gravel, or stone.*" "*The upper boundary of a Bank is delineated as the first observable break in the slope or the mean annual flood level, whichever is lower.*" Bank is present between a perennial river, lake or pond and the adjacent BVW or upland and within intermittent streams.

---

[1] Code of Federal Regulations (CFR) Title 33, Part 328.3(b), Definition of Waters of the United States.

[2] 310 CMR 10.00 et seq. http://www.lawlib.state.ma.us/source/mass/cmr/cmrtext/310CMR10.pdf, accessed June 1, 2012.

The regulations define a stream as "*a body of running water which moves within, into or out of an Area subject to protection of the Act… Such a body of running water that does not flow throughout the year (i.e. intermittent) is a stream except for that portion upgradient of all bogs, swamps, wet meadows and marshes.*" Accordingly, only those intermittent channels that convey water in response to a hydraulic gradient and those that are within or downgradient of BVW contain the resource area Bank.

Bordering Vegetated Wetlands (BVW)—As defined in 310 CMR 10.55(2)(a), "*Bordering Vegetated Wetlands are freshwater wetlands which border on creeks, rivers, streams, ponds and lakes.*" Bordering Vegetated Wetland (BVW) boundaries are defined in 310 CMR 10.55(2)(c) as "... *the line within which 50 percent or more of the vegetational community consists of wetland plants and saturated or inundated conditions exist.*"

Land Under Waterbodies and Waterways (LUW)—Land under Waterbodies and Waterways "*is the land beneath any creek, river, stream, pond or lake. Said land may be composed of organic muck or peat, fine sediments, rocks or bedrock. The boundary of Land Under Waterbodies and Waterways is the mean annual low water level*" [310 CMR 10.56 (2)(a)&(c)].

Vernal Pools—Vernal pools are not regulated under the WPA as a wetland resource area. Vernal pool habitats, as defined in 310 CMR 10.04, are "confined basin depressions, at least in most years, holding water for a minimum of two continuous months during the spring and/or summer," and must be within a regulated wetland resource area to be protected under the WPA. Vernal pool habitat includes the certified pool itself and all land within 100 feet of the pool that is also within a resource area. The presence of vernal pool habitat indicates that the wetland resource area provides important wildlife habitat. Vernal pools are described in Chapter 4.14, *Biodiversity, Wildlife and Vegetation*. Vernal pools discussed in this document are certified, potential, and field verified vernal pools located in wetlands within 750 feet of the right-of-way.

Bordering Land Subject to Flooding (BLSF)—"*Bordering Land Subject to Flooding is an area with low flat topography adjacent to and inundated by flood waters rising from creeks, rivers, streams, ponds, or lakes. It extends from the banks of these waterways and waterbodies; where a bordering vegetated wetland occurs, it extends from said wetland*" [310 CMR 10.57(2)(a)]. "*The boundary of Bordering Land Subject to Flooding is the estimated maximum lateral extent of flood water which will theoretically result from the statistical 100-year frequency storm… determined by reference to the most recently available flood profile data prepared for the community within which the work is proposed… under the Federal Emergency Mapping Agency…*" [310 CMR 10.57(2)(c)].

Isolated Land Subject to Flooding (ILSF)—"*Isolated Land Subject to Flooding is an isolated depression or closed basin without an inlet or outlet. It is an area which at least once a year confines standing water to a volume of one quarter acre-foot and an average depth of six inches*" [310 CMR 10.57(1)(b)].

Riverfront Area (RA)—Riverfront Area is "*the area of land between a [perennial] river's mean annual high-water line measured horizontally outward from the river and a parallel line located 200 feet away.*" [310 CMR 10.58 (2)(a)3]. Riverfront Area occurs at all locations where the right-of-way crosses a perennial watercourse, or is within 200 feet of a perennial watercourse. The regulatory presumptions regarding the intermittent or perennial nature state that "*if a river or stream is shown as intermittent or not shown on the current USGS map, or more recent map provided by the Department, an assertion that it is perennial must be supported by evidence…*" [310 CMR 10.58(2)(1)(a)].

Land Subject to Coastal Storm Flowage (LCSCF)—"*Land Subject to Coastal Storm Flowage means land subject to any inundation caused by coastal storms up to and including that caused by the 100-year storm, surge of record or storm of record, whichever is greater.*" [310 CMR 10.04].

Coastal Bank—"*Coastal Bank means the seaward face or side of any elevated landform, other than a coastal dune, which lies at the landward edge of a coastal beach, land subject to tidal action, or other wetland.*" [310 CMR 10.30].

Wetland resources in Massachusetts are regulated under local, state, and federal programs. The following section describes the regulatory context of the federal Clean Water Act (CWA), Massachusetts Wetlands Protection Act (the Act) and the local Bylaws.

4.16.3 Regulatory Context

The South Coast Rail project requires regulatory review under federal and state wetlands regulatory programs, as described below.

4.16.3.1 Section 404 of the Federal Clean Water Act

Section 404 of the Clean Water Act requires a Department of the Army (DA) permit for the discharge of dredged or fill material into waters of the United States,[3] including adjacent wetlands. The South Coast Rail project would require the issuance of an Individual Section 404 Permit (i.e., would not be eligible for the Massachusetts General Permit) as it would result in the loss of more than one acre of waters of the U.S. (including adjacent wetlands).

4.16.3.2 Section 10 of the Rivers and Harbors Act

Section 10 of the Rivers and Harbors Act of 1899 requires a DA permit for all work or structures (except bridges) in, under or over navigable waters of the United States.[4] In New England, for purposes of Section 10, navigable waters of the United States are those subject to the ebb and flow of the tide and a few of the major waterways used (presently or historically) to transport goods or services sold in interstate or foreign commerce. The Taunton River is a navigable waterway to the South Street East Bridge, in Taunton. It would be crossed by the Stoughton Alternative. In addition, the Mill River is navigable from its confluence with the Taunton River upstream to the Spring Street bridge in Taunton. It also would be crossed by the Stoughton Alternative.

Pursuant to a the General Bridge Act of 1946, 33 U.S.C. 525 et seq., the United States Coast Guard regulates bridges over waters regulated under Section 10. MassDOT would be required to obtain a bridge permit from the Coast Guard for reconstruction of bridges over the Taunton or Mill Rivers. The discharge of fill material associated with supporting structures such as bridge abutments would also be regulated by the Corps under the Corps' Section 404 authority noted above.

4.16.3.3 Section 401 of the Clean Water Act (Water Quality Certification)

Section 401 of the Clean Water Act (33 U.S.C. 1341) requires any applicant for a federal license or permit to conduct any activity that may result in a discharge of a pollutant into waters of the United States to

[3] Code of Federal Regulations (CFR) Title 33, Part 328.3(a), Definition of Waters of the United States.
[4] Code of Federal Regulations (CFR) Title 33, Part 329.4, Definition of Navigable Waters of the United States.

obtain a certification from the State in which the discharge originates or would originate, that the discharge will comply with the applicable effluent limitations and water quality standards.[5] In addition, the Massachusetts Department of Environmental Protection (DEP) is required to issue Water Quality Certifications for projects that result in discharge of fill to a wetland or waterbody, pursuant to the Massachusetts Clean Waters Act (M.G.L. c. 21 §§ 26 – 53). The South Coast Rail project would require issuance of an individual Section 401 Water Quality Certification because it would result in the loss of more than 5,000 square feet of wetlands subject to federal jurisdiction.

4.16.3.4 Coastal Zone Management

Section 307(c) of the Coastal Zone Management Act of 1972, as amended (16 U.S.C. 1456(c)), requires any non-federal applicant for a federal license or permit to conduct an activity affecting land or water uses in the state's coastal zone to furnish a certification that the proposed activity will comply with the state's coastal zone management program. Generally, no permit will be issued until the state has concurred with the non-federal applicant's certification. This provision becomes effective upon approval by the Secretary of Commerce of the state's coastal zone management program[6]. Accordingly, coastal zone consistency certification must be conferred by the Massachusetts Office of Coastal Zone Management before MassDOT can proceed with activities authorized by any DA permit.

The Coastal Zone Management (CZM) program has a series of policies that apply to activities within the Massachusetts Coastal Zone. Projects subject to federal consistency review (particularly activities subject to permitting under the Clean Water Act, Section 404) must be consistent with the CZM program policies. Under the Massachusetts CZM program all MEPA projects are reviewed for consistency with the management principles of CZM, which are intended as guidance for any activities proposed in the Coastal Zone. The overall goal of coastal zone management is to protect coastal resources from contamination or degradation, prevent the creation of coastal hazards, and maximize the public use and benefit of coastal areas.

Additional information regarding compliance with the Coastal Zone Management program can be found in Chapter 4.18, *Coastal Zone Consistency and Chapter 91*.

Table 4.16-1 identifies the municipalities in the study area that are at least partially within the Massachusetts Coastal Zone.

Table 4.16-1 Study Area Communities Within the Coastal Zone

Municipalities Within Coastal Zone		
Acushnet	Fall River	Rehoboth
Berkley	Freetown	Somerset
Dartmouth	Mattapoisett	Swansea
Dighton	New Bedford	Westport
Fairhaven		

[5] Code of Federal Regulations (CFR) Title 33, Part 320.3(a), General Regulatory Policies.
[6] Code of Federal Regulations (CFR) Title 33, Part 320.3(b), General Regulatory Policies.

4.16.3.5 Massachusetts Wetlands Protection Act

The Massachusetts Wetlands Protection Act (WPA) regulations establish performance standards for work proposed within each of the resource areas, and require review of any work proposed within 100 feet of a wetland resource to determine if that work will result in the alteration of wetland resources. "Alteration" is defined to "include a change in vegetation, hydrology, or water quality of the wetland."

Outstanding Resource Waters

Massachusetts regulations designate certain areas as Outstanding Resource Waters (ORWs), "as determined by their outstanding socioeconomic, recreational, ecological and/or aesthetic values." ORWs in Massachusetts include public drinking water supplies, as well as tributaries to these supplies. Vernal pools are also designated as ORWs.

4.16.3.6 Local Wetland Bylaws and Ordinances

Several communities along the right-of-way corridors enforce local wetlands protection bylaws that may further regulate many of these resource areas. The United States Army Corps of Engineers (Corps) as a federal agency is not subject to local laws and regulations. As a state agency, MassDOT is exempt from local bylaws and local bylaws are not addressed in this document.

4.16.4 Regulatory Procedures and Definitions

4.16.4.1 Wetland Identification During the DEIS/DEIR

This section describes the initial efforts to document existing wetlands adjacent to the South Coast Rail alternatives presented in the DEIS/DEIR.

Methodology

Each alternative corridor was assessed for the presence of wetland resources within and adjacent to the right-of-way. In addition to the right-of-way, each of the proposed station sites and layover facilities was evaluated for the presence of wetlands on-site and on abutting properties. Three sources of information were used to determine the approximate limits of existing wetlands, their cover type and their connectivity to larger wetland systems. The sources of information included (1) existing information available from previous Orders of Resource Area Delineation (ORADs) that were issued in 2000-2002, (2) GIS mapping using data available from MassGIS[7], and (3) field verification in selected locations.

The Information from existing reports had not been field reviewed by the Corps, was more than three years old, and was not available for the Attleboro or Rapid Bus alternatives. Therefore, the approximate size and cover type of each wetland used in the DEIS/DEIR impacts analysis for all alternatives was created from Geographic Information Systems (GIS) mapping that was further modified through review of features visible on aerial photographs and topographic maps. In addition, aerial photographs in conjunction with field verification were used for the proposed station sites, the Attleboro Bypass, and the Whittenton Secondary.

[7] MassGIS Data - DEP Wetlands (1:12,000).

During scoping, the U.S. Army Corps of Engineers' New England District used the Highway Methodology Workbook Supplement[8] to evaluate existing wetlands and their functions and values. This approach was specifically recommended by USEPA, and was adopted by the Corps as an initial screening tool for purposes of evaluating impacts to wetlands likely to result from the alternatives under consideration by MassDOT. During early stages of the Highway Methodology[9] a large number of alternatives may be under consideration and only limited field observations are made in order to screen out those that are obviously either not practicable or are clearly not the Least Environmentally Practicable Alternative (LEDPA). At this stage existing information is typically very general and wetland boundaries are defined as a composite of National Wetland Inventory as devised by Cowardin et al.,[10] and Natural Resource Conservation Service maps. Cover types according to the Cowardin system and key wetland functions and values can be derived from the literature, limited field investigations, or public input. Additional field work sufficient to satisfy the determination of the LEDPA is usually required. Wetland evaluation forms are generally completed and the data is presented graphically. After the LEDPA is determined, it is subjected to a three parameter delineation of the affected wetlands using the required Corps method and data sheets.

Existing Information

Extensive existing information for wetland resources along the right-of-way for the Stoughton Alternative and the Southern Triangle was available from information filed in the 1999 Draft EIR, the 2002 Final EIR, and Abbreviated Notices of Resource Area Delineation (ANRADs) filed with the local conservation commissions in the study area.

In the 2002 Final EIR, all Bordering Vegetated Wetlands (BVW) and Bank within or adjacent to the right-of-way were delineated for The Stoughton Alternative. The Conservation Commissions of Canton, Stoughton, Easton, Raynham, and Taunton reviewed ANRADs submitted for the wetland resource areas that occur within their communities. Canton, Stoughton, Raynham, and Taunton approved the limit of resource areas defined in the ANRADs submitted to the Commissions, while the Easton ANRAD was reviewed and approved by the Department of Environmental Protection (DEP) Southeast Regional office. ANRADs were also submitted to the remaining towns and cities for The Stoughton Alternative; however the review was not completed. The information available through these past filings includes wetland cover type, approximate size, and field-delineated wetland boundaries. Wetland boundaries were flagged between 1997 and 2001 and represent the limit of wetland resources that were present at that time. This information combined with the modified GIS layer (described below) provided the starting point for the wetland information presented in the figures included in the DEIS/DEIR.

GIS Mapping

The MassGIS DEP Wetlands layer, last updated in April 2007, provided an underlying data set for defining wetland resources for each of the analytical approaches. This layer provided approximate location, general vegetation cover type, and size of wetland resources, including hydrologic connections

[10] Cowardin, L.M., V. Carter V., F.C. Golet, E.T. LaRoe. 1979. Classification of Wetlands and Deepwater Habitats of the United States. U.S. Fish and Wildlife Service Report No. FWS/OBS/-79/31.Washington, D.C.

and stream characteristics. Information contained in this layer was interpreted from 1:12,000 scale, stereo color-infrared (CIR) photography by staff at the University of Massachusetts (UMASS), Amherst.

Wetland resources along the right-of-way were initially identified using this data layer. Upon closer examination of the individual wetland polygons, it became apparent through visible features shown on aerial photographs that portions of the individual wetland polygons were not accurate and required modification. Once the wetlands layer was brought into the ESRI ArcMap 9.2 and 9.3 GIS program, aerial photographs obtained through Microsoft Livesearch® were used in conjunction with USGS topographic maps to identify existing polygons that required modification. Further correction and assessment of wetland boundaries was made using the Microsoft Livesearch® bird's-eye view tool, which provides oblique aerial images at varying degrees of resolution. Clear continuation of cover types observed through aerial photographs, instances of open water, visible depressions, and elevation lines were used as a basis to modify polygons to create a more accurate wetlands layer. To the extent possible, cover types were also verified during this process.

Each right-of-way was evaluated for the presence of BLSF through GIS mapping. Federal Emergency Management Agency (FEMA) floodplain maps were used in conjunction with the modified DEP Wetland layers to determine where the 100-year floodplain extended past the boundary of Bank and BVW. BLSF was assumed to occur in such instances.

Riverfront Area was evaluated where the USGS 7.5 Minute map showed a perennial stream crossing the right-of-way. Bank could not be accurately delineated at this scale of resolution.

Due to the limitations of this methodology, no ILSF or non-state federal wetlands were identified using this approach. Wetlands within or adjacent to the right-of-way for the Stoughton and Whittenton Alternatives (Electric and Diesel) were delineated in accordance with the Corps of Engineers Wetlands Delineation Manual, as updated. However, wetland inspections were not able to be performed along the Attleboro Secondary Line, an active rail line, extends from Whittenton Junction to Weir Junction. The majority of this section of track (approximately 1.7 miles) is a densely developed area between Danforth Street and Weir Junction. The remaining stretch of tracks between Whittenton Junction and Danforth Street (approximately 0.7 mile) was assessed using available information.

Mapped vernal pools consist of certified vernal pools and potential vernal pools as identified in the 2010 Natural Heritage and Endangered Species Program (NHESP) Natural Heritage Atlas as well as vernal pools that were field verified for the South Coast Rail project. Additional information on vernal pools can be found in Chapter 4.14, *Biodiversity, Wildlife and Vegetation*.

A review of the 2010 Edition of the Massachusetts NHESP Natural Heritage Atlas was performed to identify areas where the South Coast Rail alternatives cross Estimated Habitats of Rare Wildlife. The Estimated Habitats of Rare Wildlife polygons are based on occurrences of rare wetland wildlife observed within the last 25 years and documented in the NHESP database. They do not include those areas delineated for rare plants or for rare wildlife with strictly upland habitat requirements. Wetland resources within these Estimated Habitat polygons were identified using NHESP GIS data available through MassGIS. Additional information on Estimated Habitat of Rare Wildlife can be found in Chapter 4.15, *Threatened and Endangered Species*.

Field Verification

Field verification was used in areas where aerial photographs and topographic maps provided inconclusive results. This approach was also used at station sites where wetland boundaries were required for site and station building design. Field verification was also required along the Whittenton Secondary segment of the Stoughton Line (Whittenton Alternative) because examination of aerial photographs in this area did not provide sufficient information for wetland polygon modification.

Field verification of these areas was performed using a Tablet PC GPS system that displayed aerial photographs and the MassGIS DEP Wetlands layer. Approximate wetland boundaries were walked at each of the sites and either sketched onto a plan or marked using GPS. The DEP Wetland polygons were then modified using the information collected in the field. Cover types were also verified in the field and modified as needed. Preliminary assessment of cover type was made using the classification systems presented in the MassGIS data. Cowardin classifications of wetland areas were made based on these cover types. This process was performed at station sites where prior field delineated information was not available.

Ditches along the right-of-way required a different approach in interpreting their presence and how to properly regulate them. Ditches can be regulated as an isolated wetland, ILSF, BVW, or Bank depending on their characteristics and whether or not they connect two or more waters of the United States. It should be noted that ditches excavated on dry land (i.e., in uplands) solely for the purpose of draining such infrastructure as highways and railroad lines are generally not considered waters of the United States. Ditches along alternatives for which detailed information existed were described as such. Ditches were difficult to accurately represent for the alternatives which only used GIS interpretation, as the aerial photography did not possess sufficient detail. Ditches along the Stoughton Alternative and the Southern Triangle rail rights-of-way were field verified and brought into the DEP Wetlands layer as they were observed in the field.

4.16.4.2 Federal Delineation Procedures

A more refined identification of wetland resource areas was conducting following publication of the DEIS/DEIR. This section describes both federal and state procedures for delineating wetland resource areas, and defines those resource areas.

Wetland resource areas in the project right-of-way are federally regulated under Section 404 of the Clean Water Act.[11]

The methods in the 1987 Corps of Engineers Wetland Delineation Manual (1987 Corps Manual) require that three criteria ("diagnostic environmental characteristics") be met for an area to be classified as a jurisdictional wetland: dominance of hydrophytic vegetation, presence of hydric soils, and evidence of wetland hydrology.

In 2009, the USACE issued Regional Supplements to the 1987 Corps Manual; final versions of the supplements were issued in 2012. Massachusetts falls into the Northcentral and Northeast Region.[12] The

[11] 33 USC §1344 – Permits for Dredged or Fill Material. http://www.law.cornell.edu/uscode/text/33/1344, accessed May 30, 2012.

[12] U.S. Army Corps of Engineers. 2012. *Regional Supplement to the Corps of Engineers Wetland Delineation Manual: Northcentral and Northeast Region (ERDC/EL TR-12-1)*. Vicksburg Mississippi, U.S. Army Engineer Research and Development Center.

purpose of the Regional Supplement is to “address regional wetland characteristics and improve the accuracy and efficiency of wetland-delineation procedures.” The Regional Supplement provides a number of revised and refined defining characteristics and methods to be used to identify wetlands in the field, in order to increase the regional sensitivity of wetland delineation in the Northcentral and Northeast Region.

Although the Regional Supplement states that the determination of jurisdiction for a given wetland is still subject to Section 404 of the Clean Water Act, it also provides information to replace sections of the 1987 Corps Manual, and states: “*Where differences in the two documents occur, this Regional Supplement takes precedence over the Corps Manual for applications in the Northcentral and Northeast Region*.”

Hydrophytic Vegetation

According to the 1987 Corps Manual, the prevalent vegetation in jurisdictional wetlands consists of macrophytes that are typically adapted to areas having the hydrologic and soil conditions that are described in the Manual’s definition of wetlands. Hydrophytic species, due to morphological, physiological, and/or reproductive adaptations, have the ability to grow, effectively compete, reproduce, and/or persist in anaerobic soil conditions. Plant species have been compiled in a list[13] and are given a wetland indicator status to denote the hydrologic regime in which they are most often found. The indicator status can be Obligate (OBL), Facultative Wet (FACW), Facultative (FAC), Facultative Upland (FACU), or Upland (UPL). The use of (+) and (–) modifiers further refine those categories, with (+) designating a preference for a wetter regime and (-) a drier regime. According to the 1987 Corps Manual, a plant with a status of FAC or wetter is considered to be a wetland plant, while a plant with a status of FAC-or drier is considered to be a non-wetland plant. The 1987 Corps Manual makes note of the fact that some plant species have broad ecological tolerances and occur in both wetlands and non-wetlands.

The 2012 Northcentral/Northeast Regional Supplement provides guidance on vegetation sampling and analysis to supplement the 1987 Corps Manual, including more precise definitions of plant strata and field techniques than are found in the 1987 Corps Manual. Of particular note, the Regional Supplement alters the usage of indicator status for a given plant species by removing the usage of (+) and (–) modifiers. Therefore, any plant with an indicator status of FAC-, which would have previously been considered a non-wetland plant, is now grouped with all other plants with an indicator status of FAC, making these wetland plants. As of June 1, 2012, the National Wetland Plant list has been updated to reflect these changes.[14]

Hydric Soils

The 1987 Corps Manual defines a hydric soil as “*a soil that is saturated, flooded, or ponded long enough during the growing season to develop anaerobic conditions that favor the growth and regeneration of hydrophytic vegetation.*” The 1987 Corps Manual describes several characteristics and features that are

---

[13] Reed, P. B., Jr. 1988. *National list of plant species that occur in wetlands: 1988 national summary.* Biological Report 88(24). Washington, DC: U.S. Fish and Wildlife Service.

[14] Lichvar, R.W. and J.T. Kartesz. 2009. North American Digital Flora: National Wetland Plant List, version 2.4.0. U.S. Army Corps of Engineers, Engineer Research and Development Center, Cold Regions Research and Engineering Laboratory, Hanover, NH, and BONAP, Chapel Hill, NC. https://wetland_plants.usace.army.mil, accessed June 29, 2012.

used to identify soils as hydric, such as the presence of layers of organic material, reducing (low oxygen) soil conditions, and soil colors that result from prolonged saturation and/or inundation.

The Regional Supplement presents indicators that are designed to help identify hydric soils in the Northcentral and Northeast Region, along with accompanying photographs and identifying criteria. The Regional Supplement does not change the core definition of a hydric soil in the 1987 Corps Manual, and notes that: “Indicators are not intended to replace or relieve the requirements contained in the definition of a hydric soil. Therefore, a soil that meets the definition of a hydric soil is hydric whether or not it exhibits indicators.”

Hydrology

The 1987 Corps Manual establishes criteria to identify wetland hydrology: “*Areas with evident characteristics of wetland hydrology are those where the presence of water has an overriding influence on characteristics of vegetation and soils due to anaerobic and reducing conditions, respectively. Such characteristics are usually present in areas that are inundated or have soils that are saturated to the surface for sufficient duration to develop hydric soils and support vegetation typically adapted for life in periodically anaerobic soil conditions.*” The 1987 Corps Manual provides a number of identifying factors that are used in the field to determine the hydrology of an area, including direct observation of inundation, soil saturation, and evident drainage patterns.

The Regional Supplement presents indicators that are designed to help identify wetland hydrology in the Northcentral and Northeast, along with accompanying photographs and identifying criteria. According to the Regional Supplement, wetland hydrology indicators “provide evidence that the site has a *continuing* wetland hydrologic regime and that hydric soils and hydrophytic vegetation are not relicts of a past hydrologic regime.”

Guidance Memorandum

In 2007, the USACE and the USEPA issued a joint guidance memorandum on Clean Water Act Jurisdiction following the U.S. Supreme Court’s decision in *Rapanos v. United States* & *Carabell v. United States.*[15] The memorandum was revised after public comment and the final document was issued on December 2, 2008. The memorandum provided guidance to USEPA regions and Corps districts, particularly in regards to situations in which the agencies should apply the “significant nexus” determination to determine whether or not to take jurisdiction over an area.

In accordance with the guidance document, all of the wetlands and waterways identified and delineated for the South Coast Rail project are considered jurisdictional because they are either:

- Traditional navigable waters;
- Wetlands adjacent to traditional navigable waters
- Non-navigable tributaries of traditional navigable waters that are relatively permanent where the tributaries typically flow year-round or have continuous flow at least seasonally (e.g., typically 3 months); or

[15] U.S. Army Corps of Engineers (USACE) and U.S. Environmental Protection Agency, Clean Water Act Jurisdiction Following the U.S. Supreme Court’s Decision in Rapanos v. United States &Carabell v. United States, June 6, 2007, revised December 2, 2008.

- Wetlands that directly abut such tributaries.

Additional guidance concerning Corps jurisdiction is found in the Corps' Regulatory Guidance Letter 08-02 (Jurisdictional Determinations).[16] RGL 08-02 stipulates that an applicant may elect to use a preliminary jurisdictional determination to voluntarily waive or set aside questions of jurisdiction over a particular site or resource area. A landowner, permit applicant, or other "affected party" may elect to use a preliminary JD even where initial indications are that the water bodies or wetlands on a site may not be jurisdictional. Although some small wetlands within or along the right-of-way are "isolated" – i.e., they do not directly touch or abut any traditional navigable waters (or tributaries thereto) – at this time MassDOT is not asserting that these wetlands do not have a significant nexus to a traditional navigable water. Therefore MassDOT has voluntarily elected to assume that these wetlands are jurisdictional waters of the United States. However, any areas characterized as "swales or erosional features," which do not flow through or out of another jurisdictional resource area, or which are "excavated wholly in and draining only uplands and that do not carry a relatively permanent flow of water," are not jurisdictional according to the joint guidance memorandum, and have not been delineated as wetland resource areas. These include former or current railroad drainage ditches excavated in uplands.

The Corps prepared a Preliminary Jurisdictional Determination for the proposed Stoughton and Whittenton railroad rights-of-way on February 4, 2013. A total of 73.0 acres of waters, including 70.2 acres of wetlands and 2.8 acres of other waters, were determined to be present within the existing railroad rights-of-way, plus at proposed railroad station locations. For purposes of this preliminary jurisdictional determination, any waterway that was found to contain wetlands in part is considered to be wetlands (and therefore a "special aquatic site" as defined by USEPA regulations at 40 CFR 230, Subpart E), in entirety. The preliminary jurisdictional determination was accepted and signed by MassDOT on February 19, 2013 and is attached to this FEIS as Appendix 4.16-A.

4.16.4.3 State Delineation Procedures

Wetland resource areas in the South Coast Rail project right-of-way are state regulated under the WPA.[17] Delineation of BVW resource areas under Massachusetts wetland regulations are addressed in a 1995 state handbook *Delineating Bordering Vegetated Wetlands Under the Massachusetts Wetlands Protection Act: A Handbook* (1995 State Handbook).[18] The 1995 State Handbook identifies wetlands as: "areas where groundwater is at or near the surface, or where surface water frequently collects for a significant part of the growing season, and where a significant part of the vegetative community is made up of plants adapted to life in saturated soil." The 1995 State Handbook also identifies the two characteristics that determine state jurisdictional wetlands: "Hydrology (water) and vegetation (plants) are the two characteristics that define freshwater wetlands protected by the Act." These characteristics are discussed below.

[18] Jackson, S. 1995. *Delineating Bordering Vegetated Wetlands under the Massachusetts Wetlands Protection Act: A Handbook*. Massachusetts Department of Environmental Protection, Division of Wetlands and Waterways.

Vegetation

The 1995 State Handbook refers to the same list of plants and their wetland indicator status as the 1987 Corps Manual, noting that plants with a rating of FAC or wetter are considered wetland indicator plants. The 1995 State Handbook also references plant species listed in the WPA and plants that exhibit morphological or physiological adaptations to life in saturated or inundated conditions as wetland indicator plants.

Hydrology

The 1995 State Handbook includes hydric soil characteristics as an indicator of wetland hydrology. Therefore, if an area has a dominance of wetland vegetation and exhibits hydric soil characteristics, it is considered to be a wetland. Areas that do not exhibit hydric soil characteristics, but that have a dominance of wetland vegetation as well as other indicators of hydrology, may also be considered wetlands. These other indicators of hydrology include evidence of surface water, evidence of soil saturation, and morphological plant adaptations.

Comparison of Federal and State Delineation Methods

The 1987 Corps Manual names three distinct criteria of hydrophytic vegetation, hydric soils, and hydrology that must all be satisfied for an area to be considered a wetland resource area. The 1995 State Manual names only the two criteria of vegetation and hydrology, and includes hydric soils as a sign of hydrology. In addition, small isolated wetlands are not considered jurisdictional under state delineation methods, while these areas may be jurisdictional under federal delineation methods if they have a “significant nexus” to a bordering vegetated wetland.[19] MassDOT has assumed that all isolated wetlands along the South Coast Rail project corridor are federally jurisdictional.

Vegetated wetland resource areas along the Stoughton alternative and Whittenton Branch were delineated with respect to both methodologies. Any areas that exhibited hydrophytic vegetation, hydric soils, and hydrology were flagged as wetland resource areas under both state and federal jurisdiction. Small isolated areas were also flagged and were noted as being under federal jurisdiction only.

4.16.5 Delineation Methods and Procedures

In order to identify and delineate the jurisdictional wetland resource areas within the South Coast Rail project corridor, field surveys were conducted along the entire length of the right-of-way. This effort involved field work in all ten municipalities along the length of the project corridor.

The initial wetland review work done for the 2009 DEIS/DEIR provided a body of knowledge and a series of figures on which to base the field work. Wetland resource areas along the Stoughton Alternative were field delineated in 2002 for the original FEIR, and this information was also referenced for the 2010 field delineations. Wetland resource areas were also delineated along the Whittenton Branch, and impacts to these wetland resource areas were calculated for both state and federal resource area types as well as by cover type. Wetlands along the Attleboro Secondary associated with the Whittenton alternative could not be field inspected due to lack of access, but the majority of the Attleboro Secondary runs through developed areas of Taunton.

---

[19] U.S. Army Corps of Engineers (USACE) and U.S. Environmental Protection Agency, Clean Water Act Jurisdiction Following the U.S. Supreme Court’s Decision in Rapanos v. United States & Carabell v. United States, June 6, 2007, revised December 2, 2008.

4.16.5.1 Delineation Criteria for Vegetated Wetlands

Vegetated wetlands and waterways were identified and delineated using the methods and criteria established in the 1987 Corps Manual and the 2012 Northcentral-Northeast Regional Supplement, as well as the 1995 State Manual. Potential wetland resource areas were examined by field investigators using these criteria all along the South Coast Rail project corridor. To document conditions in each identified wetland resource area, a representative observation point was selected, and field data sheets were completed describing the upland and wetland characteristics of the observation point.

Wetland areas were delineated in the field between March 2010 and August 2010. Wherever wetland resource areas occurred, points to designate the boundaries were marked with colored flagging. Points were also located with a Trimble® Model [No] hand-held GPS device.

Hydrophytic Vegetation

Visual estimates of species abundance were made for the upland and wetland plant communities at each observation point, and the dominant species were determined and recorded by genus and species on field data sheets. Dominant species were determined separately for each vegetative stratum as trees, saplings/shrubs, herbs, and vines.

The wetland indicator status of each species was determined according to the 1988 *National List of Plant Species That Occur in Wetlands: Region 1, Northeast*, which is based on the national list[20] According to the Regional Supplement, three separate procedures exist to determine whether an area has hydrophytic vegetation: the rapid test for hydrophytic vegetation, the dominance test, and the prevalence index. These procedures are discussed in detail in the Regional Supplement. All three methods were considered when evaluating site conditions.

Soils

Baseline soils information was determined from review of existing data, including the USDA NRCS Soils Surveys of Bristol, Plymouth, and Norfolk/Suffolk counties of Massachusetts,[21] county and state lists of hydric soils, and data collected from the previous wetland delineations.

During wetland investigation, soils were examined with a hand auger to determine if hydric soil characteristics were present. Auger holes were excavated to a depth that confirmed the presence of hydric soils in wetland areas, or that eliminated the possibility of hydric soils in uplands. Instances of auger refusal often occurred at a depth of only a few inches due to the subsurface conditions of the large disturbance area associated with existing railroad beds. The colors of the soil matrix and any redoximorphic features were described using Munsell® Soil Color Charts. Information describing the upland and wetland soil profiles was recorded on the field data sheets for each identified wetland.

Hydrology

Site hydrology was determined in the field based on properties such as soil saturation, inundation, oxidized root zones, manganese concretions, drainage patterns, and proximity to a perennial waterway.

Hydrologic indicators were based on the 1987 Corps Manual, the 2012 Northcentral-Northeast Regional Supplement, and the 1995 State Manual.

4.16.5.2 Delineation Criteria for Other Resource Areas

The following sections describe the criteria used to determine the boundaries of other resource areas.

Bank

Bank was delineated according to Massachusetts regulations (310 CMR 10.54) (Waterbodies were identified, including perennial and intermittent streams as well any ponds, and Bank flags were hung at the first observable break in the slope.

Land under Waterbodies and Waterways (LUW)

Land under Waterbodies and Waterways (LUW) was based on the delineation of Bank. In areas that contain a perennial stream or pond, LUW extends downgradient from Bank flags.

Bordering Land Subject to Flooding (BLSF)

Bordering Land Subject to Flooding (BLSF, (310 CMR 10.56) was not delineated in the field. The extent of this resource area is based off of published Federal Emergency Management Agency (FEMA) flood elevations, which estimate the elevations to which water would flood during a 100-year storm event[22]; any area below this elevation to the Bank of a corresponding WW or a Bordering Vegetated Wetland is BLSF. A measurement of BLSF is therefore a volume and not an area, and requires detailed topography of a given area in order to accurately measure. However, for BLSF, ILSF, and LSCSF, only the area of impact has been estimated, rather than the total volume of impact to these resource areas. Since detailed topography along the South Coast Rail project corridor does not exist, the volume of impact to these resource areas cannot be calculated with accuracy.

Isolated Land Subject to Flooding (ILSF)

As with BLSF, Isolated Land Subject to Flooding (ILSF, (310 CMR 10.57)) cannot be calculated for a given area with accuracy without more detailed topographic information than is currently available. ILSF areas were identified along the project corridor only when they were already known to be ILSF from previous plans, or when they were positively identified as ILSF by visual observation and estimation of their ability to hold one quarter-acre foot of water at an average depth of 6 inches.

Riverfront Area (RA)

Riverfront Area (RA, (310 CMR 10.58)) was not delineated in the field. Measurement of these resource areas is based on the delineation of Bank. In areas that contain a perennial stream or pond, RA extends upgradient from Bank flags.

Land Subject to Coastal Storm Flowage (LSCSF)

Land Subject to Coastal Storm Flowage (LSCSF) was not delineated in the field. See the discussion of BLSF for a description of how the area of LSCSF was estimated.

---

[22] A "100-year storm event" has a 1 percent probability of occurring in any given year.

Coastal Bank

Coastal Bank was delineated according to Massachusetts regulations ((310 CMR 10.30). Coastal Waterbodies were identified, and Coastal Bank flags were hung on the seaward face at the landward edge of any elevated landform.

Once wetland resource areas had been delineated in the field, the coordinates of all BVW, IVW, Bank, and Coastal Bank flags were incorporated into CAD plot plans showing the track design for the project. These plans were generated for each municipality and showed the track, the limit of the right-of-way, any wetland resource areas that were delineated, and topography using 5-foot contours. Finally, areas of BLSF, RA, and LSCSF were generated on the plans.

4.16.5.3 Federal and Municipal Review

The USACE has reviewed and verified the delineated boundaries. In addition to federal review by the USACE, the Secretary's Certificate called for plans to be presented to each municipality as part of an ANRAD submission, to allow the Conservation Commission in each municipality to review the delineations. The materials in the ANRAD for each municipality included the plot plans as well as field data forms documenting the delineation for each wetland resource area.

In 2011, ANRADs were submitted to all ten municipalities through which the South Coast Rail project passes. In each municipality, the filing was reviewed by the Conservation Commission through a public hearing process. Several municipalities retained outside consultants to review the delineation. All ANRAD submissions were also submitted to the Massachusetts Department of Environmental Protection (MassDEP) for state review.

> Three municipalities (Stoughton, Easton, and Raynham) elected not to review BLSF or ILSF because the 5-foot topographic contours on the plot plans were not sufficiently accurate enough to allow for a precise delineation of these resource areas. Since a full topographic survey at 1-foot contour intervals is outside the current scope of the South Coast Rail project, these areas were withdrawn from the ANRAD submissions in these municipalities.

Table 4.16-2 contains a summary of the municipalities in which ANRADs were filed, the file number issued by MassDEP for each ANRAD, the date any Order of Resource Area Delineation (ORAD) was issued, and whether any resource areas were excluded from the ORAD.

Table 4.16-2 Summary of ANRAD Reviews

Municipality	MassDEP File Number	Date ANRAD Submitted	Date ORAD Issued	Resource Areas Excluded from ORAD
Canton	SE 124-1083	October 2011	April 2012	none
Stoughton	SE 298-0709	October 2011	June 2012	BLSF, ILSF
Easton	SE 152-1349	October 2011	August 2012[1]	BLSF, ILSF
Raynham	SE 269-0880	November 2011	August 2012	BLSF, ILSF
Taunton	SE 073-2472	May 2011	August 2011	Wetlands along CSX-controlled track (lack of access)
Berkley	SE 004-0512	April 2011	June 2011	none
Lakeville	SE 192-0642	April 2011	February 2012	none
Freetown	SE 026-0510	June 2011	January 2012	Freetown Station
New Bedford	SE 049-0664	April 2011	July 2011	none
Fall River	SE 024-0614	May 2011	July 2011	none

1 Easton issued an ORAD rejecting the delineation on April 11, 2012; this filing was appealed with MassDEP and a Superseding ORAD was issued on August 29, 2012.

4.16.6 Wetland Functions, Values, and Significant Interests

Wetlands, watercourses, and water bodies may provide a variety of functions and values, such as wildlife habitat, fish habitat, visual/aesthetic quality, water-based recreation, flood storage and storm damage prevention, groundwater and surface water quality and quantity, pollutant attenuation through nutrient retention and sediment trapping, shoreline stabilization, and dissipation of erosive forces. Ecological functions and societal values vary with each wetland. Factors affecting wetland function include size, location in the watershed, number and interspersion of plant cover types, and the degree of disturbance.

The WPA regulations list eight functions and values, defined as significant interests, provided by wetland resource areas. These are:

- Protection of public and private water supply;
- Protection of ground water supply;
- Flood control;
- Storm damage prevention;
- Prevention of pollution;
- Protection of land containing shellfish;
- Protection of fisheries; and
- Protection of wildlife habitat.

The regulations presume that each wetland resource area is significant to some or all of these interests. These presumptions are rebuttable under the regulations in cases where the resource area has been altered by development or other human activities.

Table 4.16-3 summarizes the regulatory presumptions for each state-regulated inland wetland resource area.

Table 4.16-3 State Wetland Resource Area Presumptions of Significance

	LUW	Bank	BVW	BLSF[1]	ILSF[2]	Riverfront Area[3]	Coastal Bank
Public and Private Water Supply	x	x	x	-	x[2]	x	-
Ground Water Supply	x	x	x	-	x[2]	x	-
Flood Control	x	x	x	x	x	x	-
Storm Damage Prevention	x	x	x	x	x	x	x
Prevention of Pollution	x	x	x	-	x	x	x
Fisheries	x	x	x	-	-	x	-
Land Containing Shellfish	-	-	-	-	-	x	-
Wildlife Habitat	x	x	x	x	x	x	-

1 Only those areas within the 10-year floodplain, or within 100 feet of bank or BVW (provided those areas are within the 100-year floodplain) and all vernal pool habitat within the 100-year floodplain, except for those portions which have been so extensively altered that their important wildlife habitat functions have been eliminated.

2 ILSF is presumed significant to Public and Private Water Supply and Ground Water Supply when underlain by pervious material. When it is underlain by organic material it is presumed significant to Prevention of Pollution. Vernal Pool habitat within ILSF is significant to Wildlife Habitat.

3 Riverfront Area is presumed significant to the protection of Land Containing Shellfish only when associated with coastal waterbodies.

BVWs are federally regulated under Section 404. There are also several wetlands adjacent to or within the project alternatives corridors that meet the regulatory criteria for wetlands under Section 404 of the Federal Clean Water Act because they are dominated by wetland plants and have hydric soils.

The Army Corps of Engineers New England District method for assessing wetland functions and values [23] was employed for the South Coast Rail project. The methodology considers eight wetland functions and five wetland values in a Section 404 permit application:

Wetland Functions:

- Floodflow Alteration;
- Fish and Shellfish Habitat (Aquatic Diversity/Abundance);
- Sediment/Toxicant Retention (Pollutant Attenuation);

---

[23] USACE. 1999. *The Highway Methodology Workbook Supplement, Wetland Functions and Values - a Descriptive Approach*. New England District, U.S. Army Corps of Engineers, NAEEP-360-1-30a. Concord, MA.

- Nutrient Removal/ Retention/Transformation (Pollutant Attenuation);
- Production Export (Nutrient);
- Wildlife Habitat;
- Uniqueness/Heritage; and
- Recreation (Consumptive/Non-Consumptive).

Wetland Values:

- Groundwater Recharge/Discharge
- Sediment/Shoreline Stabilization
- Educational/Scientific Value
- Visual Quality/Aesthetics
- Threatened or Endangered Species Habitat

Floodflow Alteration (Storage/Desynchronization)

Wetlands can be important in the storage and desynchronization of floodwaters, protecting downstream resources from flood damage. Wetlands high in the watershed with constricted outlets or closed basins are generally important in capturing and detaining floodwaters. Other wetland characteristics that contribute to flood storage and desynchronization include broad floodplains and plant communities consisting of low, dense vegetation.

Study area wetlands designated as having floodflow desynchronization functions are identified by considering the local topography (broad, relatively flat areas), size, presence of ponded water, contiguous/branched channels, well vegetated floodplains along rivers and larger streams, and position in the landscape. The location of culverted streams within the right-of-way provides a means for retaining floodwaters higher in the watershed.

Fish and Shellfish Habitat (Aquatic Diversity/Abundance)

Large wetlands contiguous to a large, perennial stream or waterbody capable of supporting large fish and/or shellfish populations are important in providing Aquatic Diversity/Abundance. Other wetland characteristics that contribute to Aquatic Diversity/Abundance include good water quality, an abundance of shoreline vegetation, objects or vegetation that provide cover, spawning areas such as beds of submerged aquatic vegetation or gravel beds, and the lack of barriers such as dams and waterfalls, which prevent fish movement.

Sediment/Toxicant Retention (Pollutant Attenuation)

Wetland basins with permeable soils that detain storm and flood waters and promote percolation reduce runoff rates sufficiently to allow sediments and the adsorbed toxicants to settle from the water column. Diffuse channels, deep pools, and dense low vegetation are wetland characteristics that may also contribute to this process by slowing water velocities.

Nutrient Removal/Retention/Transformation (Pollutant Attenuation)

Wetlands can serve as a filter for the removal or detention of nutrients carried in surface water flows. Many wetland plants respond to high nutrient concentrations with accelerated rates. Some nutrients are assimilated in plant material while others are trapped in organic sediments in wetlands by chemical, physical, and biotic actions.

Study area wetlands designated as having nutrient removal functions are identified by the presence of large areas of open or ponded water with dense emergent vegetation, meandering streams with slow water velocities (supporting aggradations), and contiguous/branched channels.

Production Export (Nutrient)

Production export is the production of organic material and its subsequent transport out of a wetland to downstream areas or to deeper waters within the basin. This organic material is then added to the food chain where it is eaten by fish and other aquatic organisms. Wetlands with dense vegetation dominated by non-persistent emergent vegetation are important in supplying downstream wetlands with organic material. Wetlands dominated by shallow marshes with a perennial stream flowing from them are most important in providing production export.

Wetlands designated as having production export functions are classified by the presence of high densities and diversity of hydrophytic vegetation, presence of abundant fish and wildlife and downstream/downgradient evidence of export.

Wildlife Habitat

Large, undisturbed wetlands greater than 1 acre are generally considered to provide important wildlife habitat functions. Other factors that contribute to the provision of important wildlife habitat include the presence of shallow, permanent open water of good quality; proximity to undisturbed upland wildlife habitat; a high degree of interspersion of vegetation classes; a high degree of species and structural diversity within the vegetational community; high vegetation density; and the presence of wildlife food plants. Wetlands that are contiguous to other wetland areas may serve as travel or migratory corridors for wetland wildlife. Presence of vernal pools (ephemeral bodies of water that lack fish populations) connote a high wildlife value because several wildlife species, in addition to the obligate vernal pool species such as wood frog (*Rana sylvatica*) and ambystomid salamanders (*Ambystoma* spp.), use vernal pools and the areas immediately adjacent for feeding, cover, courtship, and overwintering habitat.

Size, adjacent land use, water quality, and presence of vernal pools are used to classify wetlands as important wildlife habitat for waterfowl, reptiles and amphibians, terrestrial bird species, and mammals.

Uniqueness/Heritage

The Uniqueness/Heritage function includes considerations of science, the endangerment of the wetland, and the importance of the wetland in the context of its local and regional environment. The wetland may contain areas of archaeological, historical, or social significance, or it may represent the last fragment of its wetland type in an urbanized or agricultural environment. The presence of relatively scarce wetland habitats or wetland species contributes to the Uniqueness/Heritage function provided by the wetland. Areas containing Estimated Habitats of Rare Wildlife (Estimated Habitat) or Priority Habitats of Rare Species (Priority Habitat) mapped by the Massachusetts Natural Heritage and Endangered Species Program (NHESP) confer a higher value in this category.

Recreation (Consumptive/Non-Consumptive)

Wetlands designated as having Recreational value are classified based on the suitability of the wetland and associated watercourses to provide recreational opportunities such as hiking, canoeing, boating, fishing, hunting and other recreational activities. Consumptive opportunities, such as fishing and hunting, consume or diminish the plants, animals, or other resources that are intrinsic to the wetland. Non-consumptive opportunities do not diminish these resources of the wetland.

4.16.7 Impact Assessment Methodology

4.16.7.1 Quantification of Direct Impacts

As required by the National Environmental Policy Act (NEPA) Council on Environmental Quality (CEQ) regulations,[24] the analysis of the environmental consequences requires discussion of the direct and indirect effects of a proposed action, and their significance. Direct effects are defined as those "which are caused by the action and occur at the same time and place."[25] Indirect effects are defined as those "which are caused by the action and are later in time or farther removed in distance, but are still reasonably foreseeable. Indirect effects may include growth inducing effects and other effects related to induced changes in the pattern of land use, population density or growth rate, and related effects on air and water and other natural systems, including ecosystems."[26] These types of indirect effects are further discussed in Chapter 5, *Indirect Effects and Cumulative Impacts*.

The Massachusetts Environmental Policy Act (MEPA) requires "a detailed description and assessment of the negative and positive potential environmental impacts of the alternatives. The EIR [Environmental Impact Report] shall assess (in quantitative terms, to the maximum extent practicable) the direct and indirect potential environmental impacts from the Project that are within the Scope. The assessment shall include both short-term and long-term impacts for all phases of the Project (e.g., acquisition, development, and operation) and cumulative impacts of the Project, any other Projects, and other work or activity in the immediate surroundings and region."[27] Cumulative impacts are discussed in Chapter 5, *Indirect Effects and Cumulative Impacts*.

Direct wetland impacts, both temporary and permanent, are anticipated along each of the proposed alternatives. Each alternative corridor was assessed for the presence of wetland resources within and adjacent to the right-of-way, and the impacts associated with them. Permanent impacts are the loss of a wetland resource area following construction. Permanent impacts may result from, but are not limited to, wetland fill, dredging, and watercourse relocation or alteration.

Temporary impacts that may occur along the right-of-way include work areas adjacent to the alignment, placing erosion control devices including hay bales and silt fences, vegetation removal, and any indirect impact that could result from the migration of exposed soils. Examples of temporary impacts include short-term disturbances to wetlands and waterways during construction that would cease once construction activities are complete. These may include, but are not limited to, installing erosion

controls, establishing work areas, or installing temporary structures at stream crossings. Section 4.16.9.4, *Temporary Construction-Period Impacts*, discusses these in greater detail and describes how these impacts would be mitigated.

As described in the Existing Conditions section, each impacted wetland along the proposed alternatives was also evaluated for its functions and values as well as the ability of each wetland to protect the interests of the Act. The evaluation was based on eight functions and five values as described and outlined by the United States Army Corps of Engineers, New England District.[28] The wetlands were evaluated using GIS data layers, orthophotos, and visual inspections of critical areas. Functions and values of impacted wetlands are shown on the figures illustrating each rail and roadway segment. These graphics show the functions and values, cover type, and total area of permanent loss for each impacted wetland. This information is presented in the large (1.75 x 1.75-inch) boxes. Where a large wetland would be impacted in several locations, smaller (1 x 1.25-inch) boxes are shown for each localized area of impact. These boxes show the cover type and amount of wetland loss in a specific sub-area of a larger wetland. Detailed information is provided about the total area of each wetland, the amount of impacted area, and the impacted cover types.

Once the wetland resource areas had been delineated and the preliminary track layout was determined, direct impacts to wetland resource areas were quantified. The quantification of direct impacts was performed using CAD analysis of the layout of the track, all wetland resource areas, and the limit of disturbance of the project. The limit of disturbance represents the limit of permanent alteration associated with the South Coast Rail project.

Direct impacts were calculated as being either permanent or temporary. Permanent impacts are any direct impact (fill) to wetland resource areas that are within the limit of disturbance. These impacts include fill, retaining walls, and other disturbance and structures that will remain in place and permanently impact the wetland resource area. Permanent impacts were determined by calculating the areas of any portion of a wetland resource area inside the limit of disturbance.

Permanent impacts were calculated for all wetland resource areas: BVW, LUW, IVW, Bank, RA, BLSF, ILSF, and LSCSF. For BLSF, ILSF, and LSCSF, only the area of impact has been estimated, rather than the total volume of impact to these resource areas. Impacts to RA were calculated as those impacts to the area within 200 feet of a perennial waterway that would constitute new development of previously undeveloped land. Previously developed (impervious surface) areas were estimated by overlaying a MassGIS data layer of mapped developed areas over the project corridor. Areas of impact to RA outside these previously developed areas were calculated as new impact. Temporary and permanent impacts to Outstanding Resource Waters (ORWs) were determined by identifying BVWs that contained a vernal pool within 100 feet of the right-of-way. These determinations are conservative and included certified vernal pools (CVPs), potential vernal pools (PVPs), and vernal pools that have been field verified in support of the South Coast Rail project (SCR-VPs). Because vernal pool boundaries have not been field delineated, the limit of the BVW associated with the vernal pool was assumed to be the boundary of the vernal pool. Prior to final design, actual vernal pool boundaries would be field delineated to enable a more refined assessment of impact to ORWs. Additional information on potential impacts to vernal pools can be found in Chapter 4.14, *Biodiversity, Wildlife and Vegetation*. Fall Brook in Freetown and

[28] U.S. Army Corps of Engineers, New England District. 1999. *The Highway Methodology Workbook Supplement,* US Army Corps of Engineers, New England District Tech. Rept. NAEEP-360-1-30a, 32pp.

Black Brook in Easton are also listed as ORWs and impacts to these resources are included in the analysis.

Temporary impacts represent unavoidable disturbances to the wetland associated with constructing the project which will not impact the wetland longer than the period of construction. These impacts mainly arise from the necessity of crew and machinery to work beyond the limit of disturbance in order to construct slopes, retaining walls, and other portions of the project. The limit of temporary impacts was estimated by establishing an area 4 feet wide outside the limit of disturbance. Temporary impacts were calculated for BVW, LUW, and IVW because these areas are ecologically wetlands. Temporary impacts within state-jurisdictional wetland resource areas that are ecologically upland (BLSF, RA) were not calculated at this level of design.

4.16.7.2 Secondary and/or Indirect Impact Analysis Methodology

Secondary (indirect) effects are defined in USEPA Regulations at 40 CFR Part 230.11.[29] The USEPA regulations state that "Secondary effects are effects on an aquatic ecosystem that are associated with a discharge of dredged or fill materials, but do not result from the actual placement of the dredged or fill material." Additionally, although not specifically addressing impacts to aquatic resources, the CEQ NEPA regulations at 40 CFR Part 1508.8[30] define indirect effects as "effects, which are caused by the action and are later in time or farther removed in distance, but are still reasonably foreseeable. Indirect effects many include related effects on air and water and other natural systems, including ecosystems".

Secondary and/or indirect impacts are therefore the consequences of an action's direct impacts. For example, while the direct impact of filling a wetland would be the loss of the filled wetland area and the functions and values provided by that specific area, the secondary and/or indirect impacts of that wetland fill would result from the associated changes to the overall size of the wetland, hydrology, cover type, species assemblage, or degree of habitat fragmentation. These types of impacts could adversely affect the ability of the wetland to provide functions and values, or could diminish the functions and values to a degree greater than would be attributed simply due to the loss of area. Isolated fragments of wetlands or waterways may have reduced habitat value, no longer provide viable fish or wildlife habitat or be so isolated that the wetland or waterway fragments are rendered inaccessible to many fish or other aquatic species.

Methodology and Criteria for Evaluation

MassDOT met with the South Coast Rail Interagency Coordinating Group (ICG) in 2012 to develop a methodology for evaluating secondary and/or indirect impacts to wetlands from the South Coast Rail project. The methodology was presented in a memorandum prepared by MassDOT that incorporated ICG comments (Appendix 4.16-B).

The assessment of secondary and/or indirect impacts focuses on wetlands within 100 feet of the right-of-way along the South Coast Rail project corridor. At the request of the ICG, MassDOT was asked to consider assessing additional secondary and/or indirect impacts more than 100 feet from the right-of-way. Based on a literature review and a solid understanding of the construction and operations

---

[29] 40 CFR §230.11, Factual Determinations. Available on line at: http://ecfr.gpoaccess.gov/cgi/t/text/text-idx?c=ecfr&tpl=/ecfrbrowse/Title40/40cfr230_main_02.tpl, accessed June 1, 2012.

[30] 40 CFR §1508.8, Effects. http://ecfr.gpoaccess.gov/cgi/t/text/text-idx?c=ecfr&tpl=/ecfrbrowse/Title40/40cfr1508_main_02.tpl, accessed June 1, 2012.

of the South Coast Rail corridor, in comparison to the road-effects of new road construction or an operating highway, MassDOT concluded that there is no scientific basis for considering the South Coast Rail project's "road effect zone" for impacts to aquatic resources to extend further than 100 feet from the right-of-way.

The methodology developed by MassDOT to assess secondary and/or indirect impacts is a stepwise process that first evaluates any direct impacts to a given wetland, and then assesses the result of those impacts on the functions and values that the wetland provides, using a checklist of potential effects developed by MassDOT. The checklist is based on "considerations and qualifiers" for each wetland function and value, based on those outlined in a document prepared by the USACE New England Division.[31] These considerations and qualifiers are identified as the principal characteristics that contribute to the ability of each wetland to provide the indicated function or value. If the direct wetland impact of the proposed action alters these characteristics, it is presumed to alter the ability of the wetland to continue to provide the associated function or value.

For this analysis, secondary and/or indirect impacts to wetlands and other Waters of the United States include the following effects that could be caused by the placement of fill within jurisdictional wetlands, but occur at a different location or time:

- Changes in wetland functions; or
- Changes in wetland physical/biological characteristics as a result of the direct impacts (loss of wetland).

The types of direct impacts and the secondary and/or indirect impacts that may result include:

- Filling a portion of a wetland (loss of)–reduction in wetland size, introducing human activity (noise, disturbance);
- Dredging a wetland/pond–change in hydrology, vegetation, habitat;
- Constructing a berm across a wetland–change in hydrology, fragmentation, introduction of disturbed non-wetland conditions, creation of new "edge", interrupt migratory routes;
- Installing a new culvert or changing existing culvert–alter water levels or flow patterns;
- Removing canopy or other vegetation–change light regimes, water temperature, plan community structure;
- Relocating a stream– change flow characteristics; or
- A new discharge of stormwater–alter water levels or flow patterns, or introduce sediments or nutrients.

[31] The Highway Methodology Workbook Supplement, Wetland Functions and Values - a Descriptive Approach. USACE NED, 1999.

Assessment of Secondary and/or Indirect Impacts

Secondary and/or indirect impacts to wetlands were assessed for each within 100 feet of the Stoughton and Whittenton Lines between Brock Street in Stoughton and the terminal stations of the New Bedford Main Line in New Bedford and the Fall River Secondary Fall River, based on the functions and values that the wetland provides and the type and extent of the direct wetland impact and/or work adjacent to the wetland that is the cause of the secondary and/or indirect impact. The steps of this process are:

- For each wetland, identify the type of direct impact:
- Loss of wetland area due to placement of fill
- New culvert
- Replacement of existing culvert

Other

- Direct discharge of untreated stormwater from a pollutant source
- For each wetland, identify the type of work occurring within 100 feet of the wetland:
- Improvement of existing freight or commuter rail tracks and increased train service
- Replacement of track infrastructure on out-of-service rail and addition of train service, and
- Evaluate secondary and/or indirect impacts based on function-specific considerations using the attached checklist.

The list of potential effects on functions and values is based on the "considerations and qualifiers" for each wetland function and value, as presented in the Corps' "*Highway Methodology Workbook Supplement – Wetland Functions and Values, a Descriptive Approach*" (September 1999). These characteristics are identified in the Workbook Supplement as the principal characteristics that contribute to the ability of each wetland to provide the indicated function or value. If the direct wetland impact of the proposed action altered these characteristics, it is presumed to alter the ability of the wetland to continue to provide these functions.

4.16.8 Existing Conditions

4.16.8.1 Overview

Major Watersheds

The South Coast Rail alternatives as presented in the DEIS/DEIR pass through several watersheds associated with southeastern Massachusetts. Watersheds have become an important measure of the overall health and the capacity of a region to handle both stormwater and pollutant loading. The alternatives proposed in the DEIS/DEIR (Figure 4.16-1) cross through the Boston Harbor Regional Watershed, the Taunton River Regional Watershed, the Charles River Regional Watershed, and the Buzzards Bay Regional Watershed and are characterized by highly populated and densely populated municipalities and sparsely developed rural areas.

Boston Harbor Regional Watershed

The Boston Harbor regional watershed receives water from approximately 293 square miles in the greater Boston area. It is made up of the Mystic River, Neponset River, Fore, Back, and Weir River watersheds and includes 45 municipalities.

Buzzards Bay Regional Watershed

The Buzzards Bay regional watershed receives water from approximately 432 square miles of land in southeastern Massachusetts. The watershed takes water from lakes, rivers, streams, wetlands and groundwater that eventually drain into Buzzards Bay. Buzzards Bay is approximately 228 square miles and offers important habitat features including salt marsh, eelgrass beds, and tidal flats. It includes at least part of 15 municipalities.

Charles River Regional Watershed

The Charles River regional watershed is comprised of approximately 308 square miles and is part of 35 municipalities. This watershed is centered on the Charles River and extends from Hopkinton east to Boston Harbor. The Charles River and, consequently, its watershed have gone through cleanup efforts over the past several years resulting in a healthier, more productive ecosystem that is able to support a greater diversity of flora and fauna.

Taunton River Regional Watershed

The Taunton River regional watershed is the second largest watershed in the state, and the largest that any proposed alternative would cross. The watershed consists of 562 square miles of land, with 94 square miles of wetlands. The Hockomock Swamp is part of this regional watershed.

Major Wetland Systems

Typical wetland resource areas within the study area consist of extensive red maple (*Acer rubrum*) swamps, Atlantic white cedar (*Chamaecyparis thyoides*) swamps, river systems with surrounding red maple swamp and shrub swamps, and small isolated wetlands. The majority of the red maple swamps (such as Hockomock Swamp) have a closed tree canopy dominated by red maple and an understory dominated by arrow-wood (*Viburnum dentatum*), silky dogwood (*Cornus amomum*), highbush blueberry (*Vaccinium corymbosum*), and sweet pepperbush (*Clethra alnifolia*). The Atlantic white cedar swamps, including portions of the Hockomock Swamp, Pine Swamp, Assonet Cedar Swamp, and Acushnet Cedar Swamp, have a closed tree canopy dominated by Atlantic white cedar and red maple with an understory dominated by highbush blueberry, arrow-wood, and sweet pepperbush.

The following sections describe the major wetland systems that are adjacent to or found within the alternatives corridors. These major wetland systems are shown in Figure 4.14-1.

Fowl Meadow and Ponkapoag Bog

The Fowl Meadow and Ponkapoag Bog ACEC covers approximately 8,350 acres in the metropolitan Boston area, including parts of Boston, Canton, Dedham, Milton, Norwood, Randolph, Sharon, and Westwood (Figure 4.14-2). The ACEC is fragmented by several transportation corridors, including I-95, I-93, Route 24, Route 138, Route 1, and other roadways. It also includes upland areas that are developed in commercial and residential land uses as well as undeveloped forested upland and farmland.

The central resource features of the Fowl Meadow and Ponkapoag Bog ACEC are the Neponset River and the Ponkapoag Pond and Bog. An 8-mile stretch of the Neponset River and its tributaries, the adjacent wetlands and floodplains, the associated aquifers and public water supplies, and the diverse habitats form the core resources of the Fowl Meadow area. Ponkapoag Bog and Pond and the associated natural communities and wildlife habitats form the core resources of the Ponkapoag Bog area. Historical and archaeological resources and the recreational and educational values of both areas support their overall importance to the people and communities of the area.

The Fowl Meadow area includes the largest wetland and floodplain areas in the Neponset River basin. There are several municipal public wells that provide water to the communities of Canton, Dedham, and Westwood. At least 13 state-listed rare species occur in the ACEC. The northern Fowl Meadow area and Ponkapoag Bog have been designated a National Environmental Study Area by the National Park Service. Approximately 2,330 acres of the ACEC are owned by DCR, and are managed as part of the Blue Hills Reservation.

The Northeast Corridor forms the eastern boundary of the ACEC between Neponset Street in Canton and I-95, and forms the western boundary of the ACEC southwest of the I-95/I-93 interchange. The Northeast Corridor passes through the ACEC north of I-95, where the rail line parallels the Neponset River.

Hockomock Swamp ACEC

The Hockomock Swamp ACEC and its associated wetlands and water bodies are described by the Massachusetts DCR as the largest vegetated freshwater wetland system in Massachusetts (Figure 4.14-2). The wetland system, which includes the Hockomock Swamp, the Dead Swamp, the Titicut Swamp, and the Little Cedar Swamps, serves as the headwaters of the Town River, a tributary of the Taunton River, and overlays a system of high and medium yield aquifers that supply public drinking water wells in Raynham and West Bridgewater. The Stoughton and Whittenton Alternatives pass through this area.

Pine Swamp

Pine Swamp is a 275-acre wetland system located in western Raynham that consists of several parcels that are owned by the Town of Raynham Conservation Commission. The Stoughton Alternative (Electric and Diesel) crosses a 1-mile segment of the swamp between King Phillip Street and East Brittania Street. This area consists of forested and marsh wetlands associated with Pine Swamp, an area that is located within mapped Estimated Habitat of several rare wetlands species and supports an Atlantic white cedar swamp community.

Although there are no trails or designated points of public entry, the former rail right-of-way is used by pedestrians, all-terrain vehicles, off-road motorbikes, and other vehicles. The Stoughton Line and the former railroad bed through the conservation area is owned by the Taunton Municipal Light Corporation (TMLC), and maintained as a utility corridor with an overhead power line. The TMLC periodically maintains the right-of-way by clearing vegetation on the right-of-way and in the adjacent wetland.

Assonet Cedar Swamp

The Assonet Cedar Swamp Wildlife Sanctuary is a 1,000-acre parcel of conservation land owned by Mass Audubon in Lakeville. The land is designated by the state for the preservation of habitat for several rare

species, including the Hessel's hairstreak butterfly (*Callophrys hesseli*). It is one the largest Atlantic white cedar swamps in the state. The New Bedford Main Line passes through this sanctuary.

Forge Pond

Forge Pond is an irregularly shaped surface waterbody located mainly on the southwestern side of the Fall River Secondary. The Forge Pond Dam (MA00800) is located on the south side of Forge Pond and is classified non-jurisdictional by the DCR. A wetland complex of trees, shrubs, and emergent vegetation exists between the pond's edge and the tracks in several areas, especially along the northern edge of the pond. In the northern area, the wetland complex borders the tracks for approximately 1,600 feet and includes BVW, Bank and BLSF.

Acushnet Cedar Swamp

The Acushnet Cedar Swamp State Reservation is an approximately 1,000-acre property located in New Bedford and Dartmouth, north of the New Bedford Airport. It is an outstanding example of an Atlantic white cedar swamp and provides habitat for state-listed rare wetlands wildlife and other state listed rare, endangered, or special concern species. This is one of eight cedar swamps in public ownership in Massachusetts, and has been designated by the U.S. Department of the Interior – National Park Service as a National Natural Landmark. The existing New Bedford Main Line, currently used for freight rail service, forms the eastern boundary of the State Reservation.

Three Mile River ACEC

The recently-designated Three Mile River Watershed ACEC covers approximately 14,275 acres in Dighton, Norton, and Taunton. The ACEC is fragmented by Route 140, a major transportation corridor, and several other major roadways. It includes substantial upland areas that are developed commercial and residential lands as well as undeveloped forested upland and farmland. The Attleboro Secondary passes through the Three Mile River Watershed ACEC from Barrowsville in Norton to Crane Avenue in Taunton. This ACEC provides habitat for at least seven species listed as rare, endangered, or of special concern by NHESP.

Canoe River Aquifer ACEC

The Canoe River Aquifer ACEC covers approximately 17,200 acres in Easton, Foxborough, Mansfield, Norton, Sharon, and Taunton. The associated areas within this ACEC include Snake River, Watson Pond, and Lake Sabbatia. The ACEC is fragmented by several major transportation corridors, including I-495, Route 123, Route 106, and other major roadways. It includes substantial upland areas that are developed commercial and residential lands as well as undeveloped forested upland and farmland. The Northeast Corridor forms the western boundary of the ACEC from Mohawk Street in Sharon to Oakland Street in Mansfield. This ACEC contains another good example of an Atlantic White Cedar swamp community.

4.16.8.2 Existing Conditions by Municipality

This section presents the results of the field delineations of wetland resource areas along the FEIS/FEIR South Coast Rail alternatives, including the station sites and layover facilities. The following sections describe the wetland resource areas present in each municipality along the project corridor. Each section includes a table listing the wetland resource areas, as confirmed by each municipality's Conservation Commission.

This report only addresses those resource areas that are either within or directly adjacent to the South Coast Rail project right-of-way, or within or directly adjacent to the area of proposed stations that could be directly affected by construction. Other wetlands exist within 100 feet of the right-of-way, and their approximate locations are shown in the figures that accompany Chapter 4, but they were not field delineated at this planning stage of the project because they would not be directly impacted.

Any wetlands that are designated as Outstanding Resource Waters (ORWs) have been highlighted in the tables below. Wetlands designated as ORWs include all vernal pool wetlands, regardless of their certification status. All vernal pools were designated as ORWs in this report because all vernal pools were assumed to be certified vernal pools when determining impacts. Vernal pools are discussed in detail in the Chapter 4.14, Biodiversity, Wildlife, and Vegetation*.*

Federal jurisdictional wetlands include the state-regulated Land Under a Waterbody/Waterway (LUW), Bordering Vegetated Wetlands (BVW), Isolated Land Subject to Flooding (ILSF), and well as other small Isolated Vegetated Wetlands (IVW) that are not subject to state jurisdiction.

Plans showing the locations of all delineated wetland resource areas are provided in Appendix 4.16-C.

Canton

The Canton segment of the Stoughton alternative is approximately 2.3 miles long and is an active commuter and freight service on the Stoughton Line. Ten wetlands are located along the right-of-way in Canton.

An ANRAD was submitted to the Canton Conservation Commission in September 2011. Wetlands in Canton are part of the Neponset River watershed, and are comprised of four individual wetland systems and four isolated federal wetlands. Forge Pond (Wetland CA 1) and Mill Brook (Wetland CA 2.1) are the two large wetland systems along this segment of right-of-way. Mill Brook, a perennial stream, is part of a larger wetland system that flows into Beaver Meadow Brook. Wetland CA 1 is a large wetland system just south of Canton Center that includes Forge Pond and its adjacent wetland.

Table 4.16-4 lists the wetlands delineated along the right-of-way in Canton and the resources associated with each wetland.

There are four isolated wetlands along this section of existing track (Wetlands CA B1, CA B, CA C, and CA D). These wetlands are small depressions that appear to contain water for limited periods and are vegetated by plant species known to occur in wetlands.

Table 4.16-4 Wetland Resource Areas–Canton

Stoughton

The Stoughton segment of the Stoughton alternative is approximately 4.2 miles long and contains active and inactive sections of the Stoughton Line. Twenty three wetlands are located along the right-of-way in Stoughton. The wetlands in Stoughton include forested areas dominated by red maple swamps and an unnamed perennial stream. An ANRAD was submitted to the Stoughton Conservation Commission in October 2011. The Commission issued an ORAD on June 19, 2012. Per the Commission's request, the resource areas of BLSF and ILSF were withdrawn from consideration. Table 4.16-5 lists the wetlands delineated along the right-of-way in Stoughton and the resources associated with each wetland.

Table 4.16-5 Wetland Resource Areas–Stoughton

1 Cowardin Types: OW = Open Water, PEM = Palustrine Emergent, PFO = Palustrine Forested, PSS = Palustrine Scrub/Shrub. Wetland Classifications: LUW=Land Under Water, BVW = Bordering Vegetated Wetland, IVW = Isolated Vegetated Wetland, RA = Riverfront Area, BLSF = Bordering Land Subject to Flooding, ILSF = Isolated Land Subject to Flooding.
2 BLSF and ILSF were withdrawn from the ANRAD application for Stoughton, and therefore neither resource area was confirmed by the Conservation Commission.
3 Shading denotes ORW.

Streams and wetlands along the right-of-way in Stoughton are part of two separate regional watersheds. Wetland systems in the northern portion of the town flow west and north into the Neponset River regional watershed, while wetlands flowing east and south are part of the Taunton River regional watershed. The Neponset River receives flow from Wetland ST 2, while the remaining wetlands south of Wetland ST 2 are tributaries to Whitman Brook, within the Taunton River watershed.

Blocked culverts and drainage ditches along the right-of-way have formed wetlands within the rail bed (Wetlands ST 6A (200 series), ST 6A (100 series), and ST 7). Wetland ST 2 (an unnamed perennial stream) flows under the tracks approximately 920 feet south of Brock Street. Wetland ST 9A is an intermittent

tributary to Whitman Brook that flows under the tracks approximately 1,170 feet south of the Stoughton Fish and Game Club access road.

Easton

The Easton segment of the Stoughton alternative is approximately 7.1 miles long and is an inactive portion of the Stoughton Line. Sixty-nine wetlands are located along the right-of-way in Easton. The wetlands in Easton include extensive forested areas dominated by red maple swamps, a large Atlantic white cedar swamp within the Hockomock Swamp, several emergent marshes, and four perennial streams. An ANRAD was submitted to the Easton Conservation Commission in October 2011. The Commission issued an ORAD rejecting the delineation of wetland resource areas on April 11, 2012; MassDEP issued a Superseding ORAD filed by MassDOT on August 29, 2012. Per the Commission's request, the resource areas of BLSF and ILSF were withdrawn from consideration. Table 4.16-6 lists the wetlands delineated along the right-of-way in Easton and the resources associated with each wetland.

Table 4.16-6 Wetland Resource Areas–Easton

1 Cowardin Types: OW = Open Water, PEM = Palustrine Emergent, PFO = Palustrine Forested, PSS = Palustrine Scrub/Shrub. Wetland Classifications: LUW=Land Under Water, BVW = Bordering Vegetated Wetland, IVW = Isolated Vegetated Wetland, RA = Riverfront Area, BLSF = Bordering Land Subject to Flooding, ILSF = Isolated Land Subject to Flooding.

2 BLSF and ILSF were withdrawn from the ANRAD application for Easton, and therefore neither resource area was confirmed by the Conservation Commission.

3 Shading denotes ORW.

Streams and wetlands along the right-of-way in Easton are part of the Taunton River regional watershed. Perennial streams and wetland systems along the right-of-way that discharge into this regional watershed include Whitman Brook, Queset Brook, Black Brook, and the Hockomock Swamp. Six of the fourteen stream crossings in Easton are perennial. These perennial stream crossings include Whitman Brook, Queset Brook, Black Brook, and a perennial tributary to Black Brook. Black Brook crosses the right-of-way in three separate locations. An intermittent stream has formed between Prospect Street and Purchase Street that flows in the right-of-way due to blocked culverts. This intermittent stream flows south and joins Wetland EA 96 that flows under Purchase Street. The right-of-way extends approximately 3.3 miles through the Hockomock Swamp ACEC. Wetlands EA 62 to EA 78, EA 99, and EA 102 are located within the ACEC.

Raynham

The Raynham segment of the Stoughton alternative is approximately 4.9 miles long and is an inactive portion of the Stoughton Line. Twenty-nine wetlands are located along the right-of-way in Raynham. The wetlands in Raynham include extensive forested areas dominated by red maple swamps, two wetlands that contain Atlantic white cedar swamps (Hockomock Swamp and Pine Swamp), and three perennial streams. An ANRAD was submitted to the Raynham Conservation Commission in November 2011. The Raynham ORAD was issued August 30, 2012. Table 4.16-7 lists the wetlands delineated along the right-of-way in Raynham and the resources associated with each wetland.

Streams and wetlands along the right-of-way in Raynham are part of the Taunton River regional watershed. Perennial streams and bordering wetlands along the right-of-way that discharge into this regional watershed include streams within the Hockomock Swamp, Pine Swamp, and Pine Swamp Brook. Changes in drainage patterns and inadequate drainage along the right-of-way, south of the former Greyhound Park access road, have formed a perennial stream in the right-of-way. Three of the

six streams that cross the right-of-way in Raynham are perennial. These unnamed streams are associated with Wetlands R 12.1 and R-12.2 (Pine Swamp Brook), R 62.1 (unnamed stream), and R 116 and R 113 (unnamed stream). The right-of-way in Raynham extends through Hockomock Swamp for approximately 2.0 miles. The right-of-way also extends through Pine Swamp (Wetland RA 12) for approximately 1.0 mile.

2 Shading denotes ORW.

The Raynham segment of the Whittenton Branch extends from Raynham Junction at Route 138 to the municipal border between Raynham and Taunton, approximately 1.2 miles. The entire length of this section is inactive. Four wetlands are located along the right-of-way of the Whittenton Branch in Raynham. These wetlands include forested areas dominated by red maple swamps, emergent marshes, and narrow wetlands along residential areas. One intermittent stream flows under the right-of-way. Streams and wetlands in Raynham are part of the Taunton River regional watershed. Table 4.16-8 lists the wetlands delineated along the right-of-way of the Whittenton Alternative in Raynham and the resources associated with each wetland.

2 Shading denotes ORW.

Taunton

In Taunton, the Stoughton alternative includes segments of both the Stoughton Line and the New Bedford Main Line. The New Bedford Main Line segment is controlled by CSX; this segment extends from Weir Junction to Cotley Junction The two segments form one continuous track through Taunton approximately 4.7 miles long. Forty-four wetlands are located along the right-of-way in Taunton; these wetlands include four wetlands delineated in the locations of two proposed stations. The wetlands in Taunton include extensive forested areas dominated by red maple swamps, several ponds, and three perennial streams including the Taunton River. An ANRAD was submitted to the Taunton Conservation Commission in May 2011. The Commission issued an ORAD on August 10, 2011. This ORAD did not include the wetlands along the CSX-controlled portion of the right-of-way in Taunton because of lack of access. This segment encompasses wetlands from TCM-1.3 to TCM-7 West. Table 4.16-9 lists the wetlands delineated along the Stoughton Line segment of the right-of-way in Taunton and the resources

associated with each wetland. Table 4.16-10 lists the wetlands delineated along the New Bedford line segment of the right-of-way in Taunton and the resources associated with each wetland.

Streams and wetlands along the right-of-way in Taunton are part of the Taunton River regional watershed. Wetlands and streams along the right-of-way that discharge into the Taunton River watershed include the Taunton River and Mill River systems. All six stream crossings along the right-of-way in Taunton are perennial. The tracks bridge the Taunton River in four separate locations, including three locations between Route 44 and High Street. The Taunton River (Wetlands TCM 1.1 and TCM 1.2) flows under the tracks for a fourth time between Ingell and Hart Streets. The Mill River (Wetland T 33) is bridged by the tracks just north of High Street. Three wetlands (Wetlands 1, 2, and 3) are not in the right-of-way but are adjacent to the proposed Taunton Station site.

The Taunton segment of the Whittenton Branch extends from Raynham Junction, at the municipal border between Raynham and Taunton to Whittenton Junction, approximately 2.2 miles. The entire

length of this section is inactive. The Attleboro Secondary Line, an active rail line, extends from Whittenton Junction to Weir Junction, approximately 2.4 miles. Wetland inspections were not able to be performed along this active section of track due to lack of access. The majority of this section of track (approximately 1.7 miles) is a densely developed area between Danforth Street and Weir Junction. The remaining stretch of tracks between Whittenton Junction and Danforth Street (approximately 0.7 mile) was assessed using available information.

Thirteen wetlands are located along the right-of-way of the Whittenton Branch in Taunton, plus one additional isolated wetland along the Attleboro Secondary that was identified using available information. These 18 wetlands include forested areas dominated by red maple swamps, one Atlantic white cedar swamp, emergent marshes, and one perennial stream, the Mill River. Five additional intermittent streams flow under the right-of-way. Streams and wetlands are part of the Taunton River regional watershed. Table 4.16-11 lists the wetlands delineated along the right-of-way of the Whittenton Branch and New Bedford Main Line in Taunton and the resources associated with each wetland.

Berkley

In Berkley, the Stoughton alternative includes segments of both the New Bedford Main Line and the Fall River Secondary, both of which currently have active freight service. The New Bedford Main Line has approximately 2.9 miles of right-of-way, while the Fall River Secondary Line has approximately 0.8 mile of right-of-way, for a total of approximately 3.7 miles of right-of-way in Berkley.

Twenty-eight wetlands are located along the right-of-way in Berkley. Twenty wetlands occur along the New Bedford Main Line, while eight wetlands occur along the Fall River Secondary. The wetlands in Berkley include extensive forested areas dominated by red maple swamps and six perennial streams. An

ANRAD was submitted to the Berkley Conservation Commission in April 2011. The Commission issued an ORAD on June 1, 2011.

Table 4.16-12 lists the wetlands delineated along the New Bedford Main Line segment of the right-of-way in Berkley and the resources associated with each wetland. Table 4.16-13 lists the wetlands delineated along the Fall River Secondary segment of the right-of-way in Berkley and the resources associated with each wetland.

2 Shading denotes ORW.

Streams and bordering wetlands along the right-of-way in Berkley are part of the Taunton River regional watershed. The Cotley River and its bordering wetlands (Wetlands BKCM 4, 10, and 18) form the major wetland system along the right-of-way that discharges into the Taunton River. Six of the nine streams that cross the right-of-way in Berkley are perennial. Two of the perennial stream crossings are tributaries to the Cotley River, and are located between Cotley Street and Padelford Street. The Cotley River is bridged by the tracks approximately 3,500 feet south of Cotley Street, and approximately 2,800 feet south of the first crossing.

Lakeville

In Lakeville, the Stoughton alternative includes segments of both the New Bedford Main Line and the Fall River Secondary, both of which currently have active freight service. The New Bedford Main Line has approximately 3.5 miles of right-of-way, while the Fall River Secondary has approximately 0.3 mile of right-of-way, for a total of approximately 3.8 miles of right-of-way in Lakeville.

Twenty-five wetlands are located along the right-of-way in Lakeville. Nineteen wetlands occur along the New Bedford Main Line, while six wetlands occur along the Fall River Secondary. The wetlands in Lakeville include an extensive forested area dominated by red maple swamps and three perennial streams. An ANRAD was submitted to the Lakeville Conservation Commission in April 2011. The Commission issued an ORAD in March 2012.

Table 4.16-14 lists the wetlands delineated along the New Bedford Main Line segment of the right-of-way in Lakeville and the resources associated with each wetland. Table 4.16-15 lists the wetlands delineated along the Fall River Secondary segment of the right-of-way in Lakeville and the resources associated with each wetland.

1 Cowardin Types: OW = Open Water, PEM = Palustrine Emergent, PFO = Palustrine Forested, PSS = Palustrine Scrub/Shrub. Wetland Classifications: LUW=Land Under Water, BVW = Bordering Vegetated Wetland, IVW = Isolated Vegetated Wetland, RA = Riverfront Area, BLSF = Bordering Land Subject to Flooding, ILSF = Isolated Land Subject to Flooding.

Streams and bordering wetlands along the right-of-way in Lakeville are part of the Taunton River and Buzzards Bay regional watersheds. The New Bedford Main Line segment of the right-of-way crosses a 1.5 mile segment of the Assonet Cedar Swamp. Pierce Brook and Cedar Swamp River flow through the Assonet Cedar Swamp; both join and ultimately flow to the Taunton River. An intermittent stream within Wetland LK-19 that crosses under the southern end of the New Bedford Main Line segment of the right-of-way and flows into Fall Brook is designated as an Outstanding Resource Water (ORW) because it discharges into Long Pond, a drinking water supply.

Three of the five stream crossings under the right-of-way in Lakeville are perennial. The Assonet River and Cedar Swamp River both flow under the New Bedford Main Line in Cedar Swamp (Wetlands LK 6 and LK 7). The Assonet River also flows under the Fall River Secondary segment (Wetlands LKF 1 and LKF 3) approximately 600 feet north of the Lakeville/Freetown town line. An intermittent stream has formed within the right-of-way south of Wetland LK 12.1 and Howland Road due to blocked drainage. This intermittent stream flows north into Wetland LK 12.1. A second intermittent stream has formed south of Wetland LK 17, again due to blocked drainage, and flows north into Wetland LK 17.

Freetown

In Freetown, the Stoughton alternative includes segments of both the New Bedford Main Line and the Fall River Secondary, both of which currently have active freight service. The New Bedford Main Line has approximately 3.6 miles of right-of-way, while the Fall River Secondary Line has approximately 5.5 miles of right-of-way, for a total of approximately 9.1 miles of right-of-way in Freetown.

Eighty wetlands are located along the right-of-way in Freetown. Thirty eight wetlands occur along the New Bedford Main Line, while 42 wetlands occur along the Fall River Secondary. The wetlands in Freetown include extensive forested areas dominated by red maple swamps and four perennial streams. An ANRAD was submitted to the Freetown Conservation Commission in June 2011. The Commission issued an ORAD on January 23, 2012. The Freetown Station was excluded from the ORAD.

Table 4.16-16 lists the wetlands delineated along the New Bedford Main Line segment of the right-of-way in Freetown and the resources associated with each wetland. Table 4.16-17 lists the wetlands delineated along the Fall River Secondary segment of the right-of-way in Freetown and the resources associated with each wetland.

Streams and bordering wetlands along the New Bedford Main Line in Freetown are part of the Buzzards Bay regional watershed, while streams and bordering wetlands along the Fall River Secondary are part of the Taunton River regional watershed. Perennial streams in the Taunton River watershed include Terry Brook and Rattlesnake Brook. Wetlands FRF 11 and FRF 12 comprise Terry Brook Pond, which lies on both sides of the right-of-way, north of Copicut Road on the Fall River Secondary. Bordering wetlands along this segment also flow into the Assonet River before discharging into the Taunton River. Three of

the 14 streams bridged by the Fall River Secondary in Freetown [Fall Brook (Wetlands FRN 11 and FRN 13), Rattlesnake Brook (Wetland FRN 15), and an unnamed stream (Wetland FRF 26A)] are perennial. The Freetown Conservation Commission did not confirm BVW at the wetlands associated with the proposed station (Wetlands 1 through 6), but these wetlands are included in the table for informational purposes.

New Bedford

The New Bedford segment of the Stoughton alternative is approximately 7.0 miles long and has active freight service along the New Bedford Main Line. Thirty-three wetlands are located along the right-of-way in New Bedford, three of which are isolated. The wetlands in New Bedford include extensive forested areas dominated by red maple and Atlantic white cedar swamps, and highly disturbed systems dominated by common reed (*Phragmites australis*) and other invasive plant species. An ANRAD was submitted to the New Bedford Conservation Commission in April 2011. The Commission issued an ORAD on July 12, 2011. Table 4.16-18 lists the wetlands delineated along the right-of-way in New Bedford and the resources associated with each wetland.

Streams and wetlands along the right-of-way in New Bedford are part of the Buzzards Bay regional watershed. The right-of-way in New Bedford crosses three stream channels, all of which are intermittent. Wetlands NB-21 and NB-22 are part of the Acushnet Cedar Swamp State Reservation, a Massachusetts State Park as well as a National Natural Landmark designated by the National Park Service.

2 Shading denotes ORW.

Fall River

The Fall River segment of the Stoughton alternative is approximately 5.3 miles long and has active freight service along the Fall River Secondary. This segment of the right-of-way passes through high density residential, commercial, and industrial areas. Seventeen wetlands are located along the right-of-way in Fall River, one of which is an isolated federal wetland. The wetlands in Fall River include disturbed systems dominated by common reed and other invasive species, and one perennial stream. An ANRAD was submitted to the Fall River Conservation Commission in May 2011. The Commission issued an ORAD on July 12, 2011. Table 4.16-19 lists the wetlands delineated along the right-of-way in Fall River and the resources associated with each wetland.

2 Not field delineated. Approximate limit of Bank retrieved from the MassGIS wetlands data layer.

Fall River is the only municipality along the South Coast Rail project corridor that has coastal wetland resource areas (five areas of Land Subject to Coastal Storm Flowage and four areas of Coastal Bank). Streams and bordering wetlands along the right-of-way in Fall River are part of the Narragansett Bay

regional watershed. All wetlands along the right-of-way in Fall River discharge into the Taunton River. Areas of the Taunton River along the right-of-way were delineated using ordinary high water lines.

Summary

Stoughton Alternative

The South Coast Rail project corridor for the Stoughton Alternative contains 276 Bordering Vegetated Wetlands, 52 additional Isolated Vegetated Wetlands, and two areas of Isolated Land Subject to Flooding within or directly adjacent to the right-of-way. These 329 vegetated wetlands are subject to jurisdiction under Sections 404 and 401 of the Federal Clean Water Act. In addition, the Stoughton Alternative crosses (or is within Riverfront Area of) 52 perennial streams or rivers, and is within the 100 year floodplain in 69 locations. There are 70 waterbodies (perennial streams and ponds) along the South Coast Rail project corridor. A total of 136 areas of Bank (which include banks of perennial as well as intermittent streams, ponds, and any other waterbody) are present along the project corridor. Table 4.16-20 provides a summary of the number of different wetland resource types along the right-of-way, by municipality and in total.

Table 4.16-20 Summary of Existing Conditions (Stoughton Alternative)

Municipality	Total Delineated Areas[1]	Bank	LUW	BVW	IVW	RA	BLSF[2]	ILSF[2]	Coastal Bank	LSCSF
Canton	10	4	4	6	4	2	5	0	0	0

1 Delineated areas may qualify as more than one type of wetland resource area.
Wetland Classifications: LUW=Land Under Water, BVW = Bordering Vegetated Wetland, IVW = Isolated Vegetated Wetland, RA = Riverfront Area, BLSF = Bordering Land Subject to Flooding, LSCSF = Land Subject to Coastal Storm Flowage, ILSF = Isolated Land Subject to Flooding.
2 BLSF and ILSF were withdrawn from the ANRAD applications for the municipalities of Stoughton and Easton, and therefore neither resource area was confirmed by the Conservation Commissions from either municipality.

Whittenton Alternative

There are four wetland areas along the right-of-way of the Whittenton Branch in Raynham, and 13 wetland areas along the right-of-way of the Whittenton Branch in Taunton, plus one additional isolated wetland along the Attleboro Secondary that was identified using available information. All of these 18 wetlands are considered Waters of the United States, while 13 wetlands are considered state jurisdictional. The Whittenton Branch includes one perennial stream crossing and six intermittent stream crossings. All the streams and wetlands along the Whittenton Branch are in the Taunton River regional watershed. The South Coast Rail project corridor for the Whittenton Alternative as a whole

contains 351 total delineated wetland areas. Table 4.16-21 provides a summary of the number of different wetland resource types along the right-of-way of the Whittenton Alternative, by municipality and in total.

Table 4.16-21 Summary of Existing Conditions (Whittenton Alternative)

4.16.9 Analysis of Impacts

4.16.9.1 Introduction

Section 4.16.8 - Existing Conditions above identified the wetlands near each of the proposed station sites, layover facilities sites and railroad corridors associated with the South Coast Rail project alternatives. Section 4.16.9 (this section) identifies the impacts to wetland resources that may result from implementing each of the proposed South Coast Rail alternatives (inclusive of railroad alignments, train stations, and layover facilities).

Wetland resources are protected under several state and federal regulatory programs, including Section 404 of the (federal) Clean Water Act, the Massachusetts Clean Waters Act (MGL Chapter 21, §26-53) and the Massachusetts Wetlands Protection Act (310 CMR 10.00). Issues specific to Stormwater Management are addressed in Chapter 4.17, *Water Resources*; however, certain wetlands are protected and subject to higher standards of treatment prior to discharge. The alternatives discussed in this chapter are exempt from Local Wetland Bylaws as the project is a state transportation project.[32]

This section discusses environmental consequences as they relate to the proposed alternatives for the South Coast Rail project as well as historical impacts and reasonably foreseeable future impacts that help in the design and selection of mitigation for direct wetland impacts.

[32] MassDOT Interoffice Memorandum from M. Conyngham General Council to K. Walsh Director of Environmental Services dated May 2, 2011.

Some waterways are also regulated under MGL Chapter 91, which protects the public interest in tidelands, Great Ponds, and non-tidal rivers. More detail on compliance with regulations protecting coastal resources is provided in Chapter 4.18, *Coastal Zone Consistency and Chapter 91 – Compliance*. Potential impacts to ground and surface drinking water supplies, water supply protection districts, and stormwater management are discussed in Chapter 4.17, *Water Resources*. Important wetland wildlife habitat, such as vernal pools and Atlantic white cedar swamps would also be impacted by the South Coast Rail project. More detail on these resources is provided in Chapter 4.14, *Biodiversity, Wildlife and Vegetation*. Cumulative impacts to wetlands are discussed in Chapter 5, *Indirect Effects and Cumulative Impacts*.

Wetland impacts are described quantitatively by specific wetland resources as well as qualitatively by functions and values. These direct and indirect impacts are discussed along with potential mitigation efforts and how they relate to the state and federal regulatory process. The direct and indirect assessment methodologies are discussed in Section 4.16.7. Section 4.16.9.2 identifies direct impacts, Section 14.16.9.3 identifies indirect impacts, Section 4.16.9.4 identifies general temporary construction period impact, and Section 4.16.9.5 summarizes the impacts by alternative. Section 4.16.10 presents mitigation approaches, and Section 4.16.11 discusses compliance with wetland regulations and the need for the Commissioner of MA DEP to issue a Variance for impacts associated with Bordering Vegetated Wetlands (BVW) and other resource areas.

4.16.9.2 Direct Impacts

This section evaluates the potential impacts to wetlands associated with the project alternatives that are being advanced for consideration. These alternatives include the No-Build Alternative (Enhanced Bus), the Stoughton Alternatives (Electric and Diesel), and the Whittenton Alternatives (Electric and Diesel). The alternatives considered would include the construction or rehabilitation of new railroads, stations, and layover facilities. Figure 1.4-1 shows the route for each alternative. The results of the analysis of direct wetland impacts along the South Coast Rail project alternatives are presented below. The direct impacts to wetland resource areas along the right-of-way are discussed. Direct impacts were calculated separately for federal vs. state jurisdictional resources, and area was tabulated by municipality, cover type, and watershed. The impacts presented include portions of the rail lines within the southern part of the South Coast Rail study area that are common to both rail alternatives, as well as any impacts associated with station improvements.

Using the methods of analysis previously described, permanent and temporary direct impacts were calculated to state wetland/aquatic resource areas in each municipality along the right-of-way:

- Bank;
- Bordering Vegetated Wetlands (BVW);
- Land Under Water (LUW);
- Bordering Land Subject to Flooding (BLSF);
- Isolated Land Subject to Flooding (ILSF);
- Riverfront Area (RA);

- Land Subject to Coastal Storm Flowage (LSCSF); and
- Coastal Bank.

The direct (permanent and temporary) impacts to the wetlands in each municipality are presented below.

Figures 4.16-2a-q, 4.16-3a-q, 4.16-4a-j, and 4.16-5a-e show the locations of all direct wetland impacts, as well as the functions and values provided by each wetland. For a more detailed view of existing wetlands within or adjacent to proposed station locations and layover facilities see Chapter 4.17, *Water Resources*.

No-Build (Enhanced Bus) Alternative

The No-Build Alternative would consist of enhancing current bus service along existing roads and highways. Three existing park-and-ride facilities would be modified as part of the No-Build Alternative:

- The West Bridgewater Park-and-Ride lot is located near the southwest corner of the intersection of Routes 106 and 24;
- The Mount Pleasant Street Park-and-Ride lot is located on the northwest corner of the intersection of King's Highway and Route 140 in New Bedford;
- The Silver City Galleria Park-and-Ride lot is located adjacent to the Silver City Galleria shopping mall in Taunton.

None of the park-and-ride facilities contains wetland resources nor would the proposed modifications be expected to impact wetland resources.

Stoughton Electric Alternative

The Stoughton Electric Alternative alignment would be comprised of a portion of the Northeast Corridor and the Stoughton Line (north of Weir Junction where it joins the New Bedford Main Line). This alternative would use the Northeast Corridor from South Station to Canton Junction, and the existing Stoughton Line from Canton Junction to the relocated Stoughton Station (Figures 4.16-2a-b). From that point, commuter rail service would be extended, using an out-of-service rail bed, south through Raynham Junction to Weir Junction in Taunton, where it would join the northern end of the Southern Triangle (Figures 4.16-b-q). The Southern Triangle portion of the project is common to the Stoughton and Whittenton alternatives and requires the rail bed, track, and signals along the existing Fall River Secondary and New Bedford Main Lines to be upgraded for passenger rail traffic. This portion of the project extends from Weir Junction in Taunton along the New Bedford Main Line through Berkley, Lakeville, Freetown, and New Bedford and along the Fall River Secondary from Myricks Junction in Lakeville through Freetown and Fall River (Figures 4.16-3a-q and 4.16-4a-j).

This alternative would include Battleship Cove Station, Canton Center Station, Canton Junction Station, Easton Village Station, Fall River Depot Station, Freetown Station, King's Highway Station, North Easton Station, Raynham Park Station, Stoughton Station, Taunton Station, Taunton Depot Station, and Whale's Tooth Station. Three existing train stations along the Stoughton Line would be reconstructed (Canton Center Station, Canton Junction Station, and Stoughton Station). Stoughton Station would be relocated to eliminate conflicts with traffic in Stoughton Center and to support downtown revitalization efforts.

Four new train stations would be constructed along this alignment (North Easton Station, Easton Village Station, Raynham Park Station, and Taunton Station). The alternative includes two layover facilities (Weaver's Cove East on the Fall River Secondary and Wamsutta on the New Bedford Main Line). Potential impacts to wetland resources resulting from developing the new stations and layover facilities are inclusive and not discussed separately.

No construction would be required along the Northeast Corridor. The existing Stoughton Line commuter rail track from Canton Junction to Stoughton would be upgraded for the Stoughton Electric Alternative. New track would be installed on the existing embankment from Stoughton south to Weir Junction. A section from Foundry Street in Easton to Raynham Station through the Hockomock Swamp would be constructed on an elevated trestle (Figures 4.16-2k-l). Canopy clearing would be required along the right-of-way where the elevated trestle would be located within the Hockomock Swamp, so as to accommodate additional height requirements associated with the trestle. Canopy clearing generally occurs within upland forest along the existing railroad grade, although portions would occur in wetland resources. Canopy clearing would not result in additional discharge of fill material into wetland resources as this work would occur from uplands (i.e., the existing railroad grade), without the necessity of temporary construction areas in wetlands. All canopy clearing in wetlands is accounted for in the 4-foot zone of temporary impact beyond the toe of slope. No work, or vegetation removal, would take place outside of the proposed limit of work. The amount of upland forest habitat impact was also calculated based on the limit of work line, which includes the zone of temporary impacts.

The alignment of the proposed Stoughton Alternative follows a previously developed railroad corridor. Although the rail corridor has been established, necessary track improvements would result in the loss of wetland resources along the right-of-way. The following sections describe both direct and indirect impacts as they relate to this alternative.

Direct Impact to State and Federal Resource Areas by Municipality

In addition to state resource areas, this section quantifies and discusses the federal waters of the United States. These wetlands are assumed jurisdictional under Section 404 of the Clean Water Act. These wetlands are also regulated at the state level by 314 CMR 9.00, which implements the federal Section 401 Water Quality Certification program for a discharge of dredged or fill material.

For the purposes of this assessment, waters of the United States are described as either waterbodies/waterways (WW) or vegetated wetlands (VW). The Section 404(b)(1) guidelines consider wetlands to be special aquatic sites. Using the analysis methods described previously, direct impacts (both permanent and temporary) were calculated to federal waters of the United States (including wetlands) in each municipality. Impacts were totaled for each municipality as a whole. The direct impacts to federal wetlands in each municipality are presented below. Although some small wetlands within the project corridor are isolated–i.e., they are not adjacent to any traditional navigable waters or tributaries thereto–the applicant is not asserting that these wetlands do not have a significant nexus to traditional navigable water. Therefore these wetlands are assumed to be jurisdictional waters of the United States under Section 404. The numbers of impacted waters/wetlands and the total size of the impact for each type of resource area are given for each municipality.

Canton—The Canton segment of the Stoughton alternative is approximately 2.3 miles long and is an active commuter and freight service on the Stoughton Line. Reconstructing the existing active rail line in Canton would result in permanent and temporary impact to BVW in two wetlands, with 1,200 square

feet (sf) (<0.1 acre) of permanent impact and 1,436 sf (<0.1 acre) of temporary impact, for a total of 2,636 sf (0.1 acre) of alteration to BVW. Bank would be permanently impacted in two locations, with a total of 90 linear feet (lf) impact. LUW would be temporarily impacted in one wetland, with a total of 229 sf (<0.1 acre) of impact. BLSF would be permanently impacted in five locations, with a total of 40,079 sf (0.9 acre) of impact. RA would be permanently impacted in one location, with a total of 17,257 sf (0.4 acre) of new development. Direct wetland impacts to BLSF and RA in Canton are primarily associated with Beaver Meadow Brook (Wetland CA 2.1). A small amount (less than 0.1 acre) of BVW fill would also occur in this wetland.

Reconstructing the existing active rail line in Canton for the South Coast Rail project would result in permanent impact to two VWs, with a total of 1,200 square feet (sf) (<0.1 acre) of permanent impact, and temporary impact to four VWs, with a total of 2,049 sf (<0.1 acre) of temporary impact. One WW would be temporarily impacted, with a total of 229 sf (0.1 acre) of temporary impact. Direct impacts in Canton would be mainly limited to VW impacts associated with Wetland CA 2.1, Beaver Meadow Brook. Table 4.16-22 lists the impacted wetlands in Canton and the size of each impacted area.

Stoughton—The Stoughton segment of the Stoughton alternative is approximately 4.2 miles long and contains active and inactive sections of the Stoughton Line. Reconstructing the existing active and inactive rail line in Stoughton would result in permanent impact to BVW in six wetlands, with 86,974 sf (2.0 acres) of impact, and temporary impact to BVW in five wetlands, with 6,198 sf (0.1 acre) of impact, for a total of 93,172 sf (2.1 acres) of alteration to BVW. Bank would be permanently impacted in three locations, with a total of 539 lf of impact. LUW would not be impacted. BLSF would be permanently impacted in one location, with a total of 32,008 sf (0.7 acre) of impact. RA would not be impacted.

The 2.0 acres of BVW fill in Stoughton is the largest amount in any municipality. Most of this fill (1.9 acres) is associated with Wetlands ST 6A and ST 7. The fill to Wetland ST 7 is the single largest area of BVW fill associated with the project and would result from constructing the new frontage road south of Morton Street. Additional direct wetland impacts in Stoughton would include approximately 470 lf of Bank associated with Wetland ST 7A, a small intermittent stream channel that flows within the right-of-way south from Wetland ST 6A (100 series). No state jurisdictional wetland impacts would occur in Stoughton from constructing the North Easton Station. The new frontage road would affect approximately 0.7 acre of BLSF.

Notes: Wetland Classifications: BVW = Bordering Vegetated Wetland, LUW=Land Under Water, BLSF = Bordering Land Subject to Flooding, ILSF = Isolated Land Subject to Flooding, RA = Riverfront Area.

Reconstructing the existing active and inactive rail line in Stoughton would result in permanent impact to eight VWs, with a total of 90,729 sf (2.1 acres) of impact, and temporary impact to six VWs, with a total of 6,504 sf (0.1 acre) of impact. No WW impacts would occur. The 2.1 acres of fill to VWs in Stoughton is the largest amount that would occur in any municipality. Most of this fill (1.9 acres) is associated with Wetlands ST 6A and ST 7 and would result from constructing the new frontage road south of Morton Street. One VW, Wetland ST 149.3, would be filled to construct the North Easton Station. Table 4.16-23 lists the impacted wetlands in Stoughton and the size of each impacted area.

Easton—The Easton segment of the Stoughton alternative is approximately 7.1 miles long and is an inactive portion of the Stoughton Line. Reconstructing the existing inactive rail line in Easton would result in permanent impact to BVW in nine wetlands, with 14,828 sf (0.3 acre) of impact, and temporary impact to BVW in 13 wetlands, with 8,719 sf (0.2 acre) of impact, for a total of 23,547 sf (0.5 acre) of alteration to BVW. Bank would be permanently impacted in four locations, with a total of 5,423 lf of impact. LUW would not be impacted. BLSF would be permanently impacted in two locations, with a total of 36,526 sf (0.8 acre) of impact. RA would be permanently impacted in four locations, with a total of 35,715 sf (0.8 acre) of new development.

Unavoidable direct impacts to BLSF and RA would be primarily associated with Whitman Brook (Wetland EA 5), Black Brook (Wetlands EA 92.1 and 91), and Queset Brook (Wetland 2), all of which cross the right-of-way. Wetland EA 92.1 also has 0.8 acre of BLSF associated with it. An intermittent stream has formed within the right-of-way upgradient of Wetland EA 96 due to blocked drainage ditches; relocating this channel would result in 5,350 lf of bank impact. Additional direct wetland impacts in Easton would include 0.3 acre of BVW fill. The majority (0.2 acre) of this fill occurs in Wetland EA 12.1, a narrow wetland area that has formed within the right-of-way. No direct impacts would occur in the Hockomock Swamp because the tracks would be on an elevated trestle.

Constructing the North Easton Station would permanently impact 319 sf (<0.1 acre) of BVW in Wetland EA 1 (100). Constructing the Easton Village Station would permanently impact 1,552 sf (<0.1 acre) of BLSF in Wetland 101 and 5,749 sf (0.1 acre) of RA in Wetland 2. Both wetlands are associated with Queset Brook.

Reconstructing the existing inactive rail line in Easton would result in permanent impact to 11 VWs, with a total of 18,134 sf (0.4 acre) of impact, and temporary impact to 15 VWs, with a total of 9,265 sf (0.2 acre) of impact. No WW impacts would occur. Direct impacts in Easton would include 0.4 acre of fill to VWs. The majority (0.2 acre) of this fill occurs in Wetland EA 12.1, a narrow wetland area that has formed within the right-of-way. Other direct impacts are to six areas that have been designated as certified vernal pools along the right-of-way. No direct impacts would occur in the Hockomock Swamp because the tracks would be on an elevated trestle. Constructing the North Easton Station would permanently impact 319 sf (<0.1 acre) of VW in Wetland EA 1 (100). No federal resource areas would be impacted from constructing the Easton Village Station. Table 4.16-24 lists the impacted wetlands in Easton and the size of each impacted area.

Notes: Wetland Classifications: BVW = Bordering Vegetated Wetland, LUW=Land Under Water, BLSF = Bordering Land Subject to Flooding, ILSF = Isolated Land Subject to Flooding, RA = Riverfront Area.

1 BLSF and ILSF were withdrawn from the ANRAD application for the municipality of Easton, and therefore neither resource area was confirmed by the Conservation Commission. Information for these resource areas is approximate.

Raynham—The Raynham segment of the Stoughton alternative is approximately 4.9 miles long and is an inactive portion of the Stoughton Line. Reconstructing the existing inactive rail line in Raynham would result in permanent impact to BVW in 17 wetlands, with 58,628 sf (1.3 acres) of impact, and temporary impact to BVW in 21 wetlands, with 41,403 sf (0.9 acre) of impact for a total of 100,031 sf (2.3 acres) of alteration to BVW. Bank would be permanently impacted in eight locations, with a total of 6,994 lf of impact. LUW would be permanently impacted in two wetlands, with a total of 66,528 sf (1.5 acres) of impact, and temporarily impacted in four wetlands, with a total of 3,639 sf (0.1 acre) of impact. BLSF would be permanently impacted in three locations, with a total of 126,940 sf (2.9 acres) of impact. RA would be permanently impacted in three locations, with a total of 110,368 sf (2.5 acres) of new development.

Raynham has some of the largest direct wetland impacts along the project corridor. Blocked drainage ditches have forced water to travel down the right-of-way, which has formed a perennial stream (Wetland R 62.1). Relocating this stream to one side of the right-of-way would create impacts to over 6,500 lf of Bank, 204 sf of BVW, 1.5 acres of LUW, and 2.3 acres of RA to reconstruct the railroad and to construct Raynham Park Station. Additional direct wetland impacts in Raynham would include 77 lf of Bank impact, 18,578 sf (0.4 acre) of BVW impact, and 76,126 sf (1.7 acres) of BLSF to Wetlands R 12.2 and R 12.1 (300), at Pine Swamp Brook, in the Pine Swamp area.

Reconstructing the existing inactive rail line in Raynham would result in permanent impact to 17 VWs, with a total of 58,628 sf (1.3 acres) of impact, and temporary impact to 21 VWs, with a total of 41,403 sf (1.0 acre) of impact. Two WW areas would be permanently impacted, with a total of 66,528 sf (1.5 acres) of impact, and four WW areas would be temporarily impacted, with a total of 3,639 sf (0.1 acre) of impact.

Raynham would have some of the largest direct wetland impacts along the project corridor. Blocked drainage ditches have forced water to travel down the right-of-way and formed a perennial stream (Wetland R 62.1). Relocating this stream to one side of the right-of-way would create impacts to 204 sf of VW and over 1.5 acres of WW to reconstruct the railroad and to construct Raynham Park Station. Additional direct impacts in Raynham would include fill to VWs in Wetlands R 12.2 and R 12.1 (0.4 acre) in Pine Swamp. Table 4.16-25 lists the impacted wetlands in Raynham and the size of each impacted area.

In response to comments on the DEIS/DEIR the feasibility of constructing a trestle through Pine Swamp was evaluated. The current design for the Stoughton Alternative includes an at-grade track structure through the Pine Swamp, utilizing the existing embankment to carry the proposed track. A trestle option similar to the structure proposed for the Hockomock Swamp was evaluated but was found to be not practicable based on cost and logistics.

Notes: Wetland Classifications: BVW = Bordering Vegetated Wetland, LUW=Land Under Water, BLSF = Bordering Land Subject to Flooding, ILSF = Isolated Land Subject to Flooding, RA = Riverfront Area.

Pine Swamp is a 275-acre wetland system located in western Raynham and consisting of several properties that are owned by the Town of Raynham Conservation Commission. The Stoughton Line crosses the swamp in a one-mile segment from King Phillip Street to East Britannia Street (Figures 4.16-1o and p). This area consists of forested and marsh wetlands known as Pine Swamp, an area that is located within estimated habitat of rare wetlands species, and which supports an Atlantic white cedar swamp community. Pine Swamp is currently fragmented by the former railroad bed, which acts as a barrier to aquatic organisms except at the two culverts. The swamp is also fragmented by the Taunton Municipal Light Corporation's overhead power line that is maintained as a cleared utility corridor parallel to the existing railroad embankment. The Taunton Municipal Light Corporation (TMLC) currently uses the embankment as access for maintenance of their overhead wires. With the proposed new rail in place, they would be required to use a high-rail vehicle to perform this function. A separate access road is not required and will not be constructed.

Pine Swamp is a small (relative to the Hockomock) wetland ecosystem that is not recognized as an ACEC or Important Bird Area. It does not have extensive vernal pool complexes adjacent to the existing elevated embankment or track bed, and does not support state-listed salamanders or turtles. The only state-listed species present is a butterfly (Hessel's hairstreak). The area immediately adjacent to the existing embankment is a power line where invasive species including common reed have become established.

The currently proposed At-Grade design would cost approximately $5 Million, and would result in permanent BVW impacts of approximately 18,600 square feet of wetland. Wildlife passage would be provided by reconstructing the two existing stream crossings with extended culverts (which provide a shelf or bank on either side of the waterway to allow a passage for non-aquatic wildlife), and by adding at least four wildlife underpasses. These wildlife underpasses will maintain travel passages for species that may be unable to cross the tracks (salamanders, frogs, turtles, small mammals) as well as enhance travel passages for small mammals that may be deterred from crossing an active rail line. Drift fences will be installed that will facilitate wildlife passage by directing movement to these underpasses.

A trestle structure, similar to the structure proposed for the Hockomock Swamp, would consist of two distinct cross sections – a 1,000-foot transition at each end and a central trestle structure, approximately 3,300 feet long. The transition would include a cast-in-place (CIP) retained fill section that would vertically transition from the standard at-grade track cross section to the trestle at a grade of one percent. The retained fill section has would have an overall width of 28 to 30 feet. The cast-in-place retaining walls would maintain a vertical barrier along each side of the track to minimize wetland impacts as the track profile rose up to the level of the trestle. The trestle would consist of a prestressed concrete superstructure. The overall width of the superstructure would be 21 feet, supported on pile caps spaced every 30 feet. The bottom of the superstructure would be approximately three feet above the existing track bed to allow for inspection and maintenance, which translates to the top of rail profile rising up above the existing embankment as much as 9.5 feet. This solution reduces wetland impacts to only those locations where the pier caps and transition retaining walls extend into the bordering vegetated wetlands.

The Trestle Option would cost approximately $50 Million, which includes engineering and construction costs. Other alternatives may be considered beyond the common bridge types, however it is not anticipated that any savings would be significant enough to make the trestle a viable option. This option would result in filling approximately 3,800 square feet of wetland.

Because Pine Swamp does not provide extraordinary biodiversity values, a trestle would not provide significant biodiversity or rare species benefits. The cost increase (ten times the cost of the At-Grade Alternative) is not warranted and the trestle is not practicable based on cost. Proposed wildlife crossing structures would mitigate for the effects of reconstructing the At-Grade Option, and the proposed Mechanically Stabilized Earth MSE retaining walls would minimize wetland impacts.

Taunton—In Taunton, the Stoughton alternative includes segments of both the Stoughton Line and the New Bedford Main Line. The New Bedford Main Line segment extends from Weir Junction to Cotley Junction. The two segments form one continuous track through Taunton approximately 4.7 miles long. Reconstructing the existing active and inactive rail lines in Taunton would result in permanent impact to BVW in 20 wetlands, with 63,313 sf (1.5 acres) of impact, and temporary impact to BVW in 24 wetlands, with 55,795 sf (1.3 acres) of impact, for a total of 119,108 sf (2.7 acres) of alteration to BVW. Bank would be permanently impacted in four locations, with a total of 468 lf of impact. LUW would be temporarily impacted in one wetland, with a total of 1,067 sf (<0.1 acre) of impact. BLSF would be permanently impacted in six locations, with a total of 33,290 sf (0.8 acre) of impact. RA would be permanently impacted in four locations, with a total of 55,523 sf (1.3 acres) of new development.

Taunton has some of the largest direct wetland impacts along the project corridor. Several wetlands have formed partially or mostly within the inactive right-of-way and would be impacted. Additional direct wetland impacts in Taunton would include 0.7 acre of RA and 0.5 acre of BLSF associated with the Taunton River (Wetlands TCM 1.2 and TR (Crossing 2)).

Reconstructing the existing active and inactive rail line in Taunton would result in permanent impact to 24 VWs, with a total of 83,685 sf (1.9 acres) of impact, and temporary impact to 27 VWs, with a total of 58,790 sf (1.3 acres) of impact. One WW would be temporarily impacted, with a total 1,067 sf (<0.1 acre) of impact. Taunton would have some of the largest direct wetland impacts along the project corridor. Several wetlands have formed partially or mostly within the inactive right-of-way and would be impacted. Table 4.16-26 lists the impacted wetlands in Taunton and the size of each impacted area.

Notes: Wetland Classifications: BVW = Bordering Vegetated Wetland, LUW=Land Under Water, BLSF = Bordering Land Subject to Flooding, ILSF = Isolated Land Subject to Flooding, RA = Riverfront Area.

Berkley—In Berkley, the Stoughton alternative includes segments of both the New Bedford Main Line and the Fall River Secondary, both of which currently have active freight service. The New Bedford Main Line has approximately 2.9 miles of right-of-way, while the Fall River Secondary Line has approximately 0.8 mile of right-of-way, for a total of approximately 3.7 miles of right-of-way in Berkley.

Reconstructing the existing active rail lines in Berkley would result in permanent impact to BVW in 14 wetlands, with 61,247 sf (1.4 acres) of impact, and temporary impact to BVW in 19 wetlands, with 42,056 sf (1.0 acre) of impact, for a total of 103,303 sf (2.4 acres) of alteration to BVW. Bank would be permanently impacted in two locations, with a total of 233 lf of impact. LUW would not be impacted. BLSF would be permanently impacted in two locations, with a total of 7,325 sf (0.2 acre) of impact. RA would be permanently impacted in four locations, with a total of 48,648 sf (1.1 acres) of new development.

The largest direct wetland impacts in Berkley are those associated with the Cotley River, which is bridged twice along the project corridor and also flows directly adjacent to the right-of-way for several hundred feet. Reconstructing the rail line would require widening the existing berm, impacting wetlands associated with the river. Direct wetland impacts associated with the Cotley River would include 1.0 acre of RA and 0.7 acre of BVW fill to four wetland areas (Wetlands BCKM 4 (100), BKCM 10 (200), BKCM 4 (400), and BKCM 18).

Reconstructing the existing active rail lines in Berkley would result in permanent impact to 14 VWs, with a total of 65,402 sf (1.5 acres) of impact, and temporary impact to 18 VWs, with a total of 42,057 sf (1.0 acre) of impact. No WW impacts would occur. The largest direct impacts in Berkley are in vegetated wetlands associated with the Cotley River, which is bridged by the tracks twice along the project corridor and also flows directly adjacent to the right-of-way for several hundred feet. Reconstructing the rail line would require widening the existing berm, causing impacts to wetlands associated with the river. Direct impacts associated with the Cotley River include 0.7 acre of fill to four VWs (Wetlands BCKM 4 (100), BKCM 10 (200), BKCM 4 (400), and BKCM 18). Table 4.16-27 lists the impacted wetlands in Berkley and the size of each impacted area.

Lakeville—In Lakeville, the Stoughton alternative includes segments of both the New Bedford Main Line and the Fall River Secondary, both of which currently have active freight service. The New Bedford Main Line has approximately 3.5 miles of right-of-way, while the Fall River Secondary has approximately 0.3 mile of right-of-way, for a total of approximately 3.8 miles of right-of-way in Lakeville.

Reconstructing the existing active rail lines in Lakeville would result in permanent impact to BVW in 10 wetlands, with 34,442 sf (0.8 acre) of impact, and temporary impact to BVW in nine wetlands, with 23,382 sf (0.5 acre) of impact, for a total of 57,824 sf (1.3 acres) of alteration to BVW. Bank would be permanently impacted in three locations, with a total of 606 lf of impact. LUW would be temporarily impacted in one wetland, with a total of 829 sf (<0.1 acre) of impact. BLSF would be permanently impacted in one location, with a total of 2,623 sf (0.1 acre) of impact. RA would be permanently impacted in two locations, with a total of 33,439 sf (0.8 acre) of new development.

The largest direct wetland impacts in Lakeville are those associated with the Assonet Cedar Swamp area and the Cedar Swamp River. Wetland LK 7 would receive 0.5 acre of BVW fill and 0.6 acre of RA impact. Additional direct wetland impacts in Lakeville would include 0.2 acre of BVW fill to nine other wetland areas on the New Bedford Main Line and Fall River Secondary.

Reconstructing the existing active rail lines in Lakeville would result in permanent impact to 11 VWs, with a total of 34,563 sf (0.8 acre) of impact, and temporary impact to 10 VWs, with a total of 23,622 sf (0.5 acre) of impact. One WW would be temporarily impacted, with a total of 829 sf (<0.1 acre) of impact. The largest direct impacts in Lakeville would be in wetlands associated with the Assonet Cedar Swamp and the Cedar Swamp River. Wetland LK 7 would receive 0.5 acre of fill. Additional direct impacts in Lakeville would include 0.2 acre of fill to nine other VWs along the New Bedford Main Line and Fall River Secondary. Table 4.16-28 lists the impacted wetlands in Lakeville and the size of each impacted area.

Notes: Wetland Classifications: BVW = Bordering Vegetated Wetland, LUW=Land Under Water, BLSF = Bordering Land Subject to Flooding, ILSF = Isolated Land Subject to Flooding, RA = Riverfront Area.

Freetown—In Freetown, the Stoughton alternative includes segments of both the New Bedford Main Line and the Fall River Secondary, both of which currently have active freight service. The New Bedford Main Line has approximately 3.6 miles of right-of-way, while the Fall River Secondary Line has approximately 5.5 miles of right-of-way, for a total of approximately 9.1 miles of right-of-way in Freetown.

Reconstructing the existing active rail lines in Freetown would result in permanent impact to BVW in 17 wetlands, with 43,869 sf (1.0 acres) of impact, and temporary impact to BVW in 27 wetlands, with 24,465 sf (0.6 acre) of impact, for a total of 68,334 sf (1.6 acres) of alteration to BVW. Bank would be permanently impacted in 20 locations, with a total of 2,460 lf of impact. LUW would be permanently and temporarily impacted in two wetlands, with a total of 14,072 sf (0.3 acre) of permanent impact and 6,379 sf (0.1 acre) of temporary impact. BLSF would be permanently impacted in 11 locations, with a total of 12,435 sf (0.3 acre) of impact. RA would be permanently impacted in four locations, with a total of 42,223 sf (1.0 acre) of new development.

Direct wetland impacts in Freetown include four areas of BVW fill greater than 0.1 acre along the Fall River Secondary, including 0.3 acre of BVW fill to Wetland FRF 21, a wetland that has formed within the right-of-way. Impact to 0.5 acre of RA and 0.2 acre of BVW fill would occur to two wetland areas associated with the Cedar Swamp River (Wetlands FRF 2 and FRF 3 (100 series)). Reconstructing the rail bed would affect 1,592 lf of Bank impact as well as 0.3 acre of LUW fill to Wetlands FRF 11 and FRF 12, associated with Terry Brook Pond on both sides of the right-of-way (Fall River Secondary). One BVW (Wetland RFR-23.1.1) would be directly impacted from constructing the Freetown Station.

Reconstructing the existing active rail lines in Freetown would result in permanent impact to 19 VWs, with a total of 47,935 sf (1.1 acres) of impact, and temporary impact to 30 VWs, with a total of 25,913 sf (0.6 acre) of impact. Two WW areas would be permanently and temporarily impacted, with a total of 14,072 sf (0.3 acre) of permanent impact and 6,379 sf (0.1 acre) of temporary impact.

Direct impacts in Freetown would include fill in four VWs in amounts greater than 0.1 acre along the Fall River Secondary, including 0.3 acre of fill in Wetland FRF 21, a wetland that has formed within the right-of-way, and 0.2 acre of fill in two VWs associated with the Cedar Swamp River (Wetlands FRF 2 and FRF 3 (100 series)). Constructing the Freetown Station would impact one VW (Wetland RFR-23.1.1), for a total of 2,590 sf of permanent impact, and 565 sf of temporary impact. Additional impacts in Freetown include 0.3 acre of WW fill in Wetlands FRF 11 and FRF 12, associated with Terry Brook Pond on both sides of the Fall River Secondary right-of-way. Table 4.16-29 lists the impacted wetlands in Freetown and the size of each impacted area.

Notes: Wetland Classifications: BVW = Bordering Vegetated Wetland, LUW=Land Under Water, BLSF = Bordering Land Subject to Flooding, ILSF = Isolated Land Subject to Flooding, RA = Riverfront Area.

New Bedford—The New Bedford segment of the Stoughton alternative is approximately 7.0 miles long and has active freight service along the New Bedford Main Line. Reconstructing the existing active rail line in New Bedford would result in permanent impact to BVW in 13 wetlands, with 53,137 sf (1.2 acres) of impact, and temporary impact to BVW in 14 wetlands, with 33,168 sf (0.8 acre) of impact, for a total of 86,305 sf (2.0 acre) of alteration to BVW. Bank would be permanently impacted in four locations, with a total of 269 lf of impact. LUW would not be impacted. BLSF would be permanently impacted in one location, with a total of 1,494 sf (<0.1 acre) of impact. RA would not be impacted.

Direct wetland impacts in New Bedford would include four areas of BVW fill greater than 0.1 acre, including 0.4 acre of BVW fill to Wetland NBS, a narrow wetland along the side of the railroad berm, which would be filled to construct the King's Highway Station. Other areas of BVW fill would occur in more natural wetland areas, including 0.3 acre of BVW fill to Wetland NB 28.

Reconstructing the existing active rail line in New Bedford would result in permanent impact to 15 VWs, with a total of 52,601 sf (1.2 acres) of impact, and temporary impact to 16 VWs, with a total of 33,370 sf (0.8 acre) of impact. No WW impacts would occur. Direct impacts in New Bedford would include four areas of fill in VWs in amounts greater than 0.1 acre, including 0.4 acre of fill in Wetland NBS, a narrow wetland (a former drainage ditch) within the right-of-way that would be filled to construct the King's Highway Station. Other areas of fill in VWs occur in more natural areas, including 0.3 acre of fill in Wetland NB 28. Table 4.16-30 lists the impacted wetlands in New Bedford and the size of each impacted area.

Fall River—The Fall River segment of the Stoughton alternative is approximately 5.3 miles long and has active freight service along the Fall River Secondary. Reconstructing the existing active rail line in Fall River would not result in any permanent impact to BVW, and temporary impact to BVW in one wetland, with 154 sf (<0.1 acre) of impact. Coastal Bank would be permanently impacted in four locations, with a total of 274 lf of impact. LUW would not be impacted. LSCSF would be permanently impacted in three locations, with a total of 25,221 sf (0.6 acre) of impact. RA would not be impacted.

Fall River is the only municipality along the project corridor that would have Coastal Bank and LSCSF impacts in three areas, including 0.4 acre of FA 6B). These impacts are associated with the Taunton River.

Reconstructing the existing active rail line in Fall River would result in permanent impact to two VWs, with a total of 1,647 sf (<0.1 acre) of impact, and temporary impact to three VWs, with a total of 2,192 sf (0.1 acre) of impact. No WW impacts would occur. Table 4.16-31 lists the impacted wetlands in Fall River and the size of each impacted area.

Notes: Wetland Classifications: BVW = Bordering Vegetated Wetland, LUW=Land Under Water, BLSF = Bordering Land Subject to Flooding, ILSF = Isolated Land Subject to Flooding, RA = Riverfront Area.

1 Riverfront Area is measured 25 feet from the edge of a resource area.

Summary of Direct Impacts to State and Federal Resource Areas—Reconstructing the existing active and inactive rail lines along the Stoughton alternative would result in permanent impact to BVW in 105 wetlands, with 9.6 acres of impact, and temporary impact to BVW in 131 wetlands, with 5.4 acres of impact, for a total of 15.0 acres of alteration to BVW. BVW impacts would result from reconstructing and widening existing berms associated with the rail lines, and filling wetlands that have formed within the right-of-way.

Bank would be permanently impacted in 46 locations, with a total of 16,813 lf of impact. The largest Bank impacts would occur in:

- Raynham (6,994 lf of impact), in order to relocate a perennial stream that has formed in the right-of-way due to blocked drainage ditches;
- Easton (5,423 lf of impact), due to an intermittent stream channel that flows down the right-of-way due to blocked drainage ditches; and
- Freetown (2,460 lf of impact), due to filling of Terry Brook Pond on both sides of the right-of-way.

LUW would be permanently impacted in four wetlands, with a total of 1.9 acres of impact, and temporarily impacted in nine wetlands, with a total of 0.3 acre of impact. LUW impacts would largely result mainly from relocating the perennial stream in Raynham and filling Terry Brook Pond in Freetown.

BLSF would be permanently impacted in 32 locations, with a total of 6.7 aces of impact. The largest BLSF impacts would occur in Raynham as a result of relocating the perennial stream.

RA would be permanently impacted in 22 locations, with a total of 7.9 acres of new development of naturally vegetated land outside of the existing ballast and other active rail elements. The largest RA impacts would occur in Raynham as a result of relocating the perennial stream.

Coastal Bank would be permanently impacted in four locations in Fall River, with a total of 274 lf of impact.

LSCSF would be permanently impacted in three locations in Fall River, with a total of 0.6 acre of impact, associated with the Taunton River.

Reconstructing the existing active and inactive rail lines along the project corridor would result in permanent impact to 121 VWs, with 10.4 acres of impact, and temporary impact to 148 VWs, with 5.6 acres of impact, for a total of 16.0 acres of alteration to VWs. Impacts to VWs would result from reconstructing and widening existing berms associated with the rail lines, and would impact wetlands that have formed within the right-of-way.

Four WW areas would be permanently impacted, with a total of 1.9 acres of impact, and nine WW areas would be temporarily impacted, with a total of 0.3 acre of impact. WW impacts would result mainly from relocating a perennial stream that has formed within the right-of-way in Raynham due to blocked drainage culverts, and filling portions of Terry Brook Pond in Freetown on both sides of the right-of-way in order to widen the existing berm.

Table 4.16-32 summarizes the direct impacts to state and federal wetland resource areas along the Stoughton Alternative corridor. The number of impacted wetlands and the total size of the impact for each type of resource area are given for each municipality.

Direct Impacts to Wetlands in an ACEC

Several resource areas along the Stoughton alternative occur in an Area of Critical Environmental Concern (ACEC). ACECs receive special recognition because of the quality, uniqueness, and significance of natural and cultural resources. ACECs are designated by the office of the Secretary of Energy and Environmental Affairs. Massachusetts wetland regulations at 310 CMR 10.55(4)(c) state that "Any proposed work shall not destroy or otherwise impair any portion of a Bordering Vegetated Wetland that is within an Area of Critical Environmental Concern." MassDOT does not anticipate that the South Coast Rail project can be constructed in full compliance with this performance standard. A Variance will be sought for the project because there are several performance standards for BVW and other resource areas that cannot be met.

The Stoughton alternative crosses the Hockomock Swamp ACEC in Easton and Raynham. Within the Hockomock Swamp ACEC, six wetlands would be directly impacted by the project. This includes the perennial stream that has formed within the right-of-way in Raynham.

Reconstructing the existing inactive rail line in Easton and Raynham would result in permanent impact to BVW in five wetlands, with 6,561 sf (0.2 acre) of impact, and temporary impact to BVW in six wetlands, with 6,287 sf (0.1 acre) of impact, for a total of 12,848 sf (0.3 acre) of alteration to BVW. Bank would be permanently impacted in one location, for a total of 6,579 lf of impact. LUW would be permanently and temporarily impacted in one wetland, with a total of 66,334 sf (1.5 acres) of permanent impact and 401 sf (<0.1 acre) of temporary impact. BLSF would be permanently impacted in one location, for a total of 32,900 sf of impact. RA would be permanently impacted in one location, for a total of 100,449 sf (2.3 acres) of impact. The majority of the BVW impacts would occur as a result of widening the existing berm to reconstruct the inactive rail line along Wetland EA 63 (200). The entirety of the Bank, LUW, and RA impacts would result from relocating the perennial stream that has formed within the right-of-way in Raynham.

Table 4.16-33 lists the wetlands that are directly impacted in the Hockomock Swamp ACEC, along with the type and amount of each impact.

Direct Impacts by Cover Type

This section quantifies and discusses the direct impacts to vegetation cover types along the Stoughton Alternative. Totals of each cover type will be used when determining mitigation goals. Using the analysis methods previously described, direct impacts were calculated to Cowardin cover types in each municipality along the right-of-way:

- Palustrine Forested (PFO);
- Palustrine Scrub-Shrub (PSS);
- Palustrine Emergent Marsh (PEM); and
- Open Water (OW).

These cover types encompass the state resource areas of BVW, LUW, and ILSF, as well as the federal resource areas of AFW, IFW, and WW. Impacts were further calculated for PFO subtypes of Wooded Swamp Deciduous (WSD) and Wooded Swamp Mixed (WSM), and PEM subtypes of Shallow Marsh (SM) and Deep Marsh (DM). The subtypes were obtained from MassGIS data layers showing cover type; however, where direct observation showed different conditions than the data layer, the direct observation data were used. Impacts were then totaled for each municipality as a whole.

Table 4.16-34 gives a summary of the direct impacts to cover types along the Stoughton Alternative corridor. The number of impacted wetlands and the total size of the impact for each cover type are given for each municipality. Totals for the entire length of the project are also given. The direct impacts to the cover types in each municipality are presented below.

Table 4.16-34 Direct Impacts by Cover Type–Stoughton Alternative

Notes: Cowardin Types: OW = Open Water, PEM = Palustrine Emergent, PSS = Palustrine Scrub/Shrub PFO = Palustrine Forested.
PFO Subgroups: WSD = Wooded Swamp Deciduous, WSM = Wooded Swamp Mixed trees.

Reconstructing the existing active rail line in Canton would result in permanent and temporary impact to PFO in two wetlands, with a total of 1,200 square feet (sf) (<0.1 acre) of permanent impact and 1,436 sf (<0.1 acre) of temporary impact. All PFO impacts are of the subtype WSD. PSS would be temporarily impacted in one wetland, with a total of 303 sf (<0.1 acre) of impact. PEM would be temporarily impacted in one wetland, with a total of 310 sf (<0.1 acre) of impact. All PEM impacts are of the subtype SM. OW would be temporarily impacted in one wetland, with a total of 229 sf (<0.1 acre) of impact.

Reconstructing the existing active and inactive rail line in Stoughton would result in permanent impact to PFO in six wetlands, with a total of 86,184 sf (2.0 acres) of impact, and temporary impact to PFO in four wetlands, with a total of 5,417 sf (0.1 acre) of impact. All PFO impacts are of the subtype WSD. PSS would not be impacted. PEM would be permanently and temporarily impacted in two wetlands, with a total of 1,545 sf (<0.1 acre) of permanent impact and 1,087 sf (<0.1 acre) of temporary impact. All PEM impacts are of the subtype SM. OW would not be impacted.

Reconstructing the existing inactive rail line in Easton would result in permanent impact to PFO in six wetlands, with a total of 2,784 sf (0.1 acre) of impact, and temporary impact to PFO in nine wetlands, with a total of 5,388 sf (0.1 acre) of impact. All PFO impacts are of the subtype WSD. PSS would be permanently and temporarily impacted in three wetlands, with a total of 14,198 sf (0.3 acre) of permanent impact and 2,081 (<0.1 acre) of temporary impact. PEM would be permanently impacted in two wetlands, with a total of 1,151 sf (<0.1 acre) of impact, and temporarily impacted in three wetlands, with a total of 1,796 sf (<0.1 acre) of impact. All PEM impacts are of the subtype DM. OW would not be impacted. No direct impacts would occur to any Atlantic white cedar areas in the Hockomock Swamp because the tracks would be on an elevated trestle through the swamp.

Reconstructing the existing inactive rail line in Raynham would result in permanent impact to PFO in 12 wetlands, with a total of 56,685 sf (1.3 acres) of impact, and temporary impact to BVW in 14 wetlands, with a total of 35,322 sf (0.8 acre) of impact. PFO impacts are nearly all of the subtype WSD, except for 412 sf (<0.1 acre) of permanent and 766 sf (<0.1 acre) of temporary WSM impact. PSS would be permanently impacted in three wetlands, with a total of 1,367 sf (<0.1 acre), and temporarily impacted in four wetlands, with a total of 4,590 sf (0.1 acre) of impact. PEM would not be impacted. OW would be permanently impacted in two wetlands, with a total of 66,528 sf (1.5 acres) of impact, and temporarily impacted in four wetlands, with a total of 3,639 sf (0.1 acre) of impact. No areas of Atlantic white cedar present in the Hockomock Swamp or the Pine Swamp would be impacted.

Reconstructing the existing active and inactive rail line in Taunton would result in permanent impact to PFO in 20 wetlands, with a total of 58,326 sf (1.3 acres) of impact, and temporary impact to BVW in 23 wetlands, with a total of 51,443 sf (1.2 acres) of impact. All PFO impacts are of the subtype WSD. PSS would not be impacted. PEM would be permanently and temporarily impacted in four wetlands, with a total of 25,359 sf (0.6 acre) of permanent impact and 7,346 sf (0.2 acre) of temporary impact. All PEM impacts are of the subtype SM. OW would be temporarily impacted in one wetland, with a total of 1,067 sf (<0.1 acre) of impact.

Reconstructing the existing active rail lines in Berkley would result in permanent impact to PFO in 11 wetlands, with a total of 48,825 sf (1.1 acres) of impact, and temporary impact to PFO in 15 wetlands, with a total of 35,366 sf (0.8 acre) of impact. PFO impacts are nearly all of the subtype WSD, except for 5,963 sf (0.1 acre) of permanent and 1,721 sf (<0.1 acre) of temporary WSM impact. PSS would be permanently and temporarily impacted in two wetlands, with a total of 10,214 sf (0.2 acre) of permanent impact and 4,608 sf (0.1 acre) of temporary impact. PEM and OW would not be impacted.

Reconstructing the existing active rail lines in Lakeville would result in permanent impact to PFO in nine wetlands, with a total of 31,592 sf (0.7 acre) of impact, and temporary impact to PFO in nine wetlands, with a total of 23,106 sf (0.5 acre) of impact. All PFO impacts are of the subtype WSD. PSS would be permanently impacted in two wetlands, with a total of 2,971 sf (0.1 acre) of impact, and temporarily impacted in one wetland, with a total of 514 sf (<0.1 acre) of impact. PEM would not be impacted. OW would be temporarily impacted in one wetland, with a total of 829 sf (<0.1 acre) of impact. No areas of Atlantic white cedar, present in the Assonet Cedar Swamp, would be impacted.

Reconstructing the existing active rail lines in Freetown would result in permanent impact to PFO in 12 wetlands, with a total of 35,248 sf (0.9 acre) of impact, and temporary impact to PFO in 21 wetlands, with a total of 17,683 sf (0.4 acre) of impact. All PFO impacts are of the subtype WSD. PSS would be permanently impacted in five wetlands, with a total of 8,395 sf (0.2 acre) of impact, and temporarily impacted in seven wetlands, with a total of 2,071 sf (<0.1 acre) of impact. PEM would be permanently and temporarily impacted in two wetlands, with a total of 1,667 sf (<0.1 acre) of permanent impact and 4,848 sf (0.1 acre) of temporary impact. All PEM impacts are of the subtype SM. OW would be permanently and temporarily impacted in two wetlands, with a total of 14,072 sf (0.3 acre) of permanent impact and 6,379 sf (0.1 acre) of temporary impact.

Reconstructing the existing active rail line in New Bedford would result in permanent impact to PFO in 10 wetlands, with a total of 34,504 sf (0.8 acre) of impact, and temporary impact to PFO in 10 wetlands, with a total of 26,303 sf (0.6 acre) of impact. PFO impacts are nearly all of the subtype WSD, except for 1,043 sf (<0.1 acre) of permanent and 3,160 sf (0.1 acre) of temporary WSM impact. PSS would be permanently and temporarily impacted in one wetland, with a total of 879 sf (<0.1 acre) of permanent impact and 2,766 sf (0.1 acre) of temporary impact. PEM would be permanently and temporarily impacted in one wetland, with a total of 16,176 sf (0.4 acre) of permanent impact and 1,140 sf (<0.1 acre) of temporary impact. PEM impacts are all of the subtype SM. No areas of Atlantic white cedar, present in the Acushnet Cedar Swamp, would be impacted.

Reconstructing the existing active rail line in Fall River would result in permanent impact to PFO in two wetlands, with a total of 1,647 sf (<0.1 acre) of impact, and temporary impact to PFO in three wetlands, with a total of 2,192 sf (0.1 acre) of impact. PFO impacts are all of the subtype WSD. PSS and PEM would not be impacted.

In summary, reconstructing the existing active and inactive rail lines along the Stoughton alternative would result in permanent impact to PFO in 93 wetlands, with 8.5 acres of impact, and temporary impact to PFO in 115 wetlands, with 4.8 acres of impact, for a total of 13.3 acres of alteration to PFO (Table 4.16-34).

PSS would be permanently impacted in 16 wetlands, with a total of 0.9 acres of impact, and temporarily impacted in 19 wetlands, with a total of 0.4 acres of impact. The largest PSS impacts are associated with Wetland EA 12.1 in Easton, a narrow wetland area that has formed within the right-of-way.

PEM would be permanently impacted in 12 wetlands, with a total of 1.0 acre of impact, and temporarily impacted in 14 wetlands, with a total of 0.4 acres of impact. The largest PEM impacts are associated with Wetland T 42 (200) in Taunton, an emergent wetland that has formed within the right-of-way.

OW would be permanently impacted in four wetlands, with a total of 1.9 acres of impact, and temporarily impacted in nine wetlands, with a total 0.3 acres of impact. The largest OW impacts would occur in Wetland R 62.1 in Raynham, in order to relocate a perennial stream that has formed in the

right-of-way due to blocked drainage ditches, and in Wetlands FRF 11 and FRF 12 in Freetown, where Terry Brook Pond occurs on both sides of the right-of-way.

Direct Impacts to Jurisdictional Wetlands/Waters by Watershed

The Stoughton Alternative crosses the Neponset, Taunton, Buzzards Bay, and Narragansett Bay regional watersheds. Direct impacts to jurisdictional wetlands/waters that fall within each watershed were calculated to help guide the development of mitigation measures. The majority of the project corridor falls within the Taunton regional watershed. Of the approximately 52.1 miles of the total rail length of the project, approximately 39.9 miles lie in the Taunton watershed, 4.7 miles in the Neponset watershed, 6.8 miles in the Buzzards Bay watershed, and 0.7 mile in the Narragansett Bay watershed. The majority of direct impacts also occur in the Taunton watershed. A total of 102 of the 123 wetlands that would be permanently impacted are in the Taunton watershed, with 9.1 of the 10.7 acres of total permanent impact. A total of 128 of the 151 wetlands that would be temporarily impacted are also in the Taunton watershed, with 4.7 of the 5.6 acres of total temporary impact. In the Neponset watershed, three wetlands would be permanently and temporarily impacted, with a total of less than 0.1 acre of permanent impact and less than 0.1 acre of temporary impact. In the Buzzards Bay watershed, 15 wetlands would be permanently impacted, with a total of 1.3 acres of impact, and 16 wetlands would be temporarily impacted, with a total of 0.8 acre of impact. In the Narragansett Bay watershed, three wetlands would be permanently and temporarily impacted, with 0.2 acre of permanent impact and less than 0.1 acre of temporary impact. Impacts to Outstanding Resource Waters (ORWs) include those wetlands associated with vernal pools. A detailed discussion of vernal pool impacts is provided in Chapter 4.14, *Biodiversity, Wildlife and Vegetation*. Table 4.16-35 lists the watersheds in the South Coast Rail project corridor, the number of wetlands impacted in each, and the amount of each impact.

Table 4.16-35 Direct Impacts to Vegetated Wetlands by Watershed

Watershed	Waterbody/Waterway		Adjacent Federal Wetlands		Isolated Federal Wetlands		ORW Impacts	
	Perm. (#/ac)	Temp. (#/ac)	Perm. (#/ac)	Temp. (#/ac)	Perm. (#/ac)	Temp. (#/ac)	Perm. (#/ac)	Temp. (#/ac)
Neponset	-	1/<0.1	2/<0.1	4/<0.1	-	-	-	-
Taunton	4/1.9	8/0.3	91/8.3	113/4.6	13/0.8	14/0.1	26/1.5	32/1.5

TOTAL	**4/1.9**	**9/0.3**	**106/9.6**	**132/5.4**	**15/0.8**	**16/0.1**	**26/1.5**	**32/1.5**

Stoughton Diesel

Impacts to wetlands for the Stoughton Diesel Alternative are similar to the impacts identified above for the Stoughton Electric Alternative. The diesel alternative does not require traction power substations and would result in approximately 0.01 acre of permanent wetland impacts less than the Stoughton Electric Alternative along the New Bedford Main Line. All other impacts are the same as those estimated for the remainder of Stoughton Electric Alternative.

Whittenton Electric Alterative

The Whittenton Electric Alternative is a variant of the Stoughton Electric Alternative alignment described in the section on the Stoughton Electric Alternative. Specifically, at Raynham Junction near the southern end of the historic Stoughton Line, the alignment would divert to the southwest, following the old Whittenton Branch (Figures 4.16-4a-j). This alignment would connect with the Attleboro Secondary at Whittenton Junction in Taunton, and then continue southeast to connect with the New Bedford Main Line at Weir Junction, at the northern end of the Southern Triangle. Service along the southernmost portion of the Stoughton Line, from Raynham Junction to Weir Junction, would not be reestablished if this variant were selected. The Southern Triangle portion of the project is common to all alternatives and requires the rail bed, track, and signals along the existing Fall River Secondary and New Bedford Main Lines to be upgraded for passenger rail traffic. This portion of the project extends from Cotley Junction in Taunton along the New Bedford Main Line through Berkley, Lakeville, Freetown, and New Bedford and along the Fall River Secondary from Myricks Junction in Lakeville through Freetown and Fall River (Figures 4.16-2a-q and 4.16-3a-j).

This alternative would include Battleship Cove Station, Canton Center Station, Canton Junction Station, Dana Street Station, Easton Village Station, Fall River Depot Station, Freetown Station, King's Highway Station, North Easton Station, Raynham Park Station, South Station, Stoughton Station, Taunton Depot Station, and Whale's Tooth Station. The alternative includes two layover facilities (Weaver's Cove East on the Fall River Secondary and Wamsutta on the New Bedford Main Line. Potential impacts to wetland resources resulting from developing the new stations and layover facilities are inclusive and not discussed separately.

No construction would be required along the Northeast Corridor and the existing Stoughton Line commuter rail track from Canton Junction to Stoughton would be upgraded for the Whittenton Electric Alternative. New track would be installed on the existing embankment from Stoughton south to Raynham Junction. Similar to the Stoughton alternative a section from Foundry Street in Easton to Raynham Station through the Hockomock Swamp would be constructed on an elevated trestle (Figures 4.16-2k and l). Canopy clearing would be required along the right-of-way where the elevated trestle would be located within the Hockomock Swamp to accommodate additional height requirements associated with the trestle. Canopy clearing generally occurs within upland forest, though portions would occur in wetland resources. Canopy clearing would not result in additional impacts to wetland resources as this work would occur in uplands.

The alignment of the proposed Whittenton Alternative follows a previously developed railroad corridor. Although the rail corridor has been established, necessary track improvements would result in the loss of wetland resources along the right-of-way. The following sections describe both direct and indirect impacts as they relate to this alternative.

Direct Impact to State and Federal Resource Areas by Municipality

With the exception of those impacts within Raynham and Taunton, the direct impacts to state resources for the Whittenton Alternative are the same as those reported previously for the Stoughton alternative.

For the towns of Canton, Stoughton, Easton, Berkley, Lakeville, and Freetown, and the cities of New Bedford and Fall River, the impacts to State and Federal Resources are as reported for the Stoughton Electric Alternative, in Tables 4.16-32, above.

This section also quantifies and discusses the federal waters of the United States (including wetlands) affected by the Whittenton Alternative. These waters are assumed jurisdictional under Section 404 of the Clean Water Act. They are also regulated at the state level by 314 CMR 9.00, which implements the Federal Clean Water Act Section 401 Water Quality Certification program for a discharge of dredged or fill material.

Using the analysis methods described previously, direct impacts (both permanent and temporary) were calculated to federal wetlands in each municipality. Impacts were totaled for each municipality as a whole. The direct impacts to federal wetlands in each municipality are presented below. As previously described, some small isolated wetlands within the project corridor are assumed to be jurisdictional under Section 404.

Raynham—The Raynham segment of the Whittenton alternative includes approximately 2.8 miles along an inactive portion of the Stoughton Line and approximately 1.2 miles along an inactive portion of the Whittenton Branch. Reconstructing the existing inactive rail line in Raynham would result in permanent impact to BVW in 9 wetlands, with 24,172 sf (0.5 acre) of impact, and temporary impact to BVW in 12 wetlands, with 18,081 sf (0.4 acre) of impact for a total of 42,253 sf (1.0 acre) of alteration to BVW. Bank would be permanently impacted in five locations, with a total of 6,773 lf of impact. LUW would be permanently impacted in one wetland with a total of 66,334 sf (1.5 acres) of impact, and temporarily impacted in the same wetland, with a total of 401 sf (<0.1 acre) of impact. BLSF would be permanently impacted in two locations, with a total of 50,814 sf (1.2 acres) of impact. RA would be permanently impacted in one location, with a total of 100,449 sf (2.3 acres) of new development. The Whittenton Alternative avoids impacts in the Pine Swamp area.

The Whittenton Alternative would result in permanent impact to nine VWs, with a total of 24,172 sf (0.6 acre) of impact, and temporary impact to 12 VWs, with a total of 18,081 sf (0.4 acre) of impact. One WW area would be impacted, with a permanent impact of 66,334 sf (1.5 acres) and a temporary impact of 401 sf (<0.1 acre). Table 4.16-36 lists the impacted wetlands in Raynham and the size of each impacted area.

Table 4.16-36 Direct Impacts to State and Federal Resource Areas–Raynham

Notes: Wetland Classifications: BVW = Bordering Vegetated Wetland, LUW=Land Under Water, BLSF = Bordering Land Subject to Flooding, ILSF = Isolated Land Subject to Flooding, RA = Riverfront Area.

Taunton—In Taunton, the Whittenton alternative includes approximately 2.2 miles along an inactive portion of the of the Whittenton Branch, a 2.4 mile segment of the active Attleboro Secondary, as well as, a portion of the New Bedford Main Line from Weir Junction to Cotley Junction. Reconstructing the existing active and inactive rail lines in Taunton would result in permanent impact to BVW in 15 wetlands, with 53,145 sf (1.2 acres) of impact, and temporary impact to BVW in 17 wetlands, with 46,040 sf (1.1 acres) of impact, for a total of 99,185 sf (2.3 acres) of alteration to BVW. Bank would be permanently impacted in two locations, with a total of 457 lf of impact. LUW would not be impacted. BLSF would be permanently impacted in three locations, with a total of 32,706 sf (0.8 acre) of impact. RA would be permanently impacted in five locations, with a total of 61,390 sf (1.4 acres) of new development.

Taunton has some of the largest direct wetland impacts along the project corridor. Several wetlands have formed partially or mostly within the inactive right-of-way and would be impacted. Additional direct wetland impacts in Taunton would include 0.7 acre of RA and 0.5 acre of BLSF associated with the Taunton River (Wetlands TCM 1.2 and TR (Crossing 2)).

Reconstructing the existing active and inactive rail line in Taunton would result in permanent impact to 17 VWs, with a total of 71,326 sf (1.6 acres) of impact, and temporary impact to 19 VWs, with a total of 50,015 sf (1.1 acres) of impact. Taunton would have some of the largest direct wetland impacts along the project corridor. Several wetlands have formed partially or mostly within the inactive right-of-way and would be impacted. Table 4.16-37 lists the impacted wetlands in Taunton and the size of each impacted area.

Notes: Wetland Classifications: BVW = Bordering Vegetated Wetland, LUW=Land Under Water, BLSF = Bordering Land Subject to Flooding, ILSF = Isolated Land Subject to Flooding, RA = Riverfront Area.

Summary of Direct Impacts to State and Federal Resource Areas—Reconstructing the existing active and inactive rail lines along the Whittenton alternative would result in permanent impact to BVW in 92 wetlands, with 8.4 acres of impact, and temporary impact to BVW in 117 wetlands, with 4.7 acres of impact, for a total of 13.1 acres of alteration to BVW. BVW impacts would result from reconstructing and widening existing berms associated with the rail lines, and filling wetlands that have formed within the right-of-way. The majority of impacts are to one wetland, Wetland TWB 08.1, just south of Bay Street in the Taunton section of the Whittenton Branch. While a large portion of this wetland would be filled in order to construct the railroad, this is a disturbed, mainly unvegetated wetland that has developed within the right-of-way due to compression of soils from ATV and other use of the path. The area is isolated and does not provide wetland functions and values other than a minor amount of groundwater recharge through infiltration into sections of former drainage ditches along either side of the right-of-way.

Bank would be permanently impacted in 41 locations, with a total of 16,581 lf of impact. The largest Bank impacts would occur in:

- Raynham (6,773 lf of impact);
- Easton (5,423 lf of impact); and
- Freetown (2,460 lf of impact).

LUW would be permanently impacted in three wetlands, with a total of 1.8 acres of impact, and temporarily impacted in five wetlands, with a total of 0.2 acre of impact. LUW impacts would largely result mainly from relocating the perennial stream in Raynham and filling Terry Brook Pond in Freetown.

BLSF would be permanently impacted in 28 locations, with a total of 5.0 acres of impact. The largest BLSF impacts would occur in Raynham as a result of relocating the perennial stream.

RA would be permanently impacted in 21 locations, with a total of 7.8 acres of new development of naturally vegetated land outside of the existing ballast and other active rail elements. The largest RA impacts would occur in Raynham as a result of relocating the perennial stream.

Coastal Bank would be permanently impacted in four locations in Fall River, with a total of 274 lf of impact.

LSCSF would be permanently impacted in three locations in Fall River, with a total of 0.6 acres of impact, associated with the Taunton River.

Reconstructing the existing active and inactive rail lines along the project corridor would result in permanent impact to 106 VWs, with 9.4 acres of impact, and temporary impact to 131 VWs, with 4.9 acres of impact, for a total of 14.3 acres of alteration to VWs. Impacts to VWs would result from reconstructing and widening existing berms associated with the rail lines, and would impact wetlands that have formed within the right-of-way.

Three WW areas would be permanently impacted, with a total of 1.8 acres of impact, and five WW areas would be temporarily impacted, with a total of 0.2 acre of impact. WW impacts would result mainly from relocating a perennial stream that has formed within the right-of-way in Raynham due to blocked

drainage culverts, and filling portions of Terry Brook Pond in Freetown on both sides of the right-of-way in order to widen the existing berm.

Table 4.16-38 summarizes the direct impacts to state and federal wetland resource areas along the Whittenton Alternative corridor. The number of impacted wetlands and the total size of the impact for each type of resource area are given for each municipality.

Direct Impacts to Wetlands in an ACEC

Similar to the Stoughton alternative, the Whittenton alternative crosses the Hockomock Swamp ACEC in Easton and Raynham. Within the Hockomock Swamp ACEC, six wetlands would be directly impacted by the project. This includes the perennial stream that has formed within the right-of-way in Raynham. Table 4.16-33 lists the wetlands that are directly impacted in the Hockomock Swamp ACEC, along with the type and amount of each impact.

Direct Impacts by Cover Type

This section quantifies and discusses the direct impacts to vegetation cover types along the Whittenton Alternative. Totals of each cover type will be used when determining mitigation goals. Direct impacts were calculated to Cowardin cover types in each municipality along the right-of-way. Using the analysis methods previously described.

Table 4.16-39 gives a summary of the direct impacts to cover types along the Whittenton corridor. The number of impacted wetlands and the total size of the impact for each cover type are given for each municipality. Totals for the entire length of the project are also given. The direct impacts to the cover types in each municipality are presented below.

Table 4.16-38 Direct Impacts to State and Federal Resource Areas along the Whittenton Alternative

Notes: Cowardin Types: OW = Open Water, PEM = Palustrine Emergent, PSS = Palustrine Scrub/Shrub PFO = Palustrine Forested.
PFO Subgroups: WSD = Wooded Swamp Deciduous, WSM = Wooded Swamp Mixed trees.

In comparison to the impacts previously discussed for the Stoughton Alternative, all impacts are the same with the exceptive of two municipalities, Raynham and Taunton. Reconstructing the existing inactive rail lines in Raynham would result in permanent impact to PFO in six wetlands, with a total of 0.5 acre of impact, and temporary impact to BVW in eight wetlands, with a total of 0.4 acre of impact. PFO impacts are all of the subtype WSD. PSS would be permanently impacted in three wetlands, with a total of <0.1 acre, and temporarily impacted in three wetlands, with a total of 0.1 acre of impact. PEM would not be permanently impacted. OW would be permanently impacted in one wetland, with 1.5 acres of impact, and temporarily impacted in one wetland, with <0.1 acre of impact. No areas of Atlantic white cedar present in the Hockomock Swamp would be impacted.

Reconstructing the existing active and inactive rail lines in Taunton would result in permanent impact to PFO in 16 wetlands, with a total of 1.5 acres of impact, and temporary impact to BVW in eight wetlands, with a total of 0.4 acre of impact. All PFO impacts are of the subtype WSD. The majority of impacts are to one wetland, Wetland TWB 08.1, just south of Bay Street in the Taunton section of the Whittenton Branch. This wetland has developed within the right-of-way and a large portion would be filled in order to construct the railroad. Although this wetland has been classified as palustrine forested area, this is a disturbed, mainly unvegetated wetland that has developed within the right-of-way due to compression of soils from ATV and other use of the path. The area is isolated and does not provide wetland functions and values other than a minor amount of groundwater recharge through infiltration into sections of former drainage ditches along either side of the right-of-way. PSS would not be impacted. PEM would be permanently impacted in one wetland with a total of 0.1 acre of impact and temporarily impacted in one wetland with 0.1 acre of temporary impact. All PEM impacts are of the subtype SM. OW would not be impacted.

In summary, reconstructing the existing active and inactive rail lines along the Whittenton alternative would result in permanent impact to PFO in 82 wetlands, with 7.9 acres of impact, and temporary impact to PFO in 102 wetlands, with 4.2 acres of impact, for a total of 12.1 acres of alteration to PFO (Table 4.16-39).

PSS would be permanently impacted in 16 wetlands, with a total of 0.9 acre of impact, and temporarily impacted in 18 wetlands, with a total of 0.3 acre of impact. The largest PSS impacts are associated with Wetland EA 12.1 in Easton, a narrow wetland area that has formed within the right-of-way.

PEM would be permanently impacted in 8 wetlands, with a total of 0.6 acre of impact, and temporarily impacted in 11 wetlands, with a total of 0.3 acre of impact. The largest PEM impacts are associated with Wetland T 42 (200) in Taunton, an emergent wetland that has formed within the right-of-way

OW would be permanently impacted in three wetlands, with a total of 1.8 acres of impact, and temporarily impacted in five wetlands, with a total 0.2 acres of impact. The largest OW impacts would occur in Wetland R 62.1 in Raynham, in order to relocate a perennial stream that has formed in the right-of-way due to blocked drainage ditches, and in Wetlands FRF 11 and FRF 12 in Freetown, where Terry Brook Pond occurs on both sides of the right-of-way.

Direct Impacts to Wetlands/Waters by Watershed

The Whittenton Alternative crosses the Neponset, Taunton, Buzzards Bay, and Narragansett Bay regional watersheds. Direct impacts to vegetated wetlands that fall within each watershed were calculated to help guide the development of mitigation measures. The majority of the project corridor falls within the Taunton regional watershed. Of the approximately 52.1 miles of the total rail length of

the project, approximately 39.9 miles lie in the Taunton watershed, 4.7 miles in the Neponset watershed, 6.8 miles in the Buzzards Bay watershed, and 0.7 mile in the Narragansett Bay watershed. The majority of direct impacts also occur in the Taunton watershed. A total of 87 of the 106 wetlands that would be permanently impacted are in the Taunton watershed, with 8.1 of the 9.4 acres of total permanent impact. A total of 108 of the 133 wetlands that would be temporarily impacted are also in the Taunton watershed, with 4.0 of the 4.8 acres of total temporary impact. In the Neponset watershed, three wetlands would be permanently and temporarily impacted, with a total of less than 0.1 acre of permanent impact and less than 0.1 acre of temporary impact. In the Buzzards Bay watershed, 15 wetlands would be permanently impacted, with a total of 1.3 acres of impact, and 16 wetlands would be temporarily impacted, with a total of 0.8 acre of impact. In the Narragansett Bay watershed, two wetlands would be permanently impacted with less than 0.1 acre of impact and three wetlands would be temporarily impacted, with 0.1 acre of impact. Impacts to Outstanding Resource Waters (ORWs) include those wetlands associated with vernal pools. A detailed discussion of vernal pool impacts is provided in Chapter 4.14, *Biodiversity, Wildlife and Vegetation*. Table 4.16-40 lists the watersheds in the South Coast Rail project corridor, the number of wetlands impacted in each, and the amount of each impact.

Table 4.16-40 Direct Impacts to Wetlands/Waters by Watershed

	Waterbody/Waterway		Vegetated Wetlands		ORW Impacts	
Watershed	Perm. (#/ac)	Temp. (#/ac)	Perm. (#/ac)	Temp. (#/ac)	Perm. (#/ac)	Temp. (#/ac)
Neponset	-	1/<0.1	2/<0.1	4/<0.1	-	-
Taunton	3/1.8	4/0.2	87/8.1	108/4.0	17 /1.1	21/1.3
Buzzards Bay	-	-	15/1.3	16/0.8	-	-
Narragansett Bay	-	-	2/<0.1	3/0.1	-	-
TOTAL	3/1.8	5/0.2	106/9.4	131/4.9	17/1.1	21/1.3

Whittenton Diesel Alternative

Impacts to wetlands for the Whittenton Diesel Alternative are similar to the impacts identified above for the Whittenton Electric Alternative. The diesel alternative does not require traction power substations and would result in approximately 0.01 acre of permanent wetland impacts less than the Whittenton Electric Alternative along the New Bedford Main Line. All other impacts are the same as those estimated for the remainder of Whittenton Electric Alternative.

4.16.9.3 Secondary and/or Indirect Impact Analysis

As described in Section 4.16.6.2 the Secondary and/or Indirect Impact Analysis evaluated the effects of the alternatives on wetland functions and values for all wetlands within 100 feet of the project limits for the Stoughton and Whittenton alternatives. These impacts cannot be quantified, but are presented in a qualitative approach that identifies, for each wetland, the principal functions and values provided by that wetland, the magnitude of impact to those functions based on the physical extent of the impacts in comparison to the overall size of the wetland.

Secondary and/or indirect effects are changes in the ability of a wetland to provide each function, and do not affect a wetland uniformly (except for some small wetlands). These functional effects occur as gradients with the highest intensity occurring closest to the disturbance and decreasing with distance.

Each resource affected may also experience the effects differently – for example, the effects of a canopy gap do not affect all wildlife species in the same way, or at the same distance. While some researchers have considered a secondary effect ("road effect") to alter the entire wetland, others have documented that the effects of highways are not uniformly distributed across a wetland. Effects on the ability of a wetland to support production export are different in type and location than on the ability of a wetland to provide sediment/toxicant retention or nutrient transformation. Eigenbrod et al.[33] have shown that the ability of a wetland to provide wildlife habitat functions is multivariate, and includes size, edge: interior ratio, cover type, connectivity, microhabitat diversity, soil moisture, and other factors. Their work has shown that the most important variable is wetland size, and that changes in wetland size in small wetlands has a much greater effect on wildlife species richness than changes in size in larger wetlands.

For these reasons, the analysis of secondary and/or indirect effects has estimated the severity of the effect of the South Coast Rail project (reconstructing out-of-service rail infrastructure, reconstructing active rail infrastructure, adding infrastructure necessary for electric service, and constructing stations) on each adjacent or nearby wetland by ranking the impact based on the relative extent of impact in comparison to the overall size of the wetland, for each key function or value provided by that wetland.

Wetlands within 100 feet of the South Coast Rail project could experience secondary and/or temporary impacts to wetland functions as a result of the permanent loss of a portion of the wetland, temporary impacts resulting from construction, and/or proximity to the project. These impacts would differ, for some resources, depending on whether the adjacent project area is an active rail corridor or out-of-service.

Active Rail Segments

Active rail segments are characterized by a developed (ballasted) rail bed and tracks, which create a canopy gap and barrier to wildlife movement. Work proposed along these segments would improve wildlife passage by reconstructing bridges and culverts, and installing between-the-tie crossings to accommodate smaller fauna such as amphibians, but would not change the characteristics of the upland. The only effects of the proposed project would be to increase train passage and a minor increase in noise levels due to the increased number of trains.

The physical characteristics of those wetlands within 100 feet of the project limit-of-work not directly affected by construction would not change. The increased train passage is not anticipated to adversely affect the wildlife habitat function of adjacent or nearby wetlands (see Chapter 4.14, *Biodiversity, Wildlife, and Vegetation*).

The introduction of the overhead catenary system required for the Electric Alternatives could affect the visual quality of wetlands, where there are views of the wetland from a public way or across a navigable waterway. There could be a negligible effect on the ability of waterways to provide fish habitat as a result of tree clearing within 25 feet of the bank.

Secondary and/or indirect effects to physical and biochemical functions (groundwater recharge, sediment/toxicant retention, flood storage, nutrient retention/transformation, production export) are

[33] Eigenbrod, F., S.J. Hecnor, and L. Fahrig. 2009. Quantifying the road-effect zone: threshold effects of a motorway on anuran populations in Ontario, Canada. Ecology and Society 14:24. Available online at: http://www.ecologyandsociety.org/vol14/iss1/art24.

related to the loss of the wetland that provides these functions, and impacts would be proportionate to the size of the lost area relative to the total wetland size. Areas of temporary construction impact would be restored to the same elevation and re-vegetated, with no loss of wetland function for these physical and biochemical functions. In general, reductions in sediment/toxicant/pathogen removal and nutrient removal/transformation would result from a reduced opportunity for sediment trapping, reduced vegetation/water interspersion, and changes in the type and density of vegetation. The ability of a wetland to provide production export would be affected by reduction in wildlife food sources, reduced wildlife usage, and a potentially reduced diversity of wetland plants.

Secondary effects to wildlife habitat functions would result from a loss of wetland that provides wildlife habitat function, or from canopy removal in forested wetlands as the canopy edge effects would extend further into the wetland. The loss of a portion of a wetland would reduce the effective habitat size for all species, and more so for forest interior species. These effects would be exacerbated by the barrier and noise effects. Barrier effects (and creation of a canopy gap that reduces the size of forest interior habitat) would result in the reduction of effective contiguous habitat size for populations of some species (especially reptiles, amphibians, some small mammals, some forest interior birds) as documented in Chapter 4.14, *Biodiversity, Wildlife, and Vegetation*.

Areas of temporary impact would be restored, but create the potential for establishment of invasive species such as common reed or reed canary-grass (*Phalaris arundinacea*) that reduce wetland habitat quality in the impacted area and can spread throughout the wetland. Where the wetland is a vernal pool, or contains vernal pool habitat, the same effects occur and further reduce the wildlife habitat functions through the reduction of effective habitat size. The loss of vegetation on the rail berm within vernal pool supporting upland habitat could affect the population size of vernal pool amphibians. Reconstructing the rail infrastructure in some upland areas could affect the habitat of state-listed rare species (turtles, blue-spotted salamanders) in some wetlands.

Impacts to fisheries habitat would occur only where fill would be placed in pond or other waterway/waterbody with fisheries value, or where removing vegetation from or near a riverbank could affect shading. Impacts to recreational functions would occur where fill would be placed in pond or other waterway/waterbody accessible to/used for fishing.

Out-of-Service Rail Segments

Out-of-service rail segments are characterized by a developed (ballasted) rail bed, but also have a closed canopy in some areas and no tracks or ties remaining in place between Short Street in Easton and Longmeadow Road in Taunton. Work proposed along these segments would improve wildlife passage by reconstructing bridges and culverts, but would result in a barrier to the movement of some terrestrial wildlife species, and would increase the canopy gap in forested areas.

The physical characteristics of those wetlands within 100 feet of the project limit-of-work not directly affected by construction would not change. As a result no secondary or indirect effects to wetland functions or values would be anticipated (groundwater recharge, sediment/toxicant retention, flood storage, nutrient removal/transformation, production export, uniqueness/heritage).

The increased train passage is not anticipated to adversely affect the wildlife habitat function of adjacent or nearby wetlands (see Chapter 4.14, *Biodiversity, Wildlife, and Vegetation*). The introduction of the overhead catenary system could affect the visual quality of wetlands, where there are views of the wetland from a public way or across a navigable waterway.

Secondary effects to wetland wildlife habitat, where this is a principal function, would occur as a result of the barrier and noise effects. Barrier effects (and creation of a canopy gap that reduces the size of forest interior habitat) would result in the reduction of effective contiguous habitat size for populations of some species (especially reptiles, amphibians, some small mammals, some forest interior birds) as documented in Chapter 4.14, *Biodiversity, Wildlife, and Vegetation*. In Hockomock Swamp, the proposed trestle structure would largely eliminate the barrier effect. The loss of vegetation on the rail berm within vernal pool supporting upland habitat could affect the population size of vernal pool amphibians. However, it should be noted that re-establishment of commuter rail service would eliminate use of the right-of-way by ATV users that currently and regularly leave the right-of-way to enter, cross through, and/or ride in circuitous or serpentine pathways through the vernal pools, adversely affecting amphibians in those pools, particularly at breeding, egg and larval life stages. Preventing these occurrences would presumably enhance vernal pool habitat, thereby increasing populations of vernal pool amphibians–including some that are state-listed. Thus re-establishment of commuter rail service could actually have a secondary *benefit* to vernal pool wetlands, particularly in Hockomock Swamp. However, reconstructing the rail infrastructure in some upland areas could affect the habitat of state-listed rare species (turtles, blue-spotted salamanders) in some wetlands that provide the rare species habitat function.

Other secondary effects to wetlands that are in proximity to the project alternatives include the educational use of wetlands. Reconstructing the rail bed south of Foundry Street in Easton may affect the visual quality and access to wetlands that are used by faculty and students from the Southeast Regional Vocational and Technical School to supplement in-class learning. In locations where the out-of-service right-of-way is used as a trail and/or crossed by trails, reconstructing the track infrastructure would prevent hikers or ATV users from using the right-of-way or crossing the right-of-way to access recreational areas. The proximity to the overhead catenary could also affect the visual quality of some recreational areas adjacent to the right-of-way. All of these wetlands are adjacent to the Vocational and Technical school or residences and are not open for hunting. It should be noted, however that there are no mapped designated or sanctioned trails in Stoughton, Easton, or Raynham on or across the right-of-way that would be affected, notwithstanding *de facto* usage of the right-of-way for these purposes.

Many wetlands adjacent to the right-of-way provide habitat for state-listed reptile or amphibian species. Although the actual wetland habitat would not be directly affected, construction could have a secondary effect on the endangered species functions of these wetlands by creating a barrier to the movement of small vertebrates, although in Hockomock Swamp, the proposed trestle structure would largely eliminate the barrier effect. Similar to active sections of the rail, secondary and/or indirect effects to physical and biochemical functions (groundwater recharge, sediment/toxicant retention, flood storage, nutrient retention/transformation, production export) are related to the loss of the wetland that provides these functions, and impacts would be proportionate to the size of the lost area relative to the total wetland size. Areas of temporary construction impact would be restored to the same elevation and re-vegetated, with no loss of wetland function for these physical and biochemical functions.

Secondary effects to wildlife habitat functions would result from a loss of wetland that provides wildlife habitat function, or from canopy removal in forested wetlands as the canopy edge effects would extend further into the wetland. The loss of a portion of a wetland would reduce the effective habitat size for all species, and more so for forest interior species. These effects would be exacerbated by the barrier and noise effects. Barrier effects (and creation of a canopy gap that reduces the size of forest interior habitat) would result in the reduction of effective contiguous habitat size for populations of some

species (especially reptiles, amphibians, some small mammals, and some forest interior birds) as documented in Chapter 4.14, *Biodiversity, Wildlife and Vegetation*.

Areas of temporary impact would be restored but create the potential for establishment of invasive species such as common reed or reed-canary grass that reduce wetland habitat quality in the impacted area and can spread throughout the wetland. Where the wetland is a vernal pool, or contains vernal pool habitat, the same effects occur and further reduce the wildlife habitat functions through the reduction of effective habitat size. The loss of vegetation on the rail berm within vernal pool supporting upland habitat could affect the population size of vernal pool amphibians. Reconstructing the rail infrastructure in some upland areas could affect the habitat of state-listed rare species (Blanding's turtle (*Emydoidea blandingii*) and blue spotted salamander (*Ambystoma laterale*) eastern box turtle (*Terrapene carolina carolina*)) in some wetlands that provide the rare species habitat function. Impacts to fisheries habitat would occur only where fill would be placed in pond or other waterway/waterbody with fisheries value.

Temporary wetland impacts would have similar secondary and/or indirect effects on wetlands adjacent to out-of-service rail segments as for active rail segments. Secondary effects to wildlife habitat functions would result from the temporary loss of wetland that provides wildlife habitat function, or from canopy removal in forested wetlands as the canopy edge effects would extend further into the wetland. The change in wetland vegetation would reduce the effective habitat size for all species, more so for forest interior species. Areas of temporary impact would be restored but create the potential for establishment of invasive species such as common reed or reed-canary grass that reduce wetland habitat quality in the impacted area and can spread throughout the wetland. Where the wetland is a vernal pool, or contains vernal pool habitat, the same effects occur and further reduce the wildlife habitat functions.

Other Secondary and/or Indirect Effects

Other categories of secondary and/or indirect effects include effects caused by extending or relocating culverts that convey streams, and the potential effects of changes in stormwater discharge from the proposed commuter rail stations. Where culverts would be required to be extended or relocated, the changes to the wetland outlet have the potential to result in secondary effects to the physical as well as biological characteristics of wetlands. Changes to the outlet of a wetland could alter the duration or depth of flood storage, change discharge rates (that would affect downstream wetlands), or result in channel modifications upstream or downstream of the culvert.

Culverts are proposed to be retained without modification in the majority of areas, or reconstructed to meet to meet engineering requirements for operation of the South Coast Rail (per industry standards for railroad use) and, where appropriate (based on hydrology and ecological value), the Massachusetts Stream Crossing Standards.[34] Where culverts are proposed to be reconstructed to meet these standards, culvert extension is not proposed and the appropriate hydrological studies would be undertaken prior to final design to ensure that the upstream and downstream hydrology was not altered.

[34] River and Stream Crossing Partnership. 2011. Massachusetts River and Stream Crossing Standards. The University of Massachusetts- Amherst (College of Natural Sciences), The Nature Conservancy, Massachusetts Division of Ecological Restoration-Riverways Program, American Rivers, and others. August 2004; revised March 1, 2006; revised March 1, 2011; corrected January 31, 2012.

Effects of stormwater discharges on wetlands have been minimized since all stations have been designed to comply with the Massachusetts Stormwater Standards. Stormwater collection and treatment systems would reduce the discharge of total suspended solids (TSS) and other contaminants, and would reduce discharge rates through the use of infiltration basins and bioretention swales. However, increased flows into or through the wetland, and potential increased discharge of TSS and other contaminants, could affect stream channels through erosion and/or deposition, alter vegetation or facilitate the introduction of invasive species. Functions affected could include bank stabilization, sediment/toxicant retention, production export, and wildlife habitat. Stormwater discharge would be likely to affect up to ten wetlands.

Stoughton Alternative

As shown in Table 4.16-41, the majority of wetlands along either the active or inactive segments of the Stoughton alternative would experience negligible to minor impacts to functions and values. In most cases, the wetlands are relatively large in comparison to the area in which functions would be lost or altered, and there would be little overall effect on the ability of the wetland to provide these functions. As shown in the table, the functions most affected would be wildlife habitat, with 116 of the 144 wetlands providing this function affected. Most of these (77 percent) would experience negligible or minor impacts. Although wetlands along both the active and inactive segments would experience a decrease in their ability to support wildlife habitat functions, including rare species habitat, these changes would be greater in the inactive segments due to the barrier effect of the reconstructed tracks. The segment through the Hockomock Swamp would result in a minor effect on wildlife habitat through creation of a canopy gap although there would be no barrier to wildlife movement. The overhead catenary system required to provide electric rail service would affect 58 wetlands that provide visual or aesthetic value, a majority of the wetlands that provide this function.

Table 4.16-41 Secondary and/or Indirect Effects on Wetlands within 100 feet of the Rail Segments along the Stoughton Alternative[1]

		Negligible/Minor		Moderate/High		
Function	Total Wetlands[2]	Active	Out-of-Service	Active	Out-of-Service	Total[3]
Groundwater recharge/discharge	339	0	0	0	0	10
Floodflow alteration	112	33	18	9	8	68
Fish and shellfish habitat	84	16	15	0	0	32
Sediment/toxicant/pathogen retention	145	45	11	20	5	88

1 Includes all wetlands within 100 feet of the right-of-way
2 Wetlands that perform each function as a principal function
3 Includes wetlands that would receive stormwater discharge that are more than 100 feet from the right-of-way

Whittenton Alternative

As shown in Table 4.16-42, the majority of wetlands along either the active or inactive segments of the Whittenton alternative proposed commuter rail line would experience negligible to minor impacts to functions and values. In most cases, the wetlands are relatively large in comparison to the area in which functions would be lost or altered, and there would be little overall effect on the ability of the wetland to provide these functions. As shown in the table, the functions most affected would be wildlife habitat, with 113 of the 145 wetlands providing this function affected. Most of these (80 percent) would experience negligible or minor impacts. Although wetlands along both the active and inactive segments would experience a decrease in their ability to support wildlife habitat functions, including rare species habitat, these changes would be greater in the inactive segments due to the barrier effect of the reconstructed tracks. The segment through the Hockomock Swamp would result in a minor effect on wildlife habitat through creation of a canopy gap although there would be no barrier to wildlife movement.

Table 4.16-42 Secondary and/or Indirect Effects on Wetlands within 100 feet of the Rail Segments along the Whittenton Alternative[1]

Function	Total Wetlands[2]	Negligible/Minor Impacts		Moderate/High Impacts		Total Impacts
		Active	Out of Service	Active	Out of Service	
Groundwater recharge/discharge	333	-	3	-	1	14
Floodflow alteration	122	33	17	9	8	72
Fish and shellfish habitat	78	16	11	-	-	35

Endangered species habitat	102	27	12	4	22	69

1 Includes all wetlands within 100 feet of the right-of-way.
2 Wetlands that perform each function as a principal function.

As a result of the overhead catenary structures required to provide electric rail service, the overhead catenary system would affect 52 wetlands that provide visual or aesthetic value, a majority of which provide this function.

Along the Whittenton Branch, overall indirect or secondary impacts are generally small, due to the proportionately small direct impacts along the route. A large portion of one wetland, Wetland TWB-08.1, would be eliminated to construct the railroad. As described above, this is a disturbed, mainly unvegetated wetland that has developed within the right-of-way due to compression of soils from ATV and other use of the path, and provides little function or value. The remaining impacts to wetlands along

the Whittenton Branch are negligible or minor. The most affected wetland function is wildlife habitat, as barrier and noise effects along the currently inactive right-of-way could impact existing habitat or reduce the effective contiguous habitat size of wetlands. This effect is most likely to be seen in the approximately 0.3 mile section of the Whittenton Branch where the right-of-way branches off from the stone quarry access road. In this section, in the vicinity of Wetlands TWB 03.1 through TWB 01, both the western and eastern sides of the tracks have large areas of undeveloped land with only a narrow, mostly-vegetated path between them, whose size may be effectively reduced by constructing the railroad.

4.16.9.4 Temporary Construction-Period Impacts

Construction impacts associated with a transportation project are those impacts that are temporary or short term, and occur only during construction. This section provides an overview of construction impacts, and outlines mitigation measures that would be employed to reduce short term impacts related to construction.

Temporary Impacts

Temporary impacts that may occur along the right-of-way include work areas adjacent to the alignment, the placement of erosion control devices including hay bales and silt fence, and any indirect impact that could result from the migration of exposed soils. Erosion and sedimentation control plans would be required from the contractor prior to commencement of work that would include ground disturbance. The Stormwater Pollution Prevention Plan (SWPPP) required under the General Permit for Discharges From Construction Activities[35], effective February 16, 2012 and promulgated by the US Environmental Protection Agency must identify potential source areas and describe what measures would be employed as erosion control, sedimentation control, temporary stormwater management, dust control, and winter stabilization measures. Multiple Best Management Practices (BMPs) would be used in sensitive areas. Erosion control plans would also address any in-water work at stream crossing locations.

Because railroad equipment operates optimally on relatively level track segments, existing and proposed rail corridors are located in areas of flat topography commonly associated with wetland resource areas. Wetlands frequently occur at the toe of the embankment along the existing rail corridors within the project area. Any work that disturbs the toe of slope along the right-of-way typically involves some amount of temporary wetland impacts for slope stabilization, the placement of erosion controls and to provide a work zone for laborers and equipment. To calculate these impacts, an 8-foot temporary work zone strip was assumed to occur on either side of the existing or proposed right-of-way. This area would be returned to preconstruction conditions following the completion of work. Temporary impacts to wetlands would be mitigated for by returning the area to original grade following work and by seeding it with an appropriate seed mix for the area.

An erosion and sedimentation control program would be implemented to limit temporary impacts associated with migrating sediment during the construction phase of the project. These programs typically minimize exposed soil through sequencing and temporary stabilization, placing structures to minimize stormwater runoff and erosion, and establishing a vegetated cover or other forms of stabilization as soon as practicable.

---

[35] US Environmental Protection Agency. 2012. National Pollutant Discharge Elimination System General Permit for Discharges from Construction Activities. US EPA, April 16, 2013, <http://www.epa.gov/npdes/pubs/cgp2012_finalpermit.pdf> (April 25, 2013)

Bridges and Culverts

For bridges over waterways, the contractor would ensure that all construction is performed within the temporary and permanent impact limits set forth by the environmental permits. Any dewatering, if required, would also be performed in accordance with the environmental conditions and would be discharged to an adjacent upland area using appropriate BMPs such as filter bags, settling pools and sediment traps. No debris shall be allowed to enter the watercourse. For longer spans over watercourses, such as the Taunton River, it may be necessary for the work to be done using barges.

Culverts along the right-of-way were evaluated for their stability and effectiveness at conveying water across the existing rail bed. Where possible, culverts would be replaced to meet the new stream crossing standards. Other culvert crossings would be improved to the maximum extent practicable to more closely adhere to stream crossings standards. Where expansions and improvements are not possible, culverts would be replaced in-kind, or would be left in place. The design of each culvert would be evaluated during the final design process to assess and prevent potential adverse effects on hydrology, streamflow, and fisheries.

Where culvert and bridge work is proposed, coffer dams or other silt barriers would be used to prevent debris and sediment from entering the work area and migrating downstream. Where necessary, water would be pumped around the culvert or the bridge structure during work to limit downstream disturbance. Following completion of work, areas adjacent to bridge abutments and culvert headwalls would be restored to its original condition through planting and grading.

Temporary impacts at bridges and culverts would occur on either end of the structure as a result of the temporary work zone that would be required in order for equipment and personnel to install the structure. Additional temporary impacts would occur through the installation of coffer dams, erosion control barriers, equipment movement and other construction period activities.

4.16.9.5 Summary of Direct Impacts by Alternative

This section and Table 4.16-43 summarizes the total potential impact to wetlands that would occur under each of the alternatives inclusive of stations and layover facilities.

No-Build (Enhanced Bus) Alternative

The No-Build Alternative would not impact wetlands.

Stoughton Electric Alternative

In terms of Commonwealth of Massachusetts resources, the Stoughton Electric Alternative would permanently impact 16,813 linear feet of Bank, 9.6 acres of BVW, 6.7 acres of BLSF, and 7.9 acres of new development Riverfront Area (Table 4.16-43). The largest impacts would occur in Raynham (1.3 acres of BVW) and Stoughton (2.0 acres of BVW), particularly south of the former Greyhound Park where the corridor forms the border of the Hockomock Swamp and then crosses through Pine Swamp. These impacts would occur in and along the edge of the abandoned railroad embankment. Minor impacts would occur along the components of the Southern Triangle, along the remainder of the Stoughton Line north of the Hockomock Swamp, at the Canton, East Taunton, Easton Village, and Raynham Park stations, and at traction power stations Stoughton TPSS-2 in New Bedford, Stoughton PS-1 in Easton, and Stoughton SWS-1 in Canton. Impacts would be closely evaluated during final design and would be minimized or avoided to the maximum extent practicable. Potential permanent wetland impacts along the Stoughton Line include 0.2 acre within the Hockomock Swamp ACEC. Indirect impacts within the

Hockomock swamp would be minimal due to the existing rail bed and the proposed elevated trestle that would span 1.8 miles of the Hockomock swamp. The elevated trestle would facilitate free wildlife passage across the proposed route, as well as maintain the current hydrology of the area. Additionally, approximately 1.5 acres of ORWs would be impacted along the Stoughton Electric Alternative.

Federally regulated waters of the United State include tributaries to navigable waters of the United States and their adjacent wetlands. For purposes of this FEIS, waters of the United States are divided into waterbodies/waterways and vegetated wetlands. The Stoughton Electric Alternative would result in the permanent loss of 12.3 acres of waters of the United States, including 1.9 acres of waterbodies/waterways and 10.4 acres of federally regulated wetlands.

Table 4.16-43 Permanent Wetland Resource Impacts by Alternative[1]

Alternative	Total
Stoughton Electric Alternative	
a. Massachusetts WPA Resources:	
Bank (lf)	16,813
Land Under Water (ac)	1.9
Bordering Vegetated Wetland (ac)	9.6
Wetlands (BVW) within ACECs (ac)	0.2
Outstanding Resource Waters (ac)	1.5
Bordering Land Subject to Flooding (ac)	6.7
Riverfront Area (ac)[2]	7.9
b. Waters of the United States:	
Waterbodies/Waterways (ac)	1.9
Vegetated Wetlands (ac)	10.4
Whittenton Electric Alternative	
a. Massachusetts WPA Resources:	
Bank (lf)	16,581
Land Under Water (ac)	1.8
Bordering Vegetated Wetland (ac)	8.4
Wetlands (BVW) within ACECs (ac)	0.2
Outstanding Resource Waters (ac)	1.1
Bordering Land Subject to Flooding (ac)	5.0
Riverfront Area (ac)[2]	7.8
b. Waters of the United States:	
Waterbodies/Waterways (ac)	1.8
Vegetated Wetlands (ac)	9.4

1 Figures are inclusive of stations and layovers.
2 New Development of Riverfront Area – the loss of on naturally vegetated lands within RA, excluding railroad track and ballast

Stoughton Diesel Alternative

Impacts to wetlands for the Stoughton Diesel Alternative are similar to the impacts identified above for the Stoughton Electric Alternative. The diesel alternative does not require traction power substations and would result in approximately 0.01 acre of permanent wetland impacts less than the Stoughton

Electric Alternative along the New Bedford Main Line. All other impacts are the same as those estimated for the remainder of Stoughton Electric Alternative.

Whittenton Electric Alternative

The Whittenton Electric Alternative would permanently impact the following resources regulated by the Commonwealth: 16,581 linear feet of Bank, 8.4 acres of BVW, 5.0 acres of BLSF, and 7.8 acres of new development Riverfront Area (Table 4.16-43). By town, the largest amount of impacts would occur in Berkley (1.4 acres of BVW) and Stoughton (2.0 acres).This alternative would leave the Stoughton Line corridor at Raynham Junction and instead would follow the Whittenton Branch to the Attleboro Secondary. This diversion would avoid wetland impacts in Pine Swamp. As with the Stoughton Alternative, the majority of impacts would occur in and along the edge of the abandoned railroad embankments. Minor impacts would occur along the components of the Southern Triangle, along the remainder of the Stoughton Line north of the Hockomock Swamp, at the Canton, East Taunton, Easton Village, and Raynham Park stations, and at traction power stations Whittenton TPSS-2 in New Bedford, Whittenton PS-1 in Easton, and Whittenton SWS-1 in Canton. Impacts would be avoided or minimized during final design to the maximum extent practicable.

Potential permanent wetland impacts along the Stoughton Line segment of this alternative include 0.2 acre within the Hockomock Swamp ACEC. Indirect impacts within the Hockomock swamp would be minimal due to the existing rail bed and the proposed elevated trestle that would span 1.8 miles of the Hockomock swamp. The elevated trestle would facilitate free wildlife passage across the proposed route, as well as maintain the current hydrology of the area. Additionally, approximately 1.1 acres of ORWs would be impacted along the Whittenton Electric Alternative.

The Whittenton Electric Alternative would result in the permanent loss of 11.2 acres of waters of the United States, including 1.8 acres of waterbodies/waterways and 9.4 acres of federally regulated wetlands.

Whittenton Diesel Alternative

Impacts to wetlands for the Whittenton Diesel Alternative are similar to the impacts identified above for the Whittenton Electric Alternative. The diesel alternative does not require traction power substations and would result in approximately 0.01 acre of permanent wetland impacts less than the Whittenton Electric Alternative along the New Bedford Main Line. All other impacts are the same as those estimated for the remainder of Whittenton Electric Alternative.

4.16.10 Mitigation

This section provides a description of wetland mitigation measures (wetland creation and restoration, and land preservation) proposed to minimize impacts and restore wetland resource areas functions and values. This section addresses both the Stoughton and Whittenton Alternatives. The two alternatives are identical except for a 5.8 mile stretch of tracks between Raynham Junction and Weir Junction in Raynham and Taunton, resulting in slightly lower wetland impacts along the Whittenton Alternative. Mitigation goals are considered based on the impacts for each alternative individually.

The Secretary’s Certificate focused on wetland creation, restoration, and land acquisition as mitigation for wetland and biodiversity impacts. Specific requirements of the Certificate included:

- The FEIR should identify targeted lands for acquisition by MassDOT as mitigation for the cumulative and indirect impacts of the project.

- A variance from the Wetlands Protection Act (WPA) regulations is required for the project's impacts to rare species. One concrete way for MassDOT to translate its smart growth planning into resource protection is to fund for conservation-protected targeted acquisition of parcels in Priority Protection Areas (PPAs) that are important to meet the long-term net benefit to rare species and preserve land with a high Index of Ecological Integrity. The FEIR should identify targeted sites for acquisition and describe in detail how the proposed land acquisition will offset direct and indirect impacts of the project.

- MassDOT should consult with EEA agencies to identify and protect areas critical to preserving the integrity of existing and valuable ecosystems. MassDOT should also partner with local Conservation Commissions and Planning Boards, regional planning agencies, and non-profit land trust/conservation organizations in a coordinated effort to adopt land preservation strategies that will stem wetland habitat fragmentation. The FEIR should clearly identify MassDOT's commitments to acquire land that meets the project's mitigation requirements and longer-term smart growth plans.

- The FEIR mitigation plan should include the following:

  - A 2:1 ratio for Bordering Vegetated Wetland (BVW) mitigation (at a minimum), at least 1:1 for all other wetlands. Where the USACE requires higher ratios (e.g., for forested wetlands) the mitigation plan should reflect the federal requirements also;

  - An evaluation of potential for restoration/preservation of Atlantic white cedar (*Chamaecyparis thyoides*) wetlands;

  - Meaningful Riverfront Area improvements and/or restoration to mitigate for riverfront impacts;

  - On-site elevation-specific compensatory storage for lost flood storage, or if such compensatory storage cannot be provided, demonstrate an insignificant increase in flooding, demonstrate that any incremental increase in flooding could be contained on the Proponent's property, or acquire flood easements;

  - Wetland restoration within the Hockomock Area of Critical Environmental Concern (ACEC).

- The FEIR should document with a high level of assurance that land identified for preservation, restriction or relocation/restoration to be taken by eminent domain can actually be acquired and will satisfy mitigation goals. As part of the assurances, additional mitigation areas should be identified as fall-back options in the event the primary mitigation goals are not achieved.

- MassDOT should consult with the Interagency Coordinating Group (ICG) for input on a draft mitigation plan including the methodology to identify appropriate mitigation for fragmentation impacts and the analysis of mitigation opportunities in the context of fulfilling

mitigation objectives. MassDOT should expand its outreach efforts during FEIR preparation to obtain public input on draft mitigation plans.

- The draft mitigation plan presented in the FEIR should clearly identify the impacts to be mitigated, for example specific resources, functions and values, amounts and types of impacts, etc. The plan should describe specific mitigation objectives and include an evaluation of mitigation options to determine which sites and mitigation measures perform best overall in terms of fulfilling mitigation objectives.

4.16.10.1 Avoidance and Minimization

State and Federal Guidelines

MassDEP has published a guidance document for wetland mitigation that discusses avoidance and minimization. The MassDEP guidance document avoids relying solely on replication for loss of wetlands, in light of evidence to suggest that poorly designed or constructed replication projects can fail to become new wetland areas as they were designed to do. The guidance document establishes avoidance as the first consideration for a project, using "evaluation of reasonable project designs that attempt to locate projects away from wetlands in order to avoid impacts." After considering all reasonable avoidance, minimization measures can be taken such as "steepening slopes, and, depending on the scale/nature of the project, construction of retaining walls or bridge spans to reduce wetland impacts." Only after avoidance and minimization have been applied to the fullest extent practicable should replication be considered for mitigation purposes. The use of avoidance and demonstrating no reasonable alternatives that would allow the project to proceed in compliance with the regulations one of the criteria required to obtain a Variance from the regulations.

Federal guidelines about avoidance and minimization are presented in the Section 404(b)(1) "Guidelines for Specification of Disposal Sites for Dredged or Fill Material." A Memorandum of Agreement (MOA) between the USACE and USEPA sets forth a sequence approach for evaluating wetland impacts that calls first for avoidance, then minimization, and finally compensatory mitigation for impacts. The goal of the guidelines and MOA is to establish no net loss of wetland functions and values.

Avoidance

Avoidance of wetland impacts was considered when designing the track layout for the alternatives described below. When possible, the track was kept within the existing footprint, elevated by trestle, and/or re-routed away from large areas of wetland impact. Retaining walls were also included, to the maximum extent practicable in this design stage, in track and layout design to avoid additional impacts associated with large grading footprints. Complete avoidance of all wetland impacts would only be possible through the No Build Alternative, which does not meet the project purpose. The sections below describe specific steps taken towards avoidance.

The Stoughton Electric Alternative would provide commuter rail service to South Station using the Northeast Corridor, the Stoughton Line, the New Bedford Main Line, and the Fall River Secondary. This alternative requires reconstructing track on the Southern Triangle segments and reconstructing freight rail and existing inactive rail along the Stoughton Line in Stoughton, Easton, Raynham, and Taunton, as well as the Southern Triangle. The routes were selected to avoid wetland impacts associated with the design and construction of a new right-of-way. Impacts are unavoidable along this alternative because wetlands are directly adjacent to existing track and, in some locations, on the rail bed itself.

Several portions of the Stoughton Alternative would use retaining walls to avoid wetland impacts. Impacts to 28 wetlands would be minimized by retaining walls along the Stoughton Alternative, particularly at wetlands ST 7A in Stoughton. In addition to the proposed retaining walls, a proposed trestle through the Hockomock Swamp would reduce direct wetland impacts. The proposed track design includes approximately 8,500 feet of elevated trestle along the track segment that crosses the Hockomock Swamp through Raynham and Easton. Along this portion of the right-of-way, the track would be supported by pilings. The elevated track design would avoid indirect impacts such as hydrologic movement, animal crossings, and wetland connectivity. The reconstruction of the existing right-of-way would occur within the existing footprint to the maximum extent practicable to further avoid wetland impacts.

Both portions of the Southern Triangle would use retaining walls to avoid wetland impacts. The Fall River Secondary and New Bedford Main Line would use retaining walls in ten locations to avoid additional impacts in eleven wetlands.

Station and layover facilities were chosen from a large pool of potential sites and were selected to avoid wetland impacts to the extent practicable. Neither of the proposed layover sites would affect vegetated wetlands. Proposed stations at North Easton, Easton Village, Raynham Park, Taunton, Fall River Depot, Battleship Cove, and Whale's Tooth would avoid wetlands.

The Whittenton Alternative is different from the Stoughton Alternative only along a portion of right-of-way between Raynham Junction and Weir Junction, a length of approximately 5.8 miles. The Whittenton and Stoughton Alternatives run the same course on the Stoughton Line from Canton to Raynham Junction. The New Bedford Main Line and the Fall River Secondary are also identical for both alternatives. The Whittenton Alternative, using the Whittenton Branch and a portion of the Attleboro Secondary, avoids some wetland areas associated with Pine Swamp that would be impacted by the Stoughton Alternative. Structural avoidance measures such as retaining walls would be used in the same manner as on the Stoughton Alternative, and the trestle through the Hockomock Swamp would also remain part of the design.

Minimization

The conceptual alternatives evaluated in this report include design features that were selected to minimize wetland impacts, such as the use of single track segments where possible to minimize widening of the right-of-way and locating railroad passing sidings in adjacent uplands rather than in wetlands. Wetland impacts would be further evaluated during final design. As part of that process, additional steps would be taken to minimize specific impacts along the preferred alternative, such as tightening side slopes and using retaining walls to reduce the overall footprint associated with the proposed work.

Proposed track design and layout in conjunction with construction practices would minimize impacts to wetlands to the extent practicable. In the final design process, impacts would be further minimized by design modifications including the use of steep slopes and retaining walls when the right-of-way is elevated above wetland resource areas. For example, use of a vertical retaining wall could reduce wetland impacts by 50 percent or more over a sloped embankment. Minimization of impacts to wetland resource areas has occurred since the DEIS/DEIR, which estimated a total of 11.9 acres of wetland impact BVW and LUW along the right-of-way for the Stoughton Alternative. The current estimate of the impacts to these resource areas from the Stoughton Alternative is 11.7 acres and 10.6 acres from the

Whittenton Alternative. Additional measures to minimize wetland impacts will be considered as the project design advances.

Wetland impacts at station locations were minimized by designing station layouts around wetland resources and by selecting station locations where the smallest number of impacts would occur. Within the footprint of the selected sites, the configuration of station amenities and storage tracks were modified to minimize impacts that could not otherwise be avoided.

4.16.10.2 Mitigation Goals and Objectives

Introduction

This section identifies the goals of wetland mitigation, based on regulatory requirements and wetland impacts previously presented. The objective of the mitigation design is to replace the functions and values provided by wetlands that would be altered during reconstruction or construction of the preferred alternative. The design of wetland replacement areas will incorporate, to the extent possible, functions and values that have been lost through wetland impacts. Wetlands would be designed to conform to the guidelines developed by the USACE and would meet the performance standards contained in the WPA regulations to the extent practicable. This would include providing minimums of 2:1 replacement for BVW, and 3:1 replacement for lost federally regulated forested wetlands. Bank and BLSF would be replaced at a 1:1 ratio and would be replaced in kind to the extent practicable. Compensatory mitigation areas would also be designed to provide vernal pool habitat.

Replacement of impacted wetlands, along with their functions and values would be achieved through several approaches including: restoring former wetland areas that were filled or otherwise altered and are currently upland; restoring functions to an existing, degraded wetland; enhancing wetland functions; and contributions to a mitigation bank or in lieu fee program, if one were available in the same watershed.

A watershed approach to wetland mitigation has been taken to compensate for direct impacts associated with the proposed work. Permanent impacts associated with each alternative were identified by watershed and by cover type. Proposed mitigation would seek to mitigate for impacted wetland cover types within the each watershed where impact would occur. USACE guidelines for mitigation ratios were followed in conjunction with guidelines established by MassDEP. Establishment of wetlands under USACE guidelines also mitigate for secondary impacts of the project. The tables in the remainder of this section show mitigation goals required under both state and federal guidelines.

The following sections present the wetland mitigation goals under both state and federal guidelines for both the Stoughton and Whittenton Alternatives. The following information is based on the current level of design for the project. At later design stages, detailed wildlife habitat assessments would be conducted of both impact areas and proposed mitigation areas. Mitigation goals, plans, and design may be adjusted based on the results of these assessments.

Massachusetts Wetlands Protection Act

On similar projects, MassDEP has required a 2:1 replacement ratio for BVW as part of a WPA variance. MassDEP typically seeks strict replication by requiring mitigation sites to be on site or adjacent to the impacted site, in the same watershed, with the same elevation, habitat type, hydrological connection, ecological functions, and other key characteristics. BLSF requires mitigation at a 1:1 ratio to provide compensatory flood storage. This would be designed during the final design phase and would follow the

performance standards for BLSF replacement to the extent practicable. Impacts to LUW (shown as having a cover type of OW) do not have an associated replacement ratio under the WPA. MassDEP has indicated that 1:1 replacement of LUW areas would constitute sufficient mitigation for this resource area.

Stoughton Electric Alternative

The Stoughton Alternative would result in the alteration of approximately 16,813 linear feet of Bank, of which the majority are intermittent or perennial streams that flow on the railroad bed due to blocked drainage ditches. Most of these streams lack vegetation, and do not provide important wildlife habitat. Impacts will be mitigated at a 1:1 ratio, on-site, by restoration of drainage ditches. One drainage diversion in Raynham has been determined to be a perennial stream with vegetated banks.

The project would result in the loss of 9.6 acres of BVW, which would require a 2:1 mitigation ratio, for a total replacement of 19.2 acres. Areas of temporary alteration (5.4 acres) would be restored in place. The project would also result in the loss of 1.9 acres of LUW, of which the majority is associated with the Raynham perennial stream. An additional 0.3 acre of LUW is within Terry Brook Pond in Freetown.

A total of 6.7 acres of BLSF would be impacted by the Stoughton Electric Alternative. Mitigation would be provided for the loss of compensatory flood storage (to be determined during subsequent final design phases of the project) and for the loss of wildlife habitat, at a 1:1 ratio. The project would result in the loss of 7.9 acres of vegetation within Riverfront Area. Further analysis is required to determine if any of the 22 affected areas provide important wildlife habitat and would require compensatory mitigation. Table 4.16-44 presents the wetland mitigation goals for impacts to state resource areas for the Stoughton Electric Alternative.

Table 4.16-44 Wetland Mitigation Goals–State Resource Areas (Stoughton Electric Alternative)

Municipality	Bank (lf)	BVW (ac)	LUW (ac)	BLSF1 (ac)	RA2 (ac)
Canton	90	<0.1	-	0.9	0.4
Stoughton	539	2.0	-	0.7	-
Easton	5,423	0.3	-	0.8	0.8
Raynham	6,994	1.3	1.5	2.9	2.5
Taunton	468	1.5	-	0.8	1.3
Berkley	233	1.4	-	0.2	1.1
Lakeville	606	0.8	-	0.1	0.8
Freetown	2,460	1.0	0.3	0.3	1.0
New Bedford	-	1.2		<0.1	-
Fall River	-	-		-	-
Total 1:1 Mitigation[3]	16,813	9. 6	1.9	6.7	7.9[4]
Total 2:1 Mitigation		19.2			

Wetland Classifications: BVW = Bordering Vegetated Wetland, LUW=Land Under Water, BLSF = Bordering Land Subject to Flooding, ILSF = Isolated Land Subject to Flooding, RA = Riverfront Area.

1 BLSF and ILSF were withdrawn from the ANRAD applications for the municipalities of Stoughton and Easton, and therefore neither resource area was confirmed by the Conservation Commissions from either municipality. Information for these resource areas is presented here for informational purposes and is approximate.

2 New Development of Riverfront Area – the loss of naturally vegetated lands within RA, excluding railroad track and ballast.

3 Total 1:1 Mitigation figures also equal the total impact to wetland resource areas.

4 Requires replacement of important wildlife habitat, rather than acreage of equivalent land.

Whittenton Electric Alternative

The Whittenton Alternative would result in the alteration of approximately 16,581 linear feet of Bank, of which the majority are intermittent or perennial streams that flow on the railroad bed due to blocked drainage ditches. Most of these streams lack vegetation, and do not provide important wildlife habitat. Impacts will be mitigated at a 1:1 ratio, on-site, by restoration of drainage ditches. One drainage diversion in Raynham has been determined to be a perennial stream with vegetated banks.

The project would result in the loss of 8.4 acres of BVW, which would require a 2:1 mitigation ratio, for a total replacement of 16.8 acres. Areas of temporary alteration (4.7 acres) would be restored in place. The project would also result in the loss of 1.8 acres of LUW, of which the majority is associated with the Raynham perennial stream. An additional 0.3 acre of LUW is within Terry Brook Pond in Freetown.

A total of 5.0 acres of BLSF would be impacted by the Whittenton Alternative. Mitigation would be provided for the loss of compensatory flood storage (to be determined during subsequent final design phases of the project) and for the loss of wildlife habitat, at a 1:1 ratio. The project would result in the loss of 8.3 acres of vegetation within Riverfront Area. Further analysis is required to determine if any of the 22 affected areas provide important wildlife habitat and would require compensatory mitigation. Table 4.16-45 presents the wetland mitigation goals for impacts to state resource areas for the Whittenton Alternative.

Table 4.16-45 Wetland Mitigation Goals–State Resource Areas (Whittenton Alternative)

Municipality	Bank (lf)	BVW (ac)	LUW (ac)	BLSF1 (ac)	RA2 (ac)
Canton	90	<0.1	-	0.9	0.4
Stoughton	539	2.0	-	0.7	-
Easton	5,423	0.3	-	0.8	0.8
Raynham	6,773	0.5	1.5	1.2	2.3
Taunton	457	1.2	-	0.8	1.4
Berkley	233	1.4	-	0.2	1.1
Lakeville	606	0.8	-	0.1	0.8
Freetown	2,460	1.0	0.3	0.3	1.0
New Bedford	-	1.2		<0.1	-
Fall River	-	-		-	-
Total 1:1 Mitigation	16,581	8.4	1.8	5.0	7.8[4]
Total 2:1 Mitigation		16.8			

Wetland Classifications: BVW = Bordering Vegetated Wetland, LUW=Land Under Water, BLSF = Bordering Land Subject to Flooding, ILSF = Isolated Land Subject to Flooding, RA = Riverfront Area.

1 BLSF and ILSF were withdrawn from the ANRAD applications for the municipalities of Stoughton and Easton, and therefore neither resource area was confirmed by the Conservation Commissions from either municipality. Information for these resource areas is presented here for informational purposes and is approximate.

2 New Development of Riverfront Area – the loss of naturally vegetated lands within RA, excluding railroad track and ballast.

3 Total 1:1 Mitigation figures also equal the total impact to wetland resource areas.

4 Requires replacement of important wildlife habitat, rather than acreage of equivalent land.

Federal Wetlands

The following sections present the wetland mitigation goals under federal guidelines for both permanent and temporary impacts for both the Stoughton and Whittenton Alternatives.

Stoughton Electric Alternative

The following sections present the wetland mitigation goals under federal guidelines for both permanent and temporary impacts, and presents mitigation goals by watershed, for the Stoughton Electric Alternative.

Permanent Impacts—The Stoughton Alternative would result in the loss of 10.4 acres of vegetated jurisdictional wetlands in three primary cover types (palustrine emergent wetland, palustrine scrub-shrub swamp, and palustrine wooded swamp). The first two cover types require mitigation at a 2:1 ratio (assuming restoration), while wooded swamp requires a higher mitigation ratio of 3:1 (assuming restoration). The total minimum area required for mitigation (as restoration) of these vegetated wetlands would be 31.3 acres. The project would also result in the loss of 1.9 acres of Open Water, which would be mitigated at a 1:1 ratio. The majority (1.5 acres) of Open Water is associated with the Raynham perennial stream. An additional 0.3 acre is within Terry Brook Pond in Freetown. Table 4.16-46 establishes goals for mitigation of impacts to federal jurisdictional wetlands for the Stoughton Electric Alternative, based on the ratios contained in the USACE New England District mitigation guidance.

Table 4.16-46 Summary of Federal Mitigation Goals by Cover Type–Permanent Impacts (acres) (Stoughton Electric Alternative)

Municipality	Total Impact	OW	PEM–Shallow Marsh	PEM–Deep Marsh	PSS–Scrub-Shrub	PFO–WSD	PFO–WSM
Canton	<0.1	-	-	-	-	<0.1	-
Stoughton	2.1	-	<0.1	-	-	2.0	-
Easton	0.4	-	-	<0.1	0.3	0.1	-
Raynham	2.9	1.5	-	<0.1	<0.1	1.3	<0.1
Taunton	1.9	-	0.6	-	-	1.3	-
Berkley	1.5	-	-	-	0.2	1.1	0.1
Lakeville	0.8	-	-	-	0.1	0.7	-
Freetown	1.4	0.3	<0.1	-	0.2	0.9	-
New Bedford	1.2		0.4	-	<0.1	0.8	<0.1
Fall River	<0.1		-	-	-	<0.1	-
Total Impact	12.3	1.9	1.0	<0.1	0.9	8.3	0.2
Minimum Mitigation Ratio[1]		1:1	2:1	2:1	2:1	3:1	3:1
Total Mitigation	31.3	1.9	Total PEM: 2.1		1.8	Total PFO: 25.5	

Notes: Cowardin Types: OW = Open Water, PEM = Palustrine Emergent, PSS = Palustrine Scrub/Shrub PFO = Palustrine Forested.
PFO Subgroups: WSD = Wooded Swamp Deciduous, WSM = Wooded Swamp Mixed trees.
1 Assumes Restoration as the mitigation method.

Temporary Impacts—As shown in Table 4.16-47, the Stoughton Alternative would result in the temporary alteration of 5.6 acres of vegetated jurisdictional wetlands in three primary cover types (palustrine emergent wetland, palustrine scrub-shrub swamp, and palustrine wooded swamp). The first two cover types require mitigation at a 1:1 ratio (restoration in situ), while wooded swamp requires a higher mitigation ratio of 1.5:1 (restoration in situ plus additional mitigation to compensate for longer-term changes in vegetative cover type and wildlife habitat functions). Temporary impacts would also occur to 0.3 acre of Open Water. Since the majority of the Open Water area is composed of unvegetated banks of intermittent streams along the right-of-way and areas where culverts are being replaced or upgraded, mitigation is not proposed for these areas. The total area required for mitigation (as restoration) would be 8.1 acres. About 5.7 acres of this mitigation can be accomplished by restoration in situ; the remaining 2.4 acres of mitigation will be added to the mitigation goals for permanent impacts.

Table 4.16-47 Summary of Federal Mitigation by Cover Type–Temporary Impacts (acres) (Stoughton Electric Alternative)

Municipality	Total Impact	OW	PEM– Shallow Marsh	PEM– Deep Marsh	PSS– Scrub-Shrub	PFO– WSD	PFO– WSM
Canton	0.1	<0.1	<0.1	-	<0.1	<0.1	-
Stoughton	0.1	-	<0.1	-	-	0.1	-
Easton	0.2	-	-	<0.1	<0.1	0.1	-
Raynham	1.0	0.1	-	<0.1	0.1	0.8	<0.1
Taunton	1.4	<0.1	0.2	-	-	1.2	-
Berkley	1.0	-	-	-	0.1	0.8	<0.1
Lakeville	0.6	<0.1	-	-	<0.1	0.5	-
Freetown	0.7	0.1	0.1	-	<0.1	0.4	-
New Bedford	0.8		<0.1	-	0.1	0.6	0.1
Fall River	0.1		-	-	-	0.1	-
Total Impact	5.9	0.3	0.3	0.1	0.4	4.7	0.1
Minimum Mitigation Ratio[1]			1:1	1:1	1:1	1.5	1.5
Total Mitigation	8.1[2]	0.0	Total PEM: 0.4		0.4	Total PFO: 7.3	

Notes: Cowardin Types: OW = Open Water, PEM = Palustrine Emergent, PSS = Palustrine Scrub/Shrub PFO = Palustrine Forested.
PFO Subgroups: WSD = Wooded Swamp Deciduous, WSM = Wooded Swamp Mixed trees.
1 Assumes all temporary impacts restored in place. Forested wetland (PFO) requires a higher ratio due to temporal change in wildlife habitat function.
2 Includes 5.6 acres of restoration in situ and 2.4 acres to be added to the mitigation goals for permanent impacts.

Mitigation Goals by Watershed—Compensatory mitigation for the loss of vegetated wetlands would be conceived with the overall goal to distribute mitigation among the four watersheds comprising the project area, as shown in Table 4.16-48. Under this general scenario, small areas of mitigation would be in the Neponset River Watershed and the Narragansett Bay watershed. The majority of the mitigation (88 percent) would be in the Taunton River Watershed, while approximately 12 percent would be allocated to the Buzzards Bay watershed. The mitigation goals shown in Table 4.16-48 include the mitigation goals for permanent impacts to vegetated wetlands and waterways (31.3 acres based on a permanent impact of 12.3 acres) as well as those temporary impacts not restored in situ (2.4 acres total). About 2.1 acres of restoration for temporary impacts would be in the Taunton River watershed and 0.3 acre would be in the Buzzards Bay watershed.

Table 4.16-48 Mitigation Goals by Watershed (Federal Wetlands/Waterways) for Stoughton Electric Alternative

Watershed	Impact Amount	Percentage
Neponset River	<0.1 ac	<1%
Taunton River	11.0 ac	88%
Buzzards Bay	1.2 ac	11%
Narragansett/Mt. Hope Bay	<0.1 ac	<1%
Totals	12.3 ac	33.7 ac

Whittenton Electric Alternative

The following sections present the wetland mitigation goals under federal guidelines for both permanent and temporary impacts, and presents mitigation goals by watershed, for the Whittenton Alternative.

Permanent Impacts—The Whittenton Alternative would result in the loss of 9.4 acres of vegetated jurisdictional wetlands in three primary cover types (palustrine emergent wetland, palustrine scrub-shrub swamp, and palustrine wooded swamp). The first two cover types require mitigation at a 2:1 ratio (assuming restoration), while wooded swamp requires a higher mitigation ratio of 3:1 (assuming restoration). The total minimum area required for mitigation (as restoration) of these vegetated wetlands would be 26.6 acres. The project would also result in the loss of 1.8 acres of Open Water, which would be mitigated at a 1:1 ratio. The majority (1.5 acres) of Open Water is associated with the Raynham perennial stream. An additional 0.3 acre is within Terry Brook Pond in Freetown. Table 4.16-49 establishes goals for mitigation of impacts to federal jurisdictional wetlands for the Whittenton Alternative, based on the ratios contained in the USACE's New England District mitigation guidance.

Table 4.16-49 Summary of Federal Mitigation Goals by Cover Type–Permanent Impacts (acres) (Whittenton Alternative)

Municipality	Total Impact	OW	PEM–Shallow Marsh	PEM–Deep Marsh	PSS–Scrub-Shrub	PFO–WSD	PFO–WSM
Canton	<0.1	-	-	-	-	<0.1	-
Stoughton	2.1	-	<0.1	-	-	2.0	-
Easton	0.4	-	-	<0.1	0.3	0.1	-
Raynham	2.1	1.5	-	-	<0.1	0.5	-
Taunton	1.6	-	0.1	-	-	1.5	-
Berkley	1.5	-	-	-	0.2	1.1	0.1
Lakeville	0.8	-	-	-	0.1	0.7	-
Freetown	1.4	0.3	<0.1	-	0.2	0.9	-
New Bedford	1.2		0.4	-	<0.1	0.8	<0.1
Fall River	<0.1		-	-	-	<0.1	-
Total Impact	11.2	1.8	0.6	<0.1	0.9	7.7	0.2
Minimum Mitigation Ratio[1]		1:1	2:1	2:1	2:1	3:1	3:1
Total Mitigation	28.4	1.8	Total PEM: 1.2		1.8	Total PFO: 23.6	

Notes: Cowardin Types: OW = Open Water, PEM = Palustrine Emergent, PSS = Palustrine Scrub/Shrub PFO = Palustrine Forested.
PFO Subgroups: WSD = Wooded Swamp Deciduous, WSM = Wooded Swamp Mixed trees.
1 Assumes Restoration as the mitigation method.

Temporary Impacts—As shown in Table 4.16-50, the Whittenton Alternative would result in the temporary alteration of 4.9 acres of vegetated jurisdictional wetlands in three primary cover types (palustrine emergent wetland, palustrine scrub-shrub swamp, and palustrine wooded swamp). The first two cover types require mitigation at a 1:1 ratio (restoration in situ), while wooded swamp requires a higher mitigation ratio of 1.5:1 (restoration in situ plus additional mitigation to compensate for longer-term changes in vegetative cover type and wildlife habitat functions). Temporary impacts would also occur to 0.2 acre of Open Water. Since the majority of the Open Water area is comprised of unvegetated banks of intermittent streams along the right-of-way and areas where culverts are being replaced or upgraded, mitigation is not proposed for these areas. The total area required for mitigation

(as restoration) would be 7.0 acres. About 4.8 acres of this mitigation can be accomplished by restoration in situ; the remaining 2.2 acres of mitigation will be added to the mitigation goals for permanent impacts.

Table 4.16-50 Summary of Federal Mitigation by Cover Type–Temporary Impacts (acres) (Whittenton Alternative)

Municipality	Total Impact	OW	PEM– Shallow Marsh	PEM– Deep Marsh	PSS– Scrub-Shrub	PFO– WSD	PFO– WSM
Canton	0.1	<0.1	<0.1	-	<0.1	<0.1	-
Stoughton	0.1	-	<0.1	-	-	0.1	-
Easton	0.2	-	-	<0.1	<0.1	0.1	-
Raynham	0.4	<0.1	-	<0.1	0.1	0.4	-
Taunton	1.1	-	0.1	-	-	1.1	-
Berkley	1.0	-	-	-	0.1	0.8	<0.1
Lakeville	0.6	<0.1	-	-	<0.1	0.5	-
Freetown	0.7	0.1	0.1	-	<0.1	0.4	-
New Bedford	0.8		<0.1	-	0.1	0.6	0.1
Fall River	0.1		-	-	-	0.1	-
Total	5.1	0.2	0.3	<0.1	0.3	4.1	0.1
Minimum Mitigation Ratio[1]			1:1	1:1	1:1	1.5	1.5
Total Mitigation	7.0	0.0	Total PEM: 0.3		0.3	Total PFO: 6.4	

Notes: Cowardin Types: OW = Open Water, PEM = Palustrine Emergent, PSS = Palustrine Scrub/Shrub
PFO = Palustrine Forested.
PFO Subgroups: WSD = Wooded Swamp Deciduous, WSM = Wooded Swamp Mixed trees.

1 Assumes all temporary impacts restored in place. Forested wetland (PFO) requires a higher ratio due to temporal change in wildlife habitat function.

2 Includes 5.0 acres of restoration in situ and 2.2 acres to be added to the mitigation goals for permanent impacts.

Mitigation Goals by Watershed—Compensatory mitigation for the loss of vegetated wetlands would be distributed among the four watersheds comprising the project area, as shown in Table 4.16-51. A small amount of mitigation (<0.1 acre) would be in the Neponset River Watershed and (0.2 acre) in the Narragansett Bay watershed. The majority of the mitigation (86 percent) would be in the Taunton River Watershed, while approximately 12 percent would be allocated to the Buzzards Bay watershed. The mitigation goals shown in Table 4.16-51 include the mitigation goals for permanent impacts (11.2 acres total) as well as those temporary impacts not restored in situ (2.2 acres total), allocated by watershed. About 2.0 acres of restoration for temporary impact would be in the Taunton River watershed and 0.2 acre would be in the Buzzards Bay watershed.

Table 4.16-51 Mitigation Goals by Watershed (Federal Wetlands/Waterways) (Whittenton Alternative)

Watershed	Permanent Impacts	Mitigation
Neponset River	<0.1 ac	<1%
Taunton River	9.9 ac	86%
Buzzards Bay	1.7 ac	12%
Narragansett/Mt. Hope Bay	0.2 ac	1%
Totals	11.2 ac	31.0 ac

Functions and Values

Wetland mitigation goals seek not only to replace an area equal to or greater than the lost or directly impacted area of wetlands, but also to replace the lost functions and values of the wetland areas. These functions and values are described in a guidance document[36] published by the USACE's New England District describing functions and values of wetlands and their evaluation. Impacts to wetland functions and values along the Stoughton and Whittenton Alternatives were previously analyzed (see Tables 4.16-41 and 42). The review of functions and values of impacted areas was based on an analysis of individual wetlands along the right-of-way. During the subsequent design and permitting phase, detailed wildlife habitat assessments as required by DEP regulations, would be performed, and the functions and values assessments done using the Corps methodology would be refined based on more detailed site-specific methodologies in order to refine the information on functions and values provided by wetlands along the project corridor. The USACE's guidance document on mitigation states that for effective replacement of functions, "Applicants should expect that more than 1:1 acreage replacement will usually be deemed appropriate." Replacement ratios agreed upon by MassDOT and reviewing agencies are all 1:1 or greater. Future evaluation of areas used for wetland mitigation would include an assessment of the functions and values that would be provided by these areas.

Summary

Table 4.16-52 and Table 4.16-53 provide a summary of federal wetland mitigation goals for the project for the Stoughton and Whittenton Alternatives.

[36] USACE. 1999. The Highway Methodology Workbook Supplement, Wetland Functions and Values - a Descriptive Approach. New England District, U.S. Army Corps of Engineers, NAEEP-360-1-30a. Concord, MA.

Table 4.16-52 Vegetated Wetland/Waterway Mitigation Goals (Stoughton Electric Alternative)

Watershed	Cover Type	Permanent Impact (ac)	Temporary Impact (ac)	Federal Mitigation Goal (ac)1
Buzzards Bay Watershed	OW	0.1	<0.1	0.1
	PEM	0.4	<0.1	0.7
	PSS	<0.1	0.1	<0.1
	PFO	0.8	0.7	2.8
Subtotal		1.2	0.8	3.6
Narragansett/Mt. Hope Bay Watershed	PFO	<0.1	0.1	0.1
Subtotal		<0.1	0.1	0.1
Neponset River Watershed	OW	-	<0.1	-
	PEM	-	<0.1	-
	PSS	-	<0.1	-
	PFO	<0.1	<0.1	0.1
Subtotal		<0.1	<0.1	0.1
Taunton River Watershed	OW	1.9	0.3	1.9
	PEM	0.7	0.4	1.4
	PSS	0.9	0.3	1.8
	PFO	7.6	4.1	24.8
Subtotal		11.0	4.7	29.8
Total		12.3	5.9	33.6

Notes: Cowardin Types: OW = Open Water, PEM = Palustrine Emergent, PSS = Palustrine Scrub/Shrub PFO = Palustrine Forested.
Shading denotes temporary impact amounts that will be replaced in situ.
Assumes a 2:1 mitigation ratio for marsh and scrub-scrub cover types, a 3:1 mitigation ratio for forested cover types, and a 1:1 mitigation ratio for Open Water. Also assumes an additional 0.5:1 amount of temporary impact for PFO.

Table 4.16-53 Vegetated Wetland Mitigation Goals (Whittenton Electric Alternative)

Watershed	Cover Type	Permanent Impact (ac)	Temporary Impact (ac)	Federal Mitigation Goal (ac)[1]
Buzzards Bay Watershed	OW	0.1	<0.1	0.1
	PEM	0.4	<0.1	0.7
	PSS	<0.1	0.1	<0.1
	PFO	0.8	0.7	2.8
Subtotal		1.2	0.8	3.6
Mt. Hope Bay Watershed	PFO	<0.1	0.1	0.1
Subtotal		<0.1	0.1	0.1
Neponset River Watershed	OW	-	<0.1	-
	PEM	-	<0.1	-
	PSS	-	<0.1	-
	PFO	<0.1	<0.1	0.1
Subtotal		<0.1	<0.1	0.1
Taunton River Watershed	OW	1.8	0.2	1.8
	PEM	0.2	0.3	0.5
	PSS	0.9	0.3	1.7
	PFO	7.0	3.5	22.7
Subtotal		9.9	4.2	26.7
Total		11.2	5.1	30.6

Notes: Cowardin Types: OW = Open Water, PEM = Palustrine Emergent, PSS = Palustrine Scrub/Shrub PFO = Palustrine Forested.
Shading denotes temporary impact amounts that will be replaced in situ.
Assumes a 2:1 mitigation ratio for marsh and scrub-scrub cover types, a 3:1 mitigation ratio for forested cover types, and a 1:1 mitigation ratio for Open Water. Also assumes an additional 0.5:1 amount of temporary impact for PFO.

4.16.10.3 Compensatory Mitigation Site Selection

This section describes the process undertaken by MassDOT to identify appropriate compensatory mitigation sites through a multi-level screening process. The process involved GIS analysis as well as coordination between MassDOT and regulatory agencies to review potential sites suitable for wetland establishment and preservation.

Agency Coordination and GIS Analysis

Preliminary lists were generated of potential sites to be used for wetland establishment and restoration, and potential sites to be used for land preservation. These lists were generated using sites first identified in the DEIS/DEIR, either as candidates for wetland establishment or as Priority Preservation Areas (PPAs). Most of these sites are currently undeveloped, privately owned land, although some PPAs are several hundred or more acres in size and encompass some public and private roads, buildings, and utility rights of way. A total of 25 potential wetland establishment sites and 38 PPAs were identified.

Each site was mapped using aerial photography, and GIS software was used to determine the size of each site. MassDEP wetland data layers were used to determine the cover types of adjacent or nearby wetlands. Elevation data was added to the images, as well as the extent of protected open space, priority habitat of rare species, and vernal pools within and/or adjacent to each site. This analysis was performed for each site in the list of potential wetland establishment sites as well as each site in the list of PPAs. The lists and the resulting sets of images were reviewed in meetings between MassDOT and regulatory agencies.

MassDOT met with resource agency representatives from the USACE, MassDEP, USEPA, and the Massachusetts Natural Heritage and Endangered Species Program (NHESP) to allow the reviewing agencies to have input on which sites have the highest potential value for wetland establishment and/or preservation. MassDOT reviewed each site with the agencies and noted comments. Factors deemed important by MassDOT and the reviewing agencies were:

- Proximity to the project corridor;
- Size of wetland areas adjacent to the site;
- Ability to provide compensatory flood storage; and
- Other known or potential environmental resources nearby, such as rare species habitat or protected open space.

Wetland Establishment and Restoration Sites

MassDOT and the reviewing agencies reviewed the preliminary list of potential wetland establishment sites to determine the sites with the highest potential for wetland establishment and/or restoration. Based on agency input, the preliminary list was divided into three groups:

- Tier 1 sites, which were advanced to a preliminary design stage, including preliminary grading and planting;
- Tier 2 sites, to be used in the event that not enough wetland establishment can be achieved from Tier 1 sites; and
- Sites dismissed from further consideration.

The review of the preliminary list of potential wetland establishment sites yielded 5 sites designated as Tier 1, 9 sites to be retained as Tier 2, and 11 sites that were dismissed from further consideration. Table 4.16-54 presents the preliminary list of sites reviewed by MassDOT and the reviewing agencies.

During review meetings, an additional site was added, an auto junkyard directly adjacent to Pine Swamp in Raynham, north of East Brittania Street. This site could provide a valuable wetland establishment and restoration opportunity, since at least a portion of the junkyard has been constructed on filled wetlands. In addition, the project proposes to fill approximately 0.3 acre of open water in Terry Brook Pond in Freetown. While Terry Brook Pond was not on the preliminary list of potential wetland establishment sites, MassDOT analyzed the immediate area surrounding Terry Brook Pond to identify any areas that could be used for establishment of open water areas.

Table 4.16-54 Potential Wetland Establishment Sites

Site ID	Location	Size (ac)	Adjacent Cover Type	Category	Rationale
East-01	Adjacent to cranberry bog and Little Cedar Swamp (north of Morse Rd.), Easton	1.3	Cranberry bogs	Dismiss	May have current utility as turtle nesting habitat
East-01a	Adjacent to cranberry bog and Little Cedar Swamp (north of Morse Rd.), Easton	1.0	Cranberry bogs	Dismiss	Already a wetland area, may not need restoration
East-02	Pit east of Prospect St. south of power line easement, Easton	3.1	PFO	Tier 2	
East-04	North of power line easement on Route 138, Easton	5.5	PFO	Tier 1	Upland area directly adjacent to wetland
East-05	Power line ROW between Route 138 and tracks	8.5	PFO	Dismiss	High likelihood of colonization by invasive species
Rayn-01	End of Old King Road, Raynham	3.2	PFO	Tier 2	Residential yard
Rayn-02	Access road west of Juniper Hill Drive, Raynham	8.3	PFO	Tier 2	Difficulty preventing use of area by off-road vehicles
Rayn-03	Route 138 across from dog track, Raynham	6.0	PFO, PSS	Tier 2	
Rayn-04 (Carney Yard)	Carney Yard, across ROW from dog track, Raynham	12.4	PFO	Tier 1	Both wetland and upland restoration opportunities
Rayn-05	East of ROW, between E. Brittania and Thrasher St., Raynham	2.8	PFO	Tier 2	
Taun-01	End of West Water Street, Taunton	3.2	OW	Tier 2	
Taun-02	Taunton River, Weir Junction, Taunton	7.8	OW	Dismiss	Difficulty creating emergent wetland shelves
Taun-02a	Taunton River, Weir Junction, Taunton	6.0	OW	Dismiss	Difficulty creating emergent wetland shelves
Other-01 (Middleborough Brickyard)	Corner of Middleborough, Halifax, Bridgewater	78.7	OW	Tier 2	
Other-02 (Burrage Pond WMA)	Burrage Pond between Elm Street and Route 27, Hanson and Halifax	74.4	PEM, PSS, PFO, Cranberry bogs	Tier 1	Extensive wetland restoration opportunities in cranberry bogs
BLSF-01	Beaver Brook/Bolivar Pond system, Canton	1.2	PFO	Dismiss	Existing upland appears natural and undisturbed
BLSF-02	Area of proposed frontage road, Stoughton	1.6	PFO	Dismiss	Existing upland appears natural and undisturbed
BLSF-03	Area of proposed frontage road, Stoughton	1.4	OW	Dismiss	Difficulty grading areas to match existing wetlands
BLSF-04	Black Brook/Easton golf course, Easton	1.5	PFO	Dismiss	Existing upland appears natural and undisturbed
BLSF-05	Black Brook/Easton golf course, Easton	1.5	PFO	Tier 2	
BLSF-06	Hockomock Swamp, Raynham	3.3	PFO	Dismiss	Existing upland appears natural and undisturbed

Site ID	Location	Size (ac)	Adjacent Cover Type	Category	Rationale
BLSF-07	East of Carver Street/Route 495, Raynham	1.5	PFO, PSS	Tier 1	Upland directly adjacent to wetland
BLSF-08	East of Carver Street/Route 495, Raynham	1.3	PSS	Tier 2	
BLSF-09	Pine Swamp, Raynham	3.2	PFO, PSS	Tier 1	Replaces impacted Pine Swamp flood storage
BLSF-10	Taunton River, Taunton	2.9	PFO	Dismiss	Active farmland

Cowardin Types: OW = Open Water, PEM = Palustrine Emergent, PSS = Palustrine Scrub/Shrub PFO = Palustrine Forested.
Shading denotes Tier 1 areas selected to be advanced to a conceptual design phase.

As previously discussed, the South Coast Rail project cannot fully comply with the performance standards of the WPA. While the regulations of the Act call for impacts to be mitigated onsite, not every impact along the right-of-way can practicably be mitigated for in a way that meets this criterion. Some areas of impacted BLSF cannot be replicated adjacent to the impact area due to surrounding development. Furthermore, detailed topographical information for all areas along the project corridor is not available at this level of design, and estimates of BLSF may change. Further analysis will be conducted in final design to more accurately estimate both the extent of BLSF and the effect of any impacted BLSF on the ability of the area to provide flood storage capacity.

Tier 1 Wetland Establishment Sites

Based on GIS analysis and agency review, the lists of sites were narrowed down to those sites with the highest potential value for wetland establishment or restoration. Based on input from the reviewing agencies, five sites were chosen from the preliminary list as having the highest potential for wetland establishment or restoration. Sites were renamed from their original designations (East 04, Rayn 04) to a simpler naming scheme (Site A, Site B) that will be used for the remainder of this report. The auto junkyard adjacent to Pine Swamp at East Brittania Street was also added to the list, as was Terry Brook Pond, for a total of seven sites that were advanced to a conceptual mitigation design stage. Wetland establishment and restoration opportunities are presented in Table 4.16-55 and existing conditions at each site and proposed mitigation are discussed individually.

Site A—Site A is in the Taunton River Watershed in Easton, east of Route 138 and north of the power line easement that cuts across a portion of the Hockomock Swamp. While not directly adjacent to the project right-of-way, this approximately 5.4 acre site is adjacent to a large area of forested wetland associated with the swamp. The site contains scrub-shrub areas and sparse trees, along with some unvegetated areas that appear to be the site of ATV use, based on aerial photography. The site has an elevation change of approximately 10 feet from the wetland edge to the upper limit of the site. The entire site is within rare species habitat and the Hockomock Swamp ACEC. Approximately one-third of the site is shown as existing protected open space based on a MassGIS data layer. A portion of the site also contains BLSF. This site was selected because it is an undeveloped area located adjacent to the wetland systems of the Hockomock Swamp. This site can provide over 5 acres of mitigation through wetland establishment. Although a change of grade of approximately 10 feet exists across the site, the upgradient area is also undeveloped and regrading of the topography to match the adjacent wetland landscape seems feasible.

Table 4.16-55 Tier 1 Wetland Establishment Sites

Site ID	Location	Size (ac)	Adjacent Cover Type	Watershed
A (formerly East-04)	Easton–north of power line easement on Route 138	5.4	PFO	Taunton
B (formerly Rayn-04)	Raynham–across ROW from dog track, Raynham	12.4	PFO	Taunton
C (formerly BLSF-07)	Raynham–east of Carver Street/Route 495	1.7	PFO	Taunton
D (formerly BLSF-09)	Raynham–Pine Swamp	3.5	PSS, PFO	Taunton
E	Raynham–Pine Swamp Junkyard	4.3	PSS, PFO	Taunton
F	Freetown–Terry Brook Pond	0.4	OW	Taunton
G (formerly Other-02)	Hanson–Burrage Pond WMA, between Elm Street and Route 27	61.3	PEM, PSS, PFO, Cranberry bogs	Taunton

Cowardin Types: OW = Open Water, PEM = Palustrine Emergent, PSS = Palustrine Scrub/Shrub
PFO = Palustrine Forested

Site B—Site B is in the Taunton River Watershed in Raynham, directly west of the right-of-way, opposite the Raynham dog track. The site is approximately 12.4 acres in size and consists mainly of pavement over a large oval area once used as a dog training track, along with additional paved areas to either side of the track and one building. The site is currently used for trucking and other commercial purposes, along with an access road across the right-of-way. This site is also adjacent to Wetland R62.1, a perennial stream that has formed within the right-of-way. The northern end of the site includes a steep slope of over 10 feet down to the existing wetland areas, where the old dog track was built on a large area of fill. The difference in grade between the site and the surrounding landscape decreases from the northern end of the site to the southern end, which roughly matches the surrounding landscape. The site is surrounded on three sides by rare species habitat, and to the north by forested wetlands that are part of Hockomock Swamp. The entire site is located within the Hockomock Swamp ACEC. Along much of the northern portion of the site, the existing wetlands are close to or at the edge of pavement or the toe of the fill slope. It is likely that at least a portion of this site was originally constructed on top of wetlands. This site was chosen because it represents an opportunity to restore several acres of wetland areas that are currently covered by pavement and fill. Areas at the southern end of the site would be replanted as forested upland to provide additional rare species habitat. Based on agency input and feedback, this site was viewed as being one of the best opportunities along the project corridor for wetland establishment and restoration.

Site C—Site C is in the Taunton River Watershed in Raynham, west of the project right-of-way, just south of Carver Street and Interstate 495. This 1.7 acre site is approximately 200 feet from existing residential houses and yards, and is adjacent to wetlands that would be impacted from constructing the railroad. These wetlands include both forested wetlands and scrub-shrub areas near the site. The site also contains areas of BLSF. The existing vegetation is typical forested upland, interspersed with some patches of scrub-shrub vegetation. The elevation changes approximately 10 feet from the lowest to the highest point of the site, although along the margins the elevation change is only a few feet above the mapped wetland area. The parcel is not within any rare species habitat or protected open space. This site was selected because of its proximity to both impacted wetlands and impacted BLSF along the right-of-way of the South Coast Rail project. The site has the potential to provide approximately 1.5 acres of compensatory flood storage if used for wetland establishment.

Site D—This site is similar in nature to Site C. The site is in the Taunton River Watershed in Raynham, west of the right-of-way, near the municipal border between Raynham and Taunton. The area is approximately 3.5 acres and is adjacent to wetlands of the northern part of Pine Swamp. The wetlands adjacent to Site D consist of both forested and scrub-shrub wetlands, and BLSF is also supported within this site. Four potential vernal pools lie to the north and east of the site. The existing vegetation of Site D is a mix of forested upland, interspersed with some areas of scrub-shrub upland, and is approximately 200 feet from existing residential houses and yards. The elevation of the site is fairly uniform and is approximately 3 to 6 feet above the elevation of the existing wetlands. The entire site is located within rare species habitat. No part of the site is protected open space. This site was selected because of its proximity to Pine Swamp and wetland associated with Pine Swamp. Being adjacent to existing BLSF, this site also has the potential to provide over 3.0 acres of compensatory flood storage. Wetlands established at this site would also enhance wildlife habitat for species that use the four nearby potential vernal pools.

Site E—Site E is in the Taunton River Watershed in Raynham, directly east of the right-of-way, and is adjacent to wetlands of the southern part of Pine Swamp. This site is approximately 4.3 acres. The site is currently used as an auto junkyard, and aerial photography suggests that at least part of the junkyard is built on filled wetlands. The wetlands bordering Site E consist of large contiguous areas of both forested and scrub-shrub wetlands, and the site also supports BLSF. A portion of the site falls into an area of both rare species habitat and protected open space, which is also part of the existing degraded areas. The elevation of the site is fairly uniform and the site is approximately 3 to 6 feet above the elevation of the existing wetlands in most areas, although portions of the filled area appear from aerial photography to be very close to the elevation of the existing wetlands. This site was chosen because it represents an opportunity for both wetland establishment and restoration. While a detailed study of conditions at the junkyard would have to be undertaken in a further design stage, an establishment of wetlands in this area combined with restoration of degraded areas would benefit the adjacent wetlands of Pine Swamp. The site also has the potential to provide over 3.0 acres of compensatory flood storage.

Site F—Site F is adjacent to Terry Brook Pond in Freetown, in the Taunton River Watershed. Terry Brook Pond is a large area of open water approximately 13 acres on both sides of the right-of-way. Approximately 0.3 acre of the pond would be impacted by the project. Site E is approximately 0.4 acre on the northern side of the pond and is currently comprised of forested upland bordering the pond, with a walking trail or small boat launch ramp that leads down to the pond. Site E also supports BLSF, as does much of the immediate area surrounding the pond. The elevation of the site is a few feet above the existing water elevation. No part of the site is within rare species habitat, nor is any part of the site designated as protected open space. This site was chosen because it represents an opportunity to mitigate for open water impacts that occur in the same resource area (Terry Brook Pond). The small change in elevation and amount of adjacent upland available for grading would make the design of an open water area straightforward.

Site G—Site G, the Burrage Pond Wildlife Management Area, is a large complex of former cranberry bogs in Hanson, in the Taunton River Watershed. The portion under consideration for wetland establishment encompasses several bogs totaling approximately 61.2 acres. While MassDOT has reviewed the entire area with the reviewing agencies, and has prepared a mitigation design concept for the entire 61.2 acre area, the entire area may not be necessary to achieve the mitigation goals for the project. MassDOT would commit to constructing the amount of wetland establishment or restoration necessary to achieve the goals for the project, which may encompass a smaller area than shown in the proposed mitigation design concept. MassDOT would undertake wetland establishment and restoration

at this site in conjunction with the Massachusetts Division of Wildlife (MassWildlife), which owns and administers the WMA.

The Burrage Pond Wildlife Management Area is not located along the South Coast Rail project corridor. However, its large size and proximity to other wetland resources presents opportunities for wetland establishment and restoration of the old cranberry bogs. Despite Burrage Pond not being located along the project corridor, it is a large contiguous tract of land within the Taunton River watershed and reviewing agencies indicated that this area would be a good candidate for wetland establishment and restoration, as well as long-term stewardship through management by MassWildlife. The site is adjacent to a large marsh to the northwest and west, as well as forested and scrub-shrub wetlands to the east and southeast. The topography within the bogs is very uniform, with berms several feet high separating the bogs from one another and from the large swamp to the west and the forested wetlands to the east. A small portion of the forested wetland to the east consists of Atlantic white cedar swamp. The entire site is within rare species habitat and is also protected open space. This site was chosen for its extensive opportunities for wetland establishment and restoration of the old cranberry bogs. The site has previously been studied for the purpose of establishing a wetland bank area, and as such there is good historical information on the existing topography and hydrology.

Raynham Stream Relocation—Wetland R62.1 is the perennial stream that has formed within the former railroad right-of-way in Raynham. The site was investigated for the possibility of relocating the stream to the west of the right-of-way using Natural Channel Design techniques and to assess the functions and values of the stream.

The stream is not a natural formation that was channelized to construct the original railroad. Rather, drainage ditches were constructed on either side of the original railroad berm to channel water away from the berm. The ditches have become blocked and have diverted flow onto the right-of-way of the original railroad. A culvert under the Site B access road on the east side of the right-of-way is mostly blocked, resulting in water becoming impounded on the south side of the access road. During and after rain events, water overtops the bank and flows across the access road, discharging to the west side of the right-of-way.

A preliminary concept design of a relocated stream channel was prepared and presented to the consulting agencies. Constructing this stream channel would be difficult due to excavation through several feet of bedrock that would likely be required for much of the distance, and associated increase of the cost of the project. Additionally, relocating the stream into the adjacent forested upland would create impacts to existing box turtle habitat. For these reasons, the consensus of the agencies was that resources would be better spent elsewhere on other mitigation efforts.

Preservation Areas—Based on GIS analysis and agency review of the list of PPAs, sites that provide land preservation opportunities are presented in Table 4.16-56 below. The PPAs listed in Table 4.16-56 were first identified as part of a comprehensive Corridor Plan for the South Coast Rail project to address issues of smart growth. The Corridor Plan addresses economic development and land use related to the South Coast Rail project as a whole, and "provides a framework for regional growth that is clustered, more sustainable, and better connected within the region and to metro Boston." The Corridor Plan was developed in light of expected future increases in development along the project corridor due to the economic boost the project would provide to the area. The Corridor Plan identified PPAs along the project corridor and elsewhere in the region to identify areas of land or environmental resources not currently protected, but worthy of increased levels of protection. The USACE has indicated a willingness

to allow land preservation as one of a suite of mitigation options, to accompany the wetland establishment and restoration discussed in the previous section.

Table 4.16-56 Potential Land Preservation Opportunities

PPA #	Site Name	Municipality	Size (ac)	Has Priority Habitat	Has Vernal Pools	Category	Comments
P09	Gobi Property	Foxborough, Sharon	191	N	Y	Tier 2	
P14	Municipal Water Source and Future Well Site	Foxborough	77	PH 488/EH 392	Y	Tier 2

P69	Nasketucket Bay State Reservation Area	Mattapoisett, Fairhaven	185	PH 15/EH 79	N	Tier 2	

Shading denotes Tier 1 areas.

1 ”Original delineated parcel” refers to parcels as shown on the Corridor Plan map.

The number of sites and total area in Table 4.16-56 is much larger than any potential area needed for preservation. At the current level of design for the project, the amount of land potentially needed for preservation is not known. Preservation would be used if the area of federal wetland mitigation needed would not be fully achieved by wetland establishment and restoration. The sites listed in Table 4.16-56 provide a broad range of possible sites to ensure that opportunities for preservation can be developed once exact amounts of preservation acreage needed are known.

The preliminary list was reviewed by MassDOT and the reviewing agencies to determine the sites most likely to provide preservation opportunities for both wetlands and developable uplands. Factors deemed important for a site to provide good preservation opportunities were:

- Proximity of the site to the project corridor, particularly in municipalities or communities that would experience wetland or other environmental impacts;
- Proximity to the Hockomock Swamp, which was given priority by the reviewing agencies;

- Diversity of wetland and upland cover types at the site;
- Amount of undeveloped upland at the site, particularly if the undeveloped upland could feasibly be developed in the future; and
- Other known or potential environmental resources at the site, such as rare species habitat or clusters of certified or potential vernal pools.

Based on agency input, the PPAs were divided into two groups, Tier 1 and Tier 2. Tier 1 sites have a higher potential to provide preservation opportunities. Tier 2 sites would be considered only if not enough wetland preservation can be achieved from Tier 1 sites.

Appendix 4.16-D includes graphics showing each of these areas, along with their size and any adjacent wetlands, rare species habitat, and other environmental factors.

Summary

Sites have been chosen that based on review of available information, along with input from review agencies. The sites described in this chapter represent Tier 1 sites that have a high likelihood of being able to replace wetlands impacted by the South Coast Rail project. However, should one or more of these sites prove to be not practicable for wetland establishment or preservation and additional area is needed, Tier 2 sites can be examined. Based on the review of available information and agency input, the sites presented in this report for wetland establishment, restoration, enhancement and preservation are all located in the Taunton River Watershed. While other watersheds through which the project passes are affected, The Taunton River Watershed comprises 88 percent of the wetland impact along the right-of-way for the Stoughton Electric Alternative and 86 percent for the Whittenton Alternative. Although Tier 1 sites for wetland establishment were not identified in other watersheds at this design stage, potential areas for preservation have been identified in all project watersheds.

The MassDEP wetland mitigation guidance document calls for wildlife habitat evaluations of wetland areas impacted by a project, in order to facilitate the replication of the wildlife functions provided by the area. Detailed wildlife habitat evaluations of impacted areas of the South Coast Rail project would be undertaken during the final design phase of the project. This may require adjustments to the amount or type of wetlands to be replicated in order to provide adequate mitigation for impacted wildlife habitat and other functions and values.

There are watershed action plans outlining overall goals within Buzzards Bay, Mount Hope Bay, Neponset River, and Taunton River Watersheds. Mitigation efforts would be coordinated with the different associations and follow their action plans to the extent possible. The Buzzards Bay Comprehensive Conservation and Management Plan[37] (originally created in 1991 and currently being revised), Mount Hope and Narragansett Bay Five-Year Action Plan[38], Neponset River Watershed Action Plan (part of the Boston Harbor Watersheds 2004 2009 Action Plan[39]) and the Five-Year Watershed

[37] Buzzards Bay Project. Buzzards Bay Comprehensive Conservation and Management Plan, August 1991

[38] Massachusetts Executive Office of Environmental Affairs. Mount Hope and Narragansett Bay Five-Year Action Plan. November 2004.

[39] Massachusetts Executive Office of Environmental Affairs. Boston Harbor Watersheds 2004 - 2009 Action Plan, November 2004.

Action Plan for the Taunton River[40] would be consulted when creating final mitigation goals and selecting mitigation locations. Several of the plans are being revised or updated to accurately reflect current conditions within the watershed. The most recent plan available for each impacted watershed would be used to guide mitigation efforts once the preferred alternative is selected.

4.16.10.4 Proposed Compensatory Mitigation

Based on input from reviewing agencies and GIS analyses, the initial list of 25 potential wetland establishment sites was narrowed down to five sites. An additional two sites raised in discussions with the reviewing agencies (the auto junkyard adjacent to Pine Swamp and Terry Brook Pond) were also added to the final list, for a total of seven final sites to be advanced to a conceptual mitigation design. This chapter describes the proposed wetland compensatory mitigation package. Figures are provided showing the existing conditions at each parcel, along with a proposed design concept.

Methodology

The following sections describe the methodology used for the conceptual mitigation designs in each proposed wetland establishment site.

Overall Design and Elevation

Conceptual mitigation design began with a detailed analysis of the Tier 1 establishment and restoration sites using GIS software. Based on input from the reviewing agencies, Light Detection and Ranging (LiDAR) elevation data was added to the analysis of the sites. The LiDAR dataset is a fairly recent (released in July 2012) dataset produced by Massachusetts Office of Geographic Information (MassGIS). LiDAR data, while not as accurate as a ground survey of topography, produces finer-scale topographical information than the existing state elevation data layers, which show elevation only in 3 meter (10 foot) increments. After processing the LiDAR data, elevation contours at the wetland establishment sites were generated at 1 meter (3.3 foot) intervals.

The use of LiDAR data enabled more detailed analysis of elevation at these sites, and allowed for more detailed mitigation design concepts that incorporated proposed grades into the design. Proposed grades were included in the concept design for each wetland establishment area, to determine if grading was practicable at the site and if the elevation of the existing wetland areas could be matched in the adjacent wetland establishment area, with enough surrounding space to regrade the upland buffer to match existing grades.

Vegetation Types and Mitigation Goals

The general vegetation types used in the design concept for each wetland establishment site were based on the Cowardin classification of the natural vegetation of the wetlands adjacent to each site. Generally, the design concepts propose equivalent vegetation types adjacent to existing vegetation types, such as palustrine forested wetland adjacent to existing palustrine forested wetlands and scrub shrub wetlands adjacent to existing scrub-shrub wetlands. Using this design framework is more likely to result in the successful establishment of the target plant communities. The minimum mitigation ratios

[40] Massachusetts Executive Office of Environmental Affairs. Five-Year Watershed Action Plan for the Taunton River Watershed, September 2006

given in the USACE's Compensatory Mitigation Guidance were the basis for the total mitigation acreage goals for each vegetation type. These minimum mitigation ratios and total acreage goals were considered when creating the mitigation concept designs for each site. The sum of the proposed acreage of each vegetation type at all sites seeks to meet or exceed the previously stated mitigation goals. This allows for adjustments to the total mitigation goals that may be necessary in final design. The sum of each vegetation type also meets or exceeds the mitigation goals laid out in the MassDEP's Inland Wetland Replication Guidelines. The guidelines include a requirement that at least 75 percent of the surface of the replacement area be established with indigenous wetland plant species within two growing seasons.

Planting Plans

Planting plans were developed based on each vegetation type proposed for establishment at each site. Recommended plant lists are included for palustrine forested, palustrine scrub-shrub, and palustrine emergent wetland areas. These plant lists are general recommendations, and species may change in final design. Plant lists were generated using species native to Massachusetts and New England, and do not use invasive species, such as those listed on the Massachusetts Prohibited Plant List[41]. Plant lists for palustrine forested wetlands (Table 4.16-57) palustrine scrub-shrub wetlands (Table 4.16-58) and palustrine emergent wetlands (Table 4.16-59) are designed to create a representative plant community based on the surrounding or adjacent vegetation. In addition, certain areas such as the Burrage Pond site may lend themselves to restoration of Atlantic white cedar habitat; although the regulated activities noted above are not expected to measurably affect existing Atlantic white cedar swamps, USACE intends to encourage this and other opportunities to restore this increasingly rare habitat type.

Table 4.16-57 CONCEPTUAL Planting Specifications, Palustrine Forested Wetlands

Common Name	Latin Name	Wetland Indicator Status	Spacing
Red maple	*Acer rubrum*	FAC	20 ft. oc[1]

oc = on center

Soils

Soils used for wetland establishment sites would either be translocated (i.e., existing wetland soils from impacted wetland areas would be reused) or created with soil amendments. While translocation is the preferred method stated in the MassDEP mitigation guidance, created wetland soils may also be used. Generally, wetland soils are created from a 1:1 mixture (or equal volumes) of organic and mineral materials, with the final product containing at least 12 percent organic carbon by weight. According to USACE's guidance, soils to be used for emergent wetlands in permanently or semi permanently flooded areas should have a target organic carbon level of 4 to 6 percent. Soil specifications would be generated for each wetland establishment site to include a description of the composition of the existing soil, added material, and the techniques used in its preparation. A detailed schedule would be developed for

the collection and stockpiling of soils. No soil used for creation of wetland soils would be taken from any area supporting invasive species.

Wildlife Habitat Features

In addition to wetland plantings and establishment of appropriate wetland hydrology within each wetland establishment site, wildlife habitat features would be used wherever feasible. The creation of hummock and hollow microtopography where appropriate creates burrowing opportunities. Any large rocks or boulders uncovered during excavation would be left in place or set aside to be reused. These can provide nesting, burrowing, and hiding places. Fallen logs and woody debris provide important cover and foraging habitat to a variety of wildlife species. Logs and woody debris in varying stages of decay can be used to provide habitat features. Upland tree species close to the wetland boundary may not be affected by excavation, but are likely to suffer mortality in the increased hydrologic regime of the newly established wetland. These trees can be left to stand in place, and when they die they will provide snags for perching, foraging, and nesting opportunities for a variety of bird species including woodpeckers. Alternatively, whole trees can be pushed over into the newly established wetland to provide wildlife habitat features.

Construction Guidelines

Construction of the wetland establishment sites would seek to minimize erosion and sedimentation into existing wetlands, and to maximize the establishment and survival of plantings. Final mitigation plans would be developed for each wetland establishment site based on a detailed updated topographic survey, groundwater monitoring, test borings, and soil sampling. The replacement wetlands would be designed to conform to the guidelines developed by the USACE and MassDEP guidance and to meet the performance standards in the WPA regulations.

The construction of the wetland establishment sites would involve excavation of the non-wetland areas adjacent to the existing wetlands. The excavation would bring the elevation of the non-wetland areas down to the grade of the existing wetlands or lower, depending on the type of vegetational community desired. The excavation would bring the replacement areas into contact with groundwater, which establishes a hydrologic connection to a water source of sufficient volume and duration to maintain wetland hydrology. This in turn supports wetland vegetation and the development of hydric soils. Each site would be graded with microtopography to mimic the surface of the wetlands that will be impacted.

Each wetland establishment site would be vegetated (planted) with native wetland species in accordance with USACE and MassDEP guidance, and in accordance with the previous plant lists. In final design, dominant native wetland plant species observed in the existing wetlands adjacent to a wetland establishment site may be substituted for plants in the previous plant lists.

Construction Oversight

The construction of successful replacement wetland sites would require oversight by a supervising wetland scientist who is an experienced field professional. The supervising wetland scientist may need to make field adjustments in grading and/or planting in response to field conditions at each wetland establishment site. These modifications can ensure that hydrologic conditions necessary to support wetland vegetation and functions are created. During construction, the supervising wetland scientist may relocate up to 50 percent of the plantings if conditions require.

Construction Sequence

A general sequence of construction events follows.

- Before construction begins, an erosion control barrier would be erected around the entire proposed wetland replacement site, except the upgradient edge to allow machinery access to the site. The erosion control barrier prevents erosion of disturbed soils and sedimentation into the adjacent existing wetland areas.

- The wetland establishment site would be cleared and grubbed, and would be excavated to a depth of 12 inches below the final design elevation. In response to subsurface hydrologic conditions, the supervising wetland scientist may make minor modifications to the rough grading plan in the field. The supervising wetland scientist would inspect the sub-grade of the wetland establishment site to ensure that wetland hydrology has been established.

- The wetland establishment site would then be backfilled with wetland soils that have either been translocated or created. Hydric soils that are created would follow the guidelines discussed above. Once the final topsoil is in place, it would be graded to achieve a topography to match the existing adjacent wetland, or to achieve topography of the target wetland cover type. Often, a slight hummock/hollow microtopography simulates a natural substrate. Additionally, low spots would be created within the wetland establishment site to provide temporary ponding of surface waters.

- Rocks and boulders uncovered during the excavation may be left in place, provided they do not result in a large decrease in the plantable area of the wetland establishment site. If possible, rocks and boulders would be repositioned to provide crevices and cavities suitable for wildlife use.

- Fallen logs and other woody debris would be distributed in the wetland establishment site to provide beneficial habitat features for wildlife. Woody material would be distributed to cover approximately 2 percent of the site's surface area. Logs and woody debris would be of various sizes and in various degrees of decomposition.

- After work with heavy machinery is completed, an erosion control barrier would be erected along the upgradient edge of the wetland establishment site.

- Plantings would take place according to the planting schedule of the final design of each wetland establishment site, which would specify species, size, and quantity of plantings. Prior to delivery to the site, the supervising wetland scientist would visit the nursery or nurseries providing the planting stock to ensure that the specimens are healthy, free from pests and any invasive plant material, and suitable for use within the wetland establishment site. Unsuitable specimens would be rejected and replaced with suitable specimens. The supervising wetland scientist must approve any planting substitutions. All woody plant stock would be either bare root stock or container grown. Planting within the wetland establishment site and adjacent uplands would conform to the plans or would be completed in accordance with directions provided in the field. Only plant materials native and indigenous to the region would be used. Use of cultivars would be prohibited. Species not specified in the final planting plan would not be used without written approval from the permitting agency.

- All plantings would be spaced in similar species clusters in a random distribution, at the direction of the supervising wetland scientist, to simulate natural growth patterns.

- Upon completion of planting, the areas around each plant or cluster or plants would be mulched with a 2 inch thick layer of leaf litter or other natural organic material (not fresh wood chips)

- The erosion control barriers would be disassembled and properly disposed of before November 1 of the third full growing season after planting of the wetland establishment site. Sediment collected by the barriers would be removed and disposed of in a manner that prevents erosion and transport to a wetland or waterway. If minor grading is required in the immediate zone around the erosion control barrier to provide surface hydrologic connection between the wetland establishment site and the existing wetland area, it would be done by hand and stabilized by mulch.

- The wetland establishment site would be inspected twice a year, during the spring and fall, each year of the post construction monitoring period for invasive or unwanted plants. If invasive species are found, they would be uprooted and removed from the area, and/or treated with a glyphosate herbicide approved for wetland use and applied by hand. Invasive plants are discussed in more detail below.

- Long-term monitoring of the wetland establishment site would be conducted as recommended below.

Invasive Species Control Plan

Exotic or invasive species commonly observed in the surrounding landscape may colonize wetland establishment sites as the vegetation community develops. These species potentially include:

- *Alliaria petiolata*, garlic mustard

- *Berberis thunbergii*, Japanese barberry

- *Lonicera* spp., shrub honeysuckle

- *Lysimachia nummularia*, moneywort

- *Lythrum salicaria*, purple loosestrife

- *Phalaris arundinacea*, reed canary grass

- *Phragmites australis*, common reed

- *Frangula alnus*, glossy buckthorn

- *Rosa multiflora*, multiflora rose

- *Solanum dulcamara*, bittersweet nightshade

To protect the functions and integrity of wetland replacement sites, each site would be inspected twice a year as part of the long term monitoring plan for the site. If feasible, any exotic or invasive plants would be pulled by hand and removed from the wetland replacement site. In the event that herbaceous species become established and hand removal is not feasible, a qualified pesticide applicator would be contacted to spray plants with an appropriate herbicide. Spraying would be done using a backpack unit and dye mixed with the liquid herbicide to minimize overspray and damage to native wetland species.

Post Construction Monitoring

This section provides a monitoring and assessment plan for the wetland establishment sites. A 10 year monitoring period is proposed.

Field Monitoring and Report Schedules

Monitoring reports would be prepared, based on field observations, in the format required by the USACE New England District Mitigation Guidance[42]. Monitoring of field conditions would be performed for each of the first three full growing seasons following construction of the wetland establishment sites. Observations would occur at least two times during the growing season (in late spring/early summer and again in late summer/early fall). Each annual monitoring report would be submitted to the USACE and MassDEP no later than December 15 of the year being monitored. Failure to perform the monitoring and submit a monitoring report would constitute permit non-compliance. A self-certification form would be completed, and signed as the transmittal coversheet for each annual monitoring report and would indicate the permit number and the report number. The reports would address success standards in the summary data section and would address any additional items noted in the monitoring report requirements. The reports would also include the monitoring report appendices listed below. The first year of monitoring would be the first year that the wetland establishment sites have been through a full growing season after completion of construction and planting. For the purpose of this monitoring effort, a growing season starts no later than May 31. If there are problems that need to be addressed and if the measures to correct them require prior approval from the agencies, MassDOT would contact the agencies as soon as the need for corrective action is discovered.

Remedial measures would be implemented at least one year prior to the completion of the 10-year field monitoring period, to attain the success standards within three growing seasons after completion of construction of the wetland establishment sites. Should measures be required within one year of the end of the 10-year field monitoring period, the monitoring period would be extended as necessary to demonstrate success of the mitigation site after the remedial work is completed. Measures requiring earth movement for changes in hydrology would not be implemented without written approval from the USACE and MassDEP.

At least one reference site adjacent to or near each wetland establishment site would be described and shown on a locus map.

[42] U.S. Army Corps Of Engineers New England District Regulatory Division. 2010. New England District Compensatory Mitigation Guidance. Concord MA.

Field Monitoring Methods

Vegetation, soils, and hydrology development would be monitored within the wetland establishment site and at a reference site established in the adjacent wetland. The following data would be collected in the wetland establishment site and the reference site during each site visit:

- Two monitoring wells would be installed in the wetland establishment site and the reference site, and shown on a plan;
- Two sediment horizon markers would be established in the wetland establishment site and the reference site to characterize sediment accumulation;
- Water table height would be measured two times per year, during site visits;
- Sediment accumulation;
- Percent vegetative cover;
- Species composition, with reference to wetland indicator status;
- Height and stem density for dominant target species and invasive species; and
- Evidence of wildlife use of the area (tracks, scat, dens, nests, or evidence of browsing.

Success Standards

Each monitoring report would answer the following questions (success standards):

- Does the wetland establishment site have the hydrology, as demonstrated by observations of monitoring well levels, to support the designed wetland type?
- Is the proposed hydrology met at the site?
- What percentage of the site is meeting project hydrology levels? Areas that are too wet or too dry should be identified along with suggested corrective measures.
- Does the wetland establishment site have at least 80 percent aerial cover of non-invasive hydrophytes, excluding planned open water areas or planned bare soil areas?
- Are invasive species being controlled so that the aerial cover of invasives is less than 5 percent?
- Does data from the substrate cores and horizon markers show increasing organic carbon content and sediment accumulation over time?
- Are all slopes, soils, substrates and constructed features within and adjacent to the wetland establishment area stabilized?

Monitoring Report Requirements

Each monitoring report would address the following items:

- Dates that work began and ended.
- Description of monitoring inspections since the last report.
- Soils and hydrology data.
- Remedial actions undertaken to meet success standards.
- Status of erosion control measures.
- Visual estimates of total percent cover, and visual estimate of percent cover of invasive species.
- General health and vigor of each of the plant species in the wetland establishment sites, with diagnosis of cause(s) of morbidity or mortality.
- Evidence of wildlife use.
- Remedial measures recommended to achieve or maintain success, and improve the extent to which the wetland establishment site replaces the lost functions and values.
- Each monitoring report would include four appendices:
- A copy of the permit, with mitigation special conditions and mitigation goals.
- An as-built planting plan showing the location and extent of the designed plant community type. (This is required only in the first monitoring report.)
- A species list of volunteer plant species in each community type.
- Representative photos of each mitigation site, taken from the same location for each monitoring event.

Final Assessment

A final post-construction assessment of the condition of the wetland establishment site would be performed at the end of the 10 year monitoring period. The assessment report would be submitted to the USACE and MassDEP by December 15 of the year the assessment is conducted. This assessment would:

- Summarize the original or modified mitigation goals and discuss the level of attainment of these goals.
- Describe significant problems and solutions during construction and post-construction.

- Identify agency procedures or policies that encumbered implementation of the mitigation plan. The assessment will specifically note procedures or policies that contributed to lower success or effectiveness than anticipated.

- Recommend measures to improve efficiency, reduce cost, or improve effectiveness of similar projects.

- The assessment will include the following appendices:

- Summary of the functions and values assessment of the wetland establishment areas.

- Calculation of the area of wetlands in each site, accompanied by a scaled drawing showing the wetland boundary and representative transects, with data sheets supporting the delineation.

- Comparison of the area and extent of delineated constructed wetlands with the area and extent of created wetlands proposed in the mitigation plan.

- Photos of the wetland establishment site taken from the same locations as the monitoring photos.

Tier 1 Wetland Establishment Sites

Five sites were selected as Tier 1 wetland establishment sites. The auto junkyard adjacent to Pine Swamp at East Brittania Street and Terry Brook Pond were also added to the list, for a total of seven sites that were advanced to a conceptual mitigation design stage. Six of the sites are located along the project corridor, or in the case of Site A, adjacent to the same wetland complex (the Hockomock Swamp) as the project corridor. The seventh site is Burrage Pond in Hanson, which is not located along the project corridor but that provides extensive wetland establishment and restoration opportunities. The following sections describe the proposed wetland concept design for each wetland establishment site.

Site A—Site A is approximately 5.4 acres, and the entire site is adjacent to existing forested wetland, at an elevation of approximately 71 feet. Figure 4.16-6 shows the existing conditions at Site A. Forested wetland is proposed for this site, since it is the vegetation type that would have the highest likelihood of long term success at this site and would expand the existing forested wetland. Wetland establishment at this site would create approximately 5.4 acres of new forested wetland, by excavating down to the existing wetland elevation of 71 feet to establish wetland hydrology. Wetlands created here would also provide approximately 4.9 acres of compensatory flood storage by expanding the existing floodplain over the created wetland.

Functions and values provided by the newly established wetland would include groundwater recharge/discharge, floodflow alteration, sediment/toxicant/pathogen retention, nutrient removal/retention/transformation, production export, wildlife habitat, and threatened or endangered species habitat. The area outside the wetland replacement site would be graded to match the existing topography Approximately 2.4 acres of additional upland would be required for grading, resulting in 7.8 acres of land acquisition needed to construct this wetland establishment site. Figure 4.16-7 shows the proposed wetland establishment design concept plan for this Site A.

Site B—Site B is approximately 12.4 acres. This site is partially built on fill material, particularly at the northern end of the old dog track (now paved) that makes up the central portion of this site. While the elevation of the northern portion of the site is currently 15 feet or more above the elevation of the existing wetlands, the hydrology of the surrounding area suggests that wetland restoration is possible at approximately half of the site through removal of fill material that was likely placed on top of wetlands. Figure 4.16-8 shows the existing conditions at Site B.

The existing pavement and enough fill material would be removed to match the elevation of Site B with the elevation of the existing wetlands to the north and west (approximately elevation 91 feet). Additionally, a channel would be rebuilt along the west side of the right-of-way to contain the perennial stream in Wetland R 62.1. The stream would flow into the wetlands adjacent to Site B, partially restoring the hydrology to this area and increasing the likelihood of long term successful hydrology at Site B. Wetland reestablishment at this site would result in approximately 6.5 acres of restored wetland area. As with Site A, the surrounding wetlands are entirely forested, so the proposed wetland reestablishment would produce additional forested wetlands here, and would restore the functions of the wetlands originally filled to construct the dog track. Although Hockomock Swamp to the north contains Atlantic white cedar, the wetlands surrounding Site B do not, and the hydrology of the area does not support this species.

Functions and values provided by the newly reestablished wetland would include groundwater recharge/discharge, floodflow alteration, sediment/toxicant/pathogen retention, nutrient removal/retention/transformation, production export, wildlife habitat, and threatened or endangered species habitat. The southern half of the site would be cleared of existing pavement and would be planted as upland forest, resulting in approximately 5.9 acres of restored upland. This area would provide additional wildlife habitat as well as rare species habitat. Figure 4.16-9 shows the proposed wetland establishment design concept for Site B.

Site C—Site C is approximately 1.7 acres and is surrounded on three sides by forested and scrub-shrub wetlands that begin at an elevation of approximately 81 feet. This site also provides flood storage as BLSF, at an elevation of approximately 81 feet. Figure 4.16-10 shows the existing conditions at Site C.

Wetland establishment would result in approximately 1.2 acres of forested wetland and 0.5 acre of scrub-shrub wetland, by excavating down to the wetland elevation of 81 feet to establish wetland hydrology. Wetlands created here would also provide approximately 1.5 acres of compensatory flood storage by expanding the existing floodplain over the created wetland.

Functions and values provided by the newly established wetland would include groundwater recharge/discharge, floodflow alteration, sediment/toxicant/pathogen retention, nutrient removal/retention/transformation, production export, and wildlife habitat. The area outside the wetland replacement site would be graded to match the existing topography. Approximately 0.4 acre of additional upland would be required for grading, resulting in 2.1 acres of land acquisition required to construct this wetland establishment site. Figure 4.16-11 shows the proposed wetland establishment design concept for Site C.

Site D—Site D is approximately 3.5 acres and is adjacent to forested and scrub-shrub wetlands that begin at an elevation of approximately 62 feet. This site also provides flood storage as BLSF at an elevation of approximately 60 feet. Figure 4.16-12 shows the existing conditions at Site D.

Wetland establishment at Site D would seek to create three different wetland cover types. The presence of potential vernal pools near the eastern edge of the site provides evidence of hydrology that could support an area of palustrine emergent wetlands by excavating down to an elevation of approximately 59 feet. This would provide approximately 1.1 acres of emergent wetland. Grading to an elevation of approximately 61 feet would create approximately 1.2 acres of scrub-shrub wetland in the middle third of the site. Finally, grading to an elevation of approximately 62 feet would create approximately 1.2 acres of forested wetland. Wetlands created at Site D would also create approximately 3.1 acres of compensatory flood storage by expanding the existing floodplain over the created wetland.

Functions and values provided by the newly established wetland would include groundwater recharge/discharge, floodflow alteration, sediment/toxicant/pathogen retention, nutrient removal/retention/transformation, production export, wildlife habitat, and threatened or endangered species habitat. Minimal grading would be needed to match the created wetland with the existing upland. Figure 4.16-13 shows the proposed wetland establishment design concept for Site D.

Site E—Site E is the automotive junkyard and is approximately 4.3 acres, adjacent to forested and scrub-shrub wetlands that begin at approximately elevation 59 feet. This site also provides flood storage as BLSF at approximately elevation 60 feet. Figure 4.16-14 shows the existing conditions at Site E.

Wetland establishment would result in approximately 2.2 acres of forested wetland and 2.1 acres of scrub-shrub wetland at Site E, by excavating to elevation 59 feet to establish wetland hydrology. Wetlands created here would also provide approximately 3.2 acres of compensatory flood storage by expanding the existing floodplain over the created wetland. Wetland restoration would also be constructed in current BLSF and within upland areas on the site degraded by the auto junkyard. From aerial photography, portions of the site appear to be filled wetlands.

Functions and values provided by the newly established wetland would include groundwater recharge/discharge, floodflow alteration, sediment/toxicant/pathogen retention, nutrient removal/retention/transformation, production export, wildlife habitat, and threatened or endangered species habitat. Minimal grading would be needed to match the created wetland with the existing upland. Figure 4.16-15 shows the proposed wetland establishment design concept for Site E.

Site F—Site F is approximately 0.4 acre and is adjacent to Terry Brook Pond, which has a shoreline elevation of approximately 55 feet. This site provides flood storage as BLSF at an elevation of approximately 56 feet. Figure 4.16-16 shows the existing conditions at Site F.

Wetland establishment would result in approximately 0.4 acre of open water at Site F by excavating below the wetland elevation of 55 feet to establish wetland hydrology. Establishment of open water at this site would compensate directly for the South Coast Rail project impacts to Terry Brook Pond. Wetlands created here would also create approximately 0.4 acre of compensatory flood storage area, by expanding the existing BLSF.

Functions and values provided by the newly established wetland would include groundwater recharge/discharge, floodflow alteration, fish and shellfish habitat, sediment/toxicant/pathogen retention, nutrient removal/retention/transformation, production export, sediment/shoreline stabilization, wildlife habitat, recreation, and visual quality/aesthetics. The area outside the wetland replacement site would be graded to match the existing topography. Minimal grading would be needed to match the created wetland with the existing upland. Figure 4.16-17 shows the proposed wetland establishment design concept for Site F.

Site G—Site G (the Burrage Pond WMA) represents the largest wetland establishment site at 61.3 acres. As discussed previously, Site G is not along the project corridor, but would provide opportunity for extensive wetland establishment and restoration where there are now abandoned cranberry bogs. While MassDOT has evaluated the entire area with the reviewing agencies and has prepared a mitigation design concept for the entire 61.2 acre site, the entire site may not be necessary to achieve the mitigation goals for the project. MassDOT would commit to constructing the amount of wetland establishment necessary to achieve the goals for the project, which may encompass a smaller area than shown in the proposed mitigation design concept. MassDOT would undertake wetland establishment and restoration at this site in conjunction with MassWildlife, who owns and manages the WMA.

The site was previously the focus of study for a potential wetland banking pilot program, and as such there is historical information on the size and extent of the site as well as a previous wetland mitigation design concept. The previous design concept focused on three areas of the site (Areas A, B, and C). Two of these, Areas A and C are part of Site G; Area B is not part of Site G and will not be discussed further. In addition to Areas A and C, three additional locations of the site (referred to as Areas D, E, and F) have been studied by MassDOT for this potential wetland establishment site. Table 4.16-60 lists the different areas of Site G and their size in acres. All five areas are abandoned cranberry bogs enclosed by earthen berms. Figure 4.16-18 shows the existing conditions at Site G.

Table 4.16-60 Site G Areas

Area	Description	Size (acre)	Current Elevation (feet)
A	Single large bog	15.0	65
C	Single large bog	27.3	59
D	Two small bogs separated by berm	10.7	62
E	Two small bogs separated by berm	6.6	62
F	Single small bog	1.7	59/62

Mitigation at Site G would consist of wetland establishment and restoration. The entire area is already classified as wetland cranberry bogs, with the exception of the berms surrounding the bogs. Wetland establishment and creation at this site would create a diversity of wetland cover types. The following sections detail the wetland establishment proposed for each area. Figure 4.16-19 shows the proposed wetland establishment design concept for Site G.

Area A is a single large bog of approximately 15.0 acres and has the highest elevation of any portion of Site G at approximately 65 feet. Forested wetland is proposed for this location. Wetland establishment would create approximately 15.0 acres of forested wetland at Area A. Existing berms around the perimeter of Area A would be retained. Functions and values provided by the newly established wetland would include groundwater recharge/discharge, floodflow alteration, sediment/toxicant/pathogen retention, nutrient removal/retention/transformation, production export, wildlife habitat, educational/scientific value, and threatened and endangered species habitat.

Area C is a single large bog that is approximately 27.3 acres and has the lowest elevation at Site G of approximately 59 feet. Forested wetland is proposed for this area, with a focus on providing habitat for Atlantic white cedar. Atlantic white cedar swamps are considered imperiled in Massachusetts by the NHESP. Standing water in these habitats generally occurs for half the year or longer. Wetland

establishment would create approximately 27.3 acres of forested wetland within Area C. Further study would be required to determine the acreage that could feasibly be devoted to Atlantic white cedar. The existing berms on the east and south sides of Area C would be removed to connect this area to the adjacent wetland community. The existing berms on the north and west sides of Area C would be left in place. Functions and values provided by the newly established wetland would include groundwater recharge/discharge, floodflow alteration, sediment/toxicant/pathogen retention, nutrient removal/retention/transformation, production export, wildlife habitat, uniqueness/heritage, educational/scientific value, and threatened and endangered species habitat.

Area D consists of two smaller bogs separated by a berm, totaling 10.7 acres, at an elevation of approximately 62 feet. Wetland establishment would create approximately 10.7 acres of scrub-shrub wetland at Area D. The existing berm separating the two bogs would be removed. Other existing berms around the perimeter of Area D would be left in place. Functions and values provided by the newly established wetland would include groundwater recharge/discharge, floodflow alteration, sediment/toxicant/pathogen retention, nutrient removal/retention/transformation, production export, wildlife habitat, educational/scientific value, and threatened and endangered species habitat.

Area E consists of two smaller bogs separated by a berm, totaling 6.6 acres, at an elevation of approximately 62 feet. Excavation of the area would allow creation of approximately 6.6 acres of open water wetland. The existing berm separating the two bogs would be removed as part of the site excavation. Other existing berms around the perimeter would be left in place. Functions and values provided by the newly established wetland would include groundwater recharge/discharge, floodflow alteration, fish and shellfish habitat, sediment/toxicant/pathogen retention, nutrient removal/retention/transformation, production export, wildlife habitat, recreation, educational/scientific value, visual quality/aesthetics, and threatened and endangered species habitat.

Area F consists of a single small bog, 1.7 acres, at an elevation of between 59 and 62 feet. Emergent marsh wetland is proposed for this area. Wetland establishment would result in approximately 1.7 acres of emergent marsh wetland at Area F. Existing perimeter berms would be left in place. Functions and values provided by the newly established wetland would include groundwater recharge/discharge, floodflow alteration, sediment/toxicant/pathogen retention, nutrient removal/retention/transformation, production export, wildlife habitat, educational/scientific value, visual quality/aesthetics, and threatened and endangered species habitat.

Summary of Proposed Mitigation

Wetland mitigation for the South Coast Rail project is proposed to use wetland establishment, reestablishment, enhancement and preservation. Mitigation goals were established following both MassDEP regulations and guidance and USACE mitigation rules (33 CFR 332) and guidance. The mitigation goals established for state resource areas were:

- A 1:1 replacement ratio for BLSF and LUW; and
- A 2:1 replacement ratio for BVW.

The mitigation goals established for federal resource areas were:

- A 1:1 replacement ratio for permanent impacts to Open Water wetlands;

- A 2:1 replacement ratio for permanent impacts palustrine emergent and scrub-shrub wetlands;
- A 3:1 replacement ratio for permanent impacts to palustrine forested wetlands;
- A 1:1 replacement ratio for temporary impacts to palustrine emergent and scrub-shrub wetlands, to be replaced in situ; and
- A 1.5:1 replacement ratio for temporary impacts to palustrine forested wetlands, to be replaced in situ plus additional mitigation added to the mitigation goals for the loss of forested wetland cover associated with the delay in the growth of tree species.

MassDOT met with reviewing agencies of the ICG to review lists of potential sites for both wetland compensation and land preservation. Based on agency input and GIS analysis, the list of potential sites for wetland establishment was narrowed down to five sites, plus an additional two sites raised by agency members, for a total of seven sites that were advanced to a wetland compensation design concept. Wetland establishment at these sites is proposed to meet federal and state mitigation goals by providing:

- Up to 76.1 potential acres of BVW mitigation (mitigation required is 19.2 acres for the Stoughton Alternative or 16.8 acres for the Whittenton Alternative);
- Up to 7.0 potential acres of LUW mitigation (required area is 1.9 acres for permanent impacts on the Stoughton Alternative or 1.8 acres for the Whittenton Alternative); and
- Up to 13.1 potential acres of BLSF mitigation (mitigation required is 6.7 acres for the Stoughton Alternative or 4.7 acres for the Whittenton Alternative). Final design of BLSF mitigation will also assess the volume of compensatory storage provided on a foot by foot basis in comparison to the impacted BLSF.
- Wetland establishment at these sites is proposed to meet federal mitigation goals by providing:
- Up to 58.8 potential acres of palustrine forested wetlands mitigation (required area is 25.5 acres for permanent impacts on the Stoughton Alternative or 23.6 acres for the Whittenton Alternative);
- Up to 14.5 potential acres of palustrine scrub-shrub wetlands (required area is 1.8 acres for both alternatives);
- Up to 2.8 potential acres of palustrine emergent wetlands mitigation (required area is 1.8 acres for permanent impacts on either the Stoughton or Whittenton Alternatives); and
- Up to 7.0 potential acres of Open Water mitigation (required area is 1.9 acres for permanent impacts on the Stoughton Alternative or 1.8 acres for the Whittenton Alternative);

Chapter 4.14, *Biodiversity, Wildlife and Vegetation* addresses potential mitigation measures for direct and indirect impacts to vernal pools. The proposed wetland mitigation (establishment and restoration) areas could be designed to include new vernal pools to provide at least a 3:1 replacement of lost vernal

pool area (assuming the same mitigation ratio as for forested wetlands). Replacement vernal pools would be designed in accordance with the Corps' Guidelines for Vernal Pool Establishment.

Mitigation for vernal pool impacts would also be provided through preservation of vernal pool-upland complexes. Although MassDOT has not selected the final sites for wetland preservation, several of the potential preservation sites identified in the Wetland Mitigation Technical Report contain important vernal pool complexes:

- P9, Gobi Site
- P25, Rattlesnake Hill
- P26, Echo Pond
- T34B, Hockomock ACEC
- P36, Taunton River
- P52, Runnies River
- P53, Palmer River
- P56, Acidic Fen
- P58, Greenway Connection
- P59, Mattapoiset River Aquifer
- P62, BioReserve Infill

While the areas of potential mitigation are larger than the required mitigation, MassDOT would commit to constructing the amount of mitigation necessary to satisfy the required mitigation goals. At the current level of design for the project, proposed mitigation plans are not sufficiently accurate to determine the amount of wetland establishment that is practicable in a given area and will likely change when detailed field conditions are evaluated. The proposed mitigation plans cover larger areas than are required and allows for changes or reductions in the area of wetland mitigation from unknown site constraints.

Wetlands would generally be constructed by excavating wetland establishment sites to the appropriate elevation to establish a connection to groundwater hydrology. Wetland soils would be placed in the excavated areas to match the surrounding topography. Plantings would be installed at the sites to provide the appropriate vegetation cover types in the establishment sites. Sites would be monitored for a 10 year period after the completion of wetland construction to assess their development, hydrology, and functions and values.

Table 4.16-61 and Table 4.16-62 provide summaries of mitigation goals and potential mitigation totals by state and federal resource areas, respectively.

Table 4.16-61 Summary of Mitigation by State Resource Area

Site ID	Total Size	BVW (acre)	LUW (acre)	BLSF (acre)
A	5.4	5.4	-	4.9
B	6.5	6.5 [1]	-	-
C	1.7	1.7	-	1.5
D	3.5	3.5	-	3.1
E	4.3	4.3	-	3.2
F	0.4	-	0.4	0.4
G	61.3	54.7	6.6	-
Total Potential Mitigation (ac)	89.0	76.1	7.0	13.1
Required Mitigation (Stoughton)		19.2	1.9	6.7
Required Mitigation (Whittenton)		16.8	1.8	4.7

1 An additional 5.9 ac of forested upland would be created from this site.

Table 4.16-62 Summary of Mitigation by Cover Type[1] (acres)

Site ID	Total Size	OW	PEM	PSS	PFO
A	5.4	-	-	-	5.4
B	12.4	-	-	-	6.52
C	1.7	-	-	0.5	1.2
D	3.5	-	1.1	1.2	1.2
E	4.3	-	-	2.1	2.2
F	0.4	0.4	-	-	-
G	61.3	6.6	1.7	10.7	42.3
Total Potential Mitigation (ac)	89.0	7.0	2.8	14.5	58.8
Required Mitigation (Stoughton)		1.9	2.1	1.8	27.9
Required Mitigation (Whittenton)		1.8	1.2	1.8	25.7

1 Cowardin Types: OW = Open Water, PEM = Palustrine Emergent, PSS = Palustrine Scrub/Shrub PFO = Palustrine Forested.

2 An additional 5.9 ac of forested upland would be created from this site.

Both the Stoughton and Whittenton Alternatives of the South Coast Rail project would require a variance from the regulations of the WPA, an Individual Water Quality Certificate under Section 401 of the CWA, and an Individual Permit under Section 404 of the CWA. No alternative of the project that would satisfy the purpose and need of the project would avoid wetland impacts. As documented in this report, the South Coast Rail project addresses state and federal wetland regulations and meets the criteria for the required variances and permits needed to allow the proposed wetland impacts. Mitigation for those wetland impacts can be provided in compliance with the state and federal mitigation guidelines to offset the adverse impacts to wetland habitat, and functions and values of wetlands from the project.

Once a LEDPA is determined, the project would advance to a final design stage. This would require MassDOT to prepare a final set of engineering plans. This information would be used for the preparation of Notices of Intent (NOI) for each municipality along the right-of-way. Either alternative exceeds the area of alteration to BVW and would require the Commissioner of MassDEP to issue a variance from the performance standards of the WPA regulations. The procedure for requesting a variance includes first submitting the NOIs to the Conservation Commission for each municipality along the right-of-way. The

Commission in each municipality would be required to deny the proposed project in their Order of Conditions (OOC). MassDOT would then request that the MassDEP Southeast Regional Office issue a Superseding OOC (SOC) for the project. The Regional Office would be required to deny the proposed project in its SOC. MassDOT would then request that the Commissioner issue a variance.

Mitigation of Temporary Impacts

A range of measures would be implemented both during and immediately after the construction period to avoid and minimize temporary impacts to wetlands resulting from construction of the LEDPA. Potential measures that would be undertaken are described below. They include preventative measures as well as the in-kind restoration of regulated areas along the right-of-way and at bridges and culverts.

Minimization

An erosion and sedimentation control program would be implemented to minimize temporary impacts to wetland resource areas during the construction phase of the project. The program would incorporate Best Management Practices (BMPs) specified in guidelines developed by MA DEP and the USEPA through the development of a stormwater pollution prevention plan (SWPPP).

Proper implementation of the erosion and sedimentation control program would:

- Minimize exposed soil areas through sequencing and temporary stabilization
- Place structures to manage stormwater runoff and erosion; and
- Establish a permanent vegetative cover or other forms of stabilization as soon as practicable.

There are several structural and non-structural devices that would be implemented during the construction phase of the project to limit sediment movement, and to protect adjacent wetland resources from temporary impacts. An erosion control barrier would be installed upgradient of wetland resource areas and may consist of a barrier of hay bales and silt fence. Additional practices may include stabilized construction exits, catch basin inlet protection such as silt sacks, and dewatering filters if dewatering is required.

Mitigation of temporary construction-related impacts by erosion and sedimentation control may also include: temporary seeding, hay bale checkdams, and rock outlet protection. These BMPs aid in the reduction of erosion by stabilizing exposed soil surfaces and reducing flow velocities.

Restoration

Mitigation for construction period impacts would include in-kind and *in situ* replacement of resource areas. This restoration consists of several components, including regrading disturbed areas, replanting appropriate wetland vegetation, removing construction materials from the project area, and implementing an invasive species control plan.

Following the conclusion of construction, all temporarily impacted areas would be regraded and restored to match the adjacent wetland elevation. In locations where the placement of fill or other earthwork had occurred, stockpiled hydric topsoil or equivalent manufactured topsoil would be placed in the upper 12 inches of the soil profile. Planting plans for restoration areas would specify plant

materials appropriate to the type of wetland impacted in that location. As part of these planting plans, locations may also be seeded with an appropriate wetland seed mixture in order to provide rapid vegetative coverage to stabilize disturbed soils.

All debris would be removed from the work area. Hay bales used for sedimentation and erosion control would be broken up and spread as mulch in adjacent upland areas where possible, or would be removed from work area and disposed of properly outside of the project area.

An invasive species control plan would be implemented to prevent disturbed areas from becoming colonized by invasive species such as common reed. The invasive species control plan should include frequent eradication of invasive species during the initial period following construction to prevent the establishment of large populations that could spread to adjacent undisturbed areas.

Upon completion of work, temporarily impacted upland areas adjacent to wetland restoration areas would be regraded. Areas of exposed soils would be seeded with a wildlife/conservation grass mixture to provide permanent stabilization and erosion control. The seeded slopes would be temporarily mulched with loose hay to prevent erosion before the seeds germinate and take root.

4.16.11 Regulatory Compliance of the Alternatives

Proposed work and its associated impacts would be subject to regulatory review with respect to state and federal wetlands regulatory programs, as described below.

4.16.11.1 Massachusetts Wetlands Protection Act (WPA)

The Massachusetts Wetlands Protection Act (WPA) regulations (310 CMR 10.00) establish specific mitigation requirements for the majority of wetland resource areas. Performance standards are outlined for work performed in each of the wetland resources regulated under the Massachusetts State Wetlands Regulations. The following sections list these performance standards by resource type except for Land Subject to Coastal Storm Flowage (LSCSF) for which there are no performance standards.

The South Coast Rail project cannot fully comply with the performance standards of the WPA, and will require a variance under 310 CMR 10.05(10) (a). This regulation allows performance standards to be waived in the event that: “mitigating measures are proposed that will allow the project to be conditioned so as to contribute to the protection of the interests identified in M.G.L. c. 131 §40.” The regulation also requires that “there are no reasonable conditions or alternatives that would allow the project to proceed in compliance” with the regulations of the Act, and that “the variance is necessary to accommodate an overriding community, regional, state or national public interest.” MassDOT has prepared data in the Technical Reports for the FEIS/FEIR intended to demonstrate that the conditions for granting a waiver have been met. However, MADEP is the final arbiter as to whether MassDOT has met the necessary regulatory requirements for a variance. MassDOT will attempt to design mitigation for the project that complies with the resource area standards to the maximum extent practicable.

This section discusses the project’s compliance with the performance standards established for each resource area and the need for a variance to proceed with the project.

Performance Standards

Performance standards are outlined for work performed in each of the wetland resources regulated under the Massachusetts State Wetlands Regulations.[43] The following sections list these performance standards by resource type except for Land Subject to Coastal Storm Flowage for which there are no performance standards.

Bank

The regulations for Bank (310 CMR 10.54(4)) do not specify mitigation requirements, but do list general performance standards that require that work on a Bank not impair any of the following:

(a) The physical stability of the Bank;

(b) The water carrying capacity of the existing channel within the Bank;

(c) Ground water and surface water quality;

(d) The capacity of the Bank to provide breeding habitat, escape and food cover for fisheries; and

(e) The capacity of the Bank to provide important wildlife habitat functions.

Where Bank is significant to important wildlife habitat functions, the regulations at 310 CMR 10.60(3) apply. These regulations require that alterations of wildlife habitat characteristics beyond permissible thresholds (for Bank, 50 linear feet) be restored onsite or replicated offsite in accordance with the following general conditions:

(a) The surface of the replacement area to be created shall be equal to that of the area that will be lost;

(b) The elevation of groundwater relative to the surface of the replacement area shall be approximately equal to that of the lost area;

(c) The replacement area shall be located within the same general area as the lost area. In the case of banks and land under water, the replacement area shall be located on the same water body or waterway if the latter has not been rechanneled or otherwise relocated. In the case of bordering land subject to flooding, the replacement area shall be located approximately the same distance from the water body or waterway as the lost area. In the case of vernal pool habitat, the replacement area shall be located in close proximity to the lost area;

(d) Interspersion and diversity of vegetation, water and other wildlife habitat characteristics of the replacement area, as well as its location relative to neighboring wildlife habitats, shall be similar to that of the lost areas, insofar as necessary to maintain the wildlife habitat functions of the lost area;

[43] 310 Code of Massachusetts Regulations (CMR) 10.00. Revised June 2009

(e) The project shall not alter ten or more acres of Land Subject to Flooding (LSF) or Land Under Water (LUW) found to be significant to the protection of wildlife habitat, or 2,000 feet or more of Bank found to be significant to the protection of wildlife habitat (in the case of a bank of a stream or river, this shall be measured as each side of said stream or river);

(f) If the replacement area is located in an area subject to M.G.L. c. 131 §40, there shall be no adverse effect on the existing important wildlife habitat functions of said area as measured by the standards of 310 CMR 10.60;

(g) The "thresholds" established in 310 CMR 10.54(4)(a)(5)m, 10.56(4)(a)4, 10.57(4)(a)3, and 10.58(4)(d)1.c (below which alterations of resource areas are not deemed to impair capacity to provide important wildlife habitat functions) shall not apply to any replacement area; and

(h) The replacement area shall be provided in a manner which is consistent with all other General Performance Standards for each resource area in 310 CMR 10.51 through 10.60.

Bordering Vegetated Wetlands (BVW)

For work proposed within BVW, the following performance standards apply:

- Any proposed work in a BVW shall not destroy or impair any portion of the said area;
- The issuing authority may issue an Order of Conditions permitting work, which results in the loss of up to 5,000 square feet of BVW when said area is replaced in accordance with the following general conditions and any additional, specific conditions the issuing authority deems necessary to ensure that the replacement area would function in a manner similar to the area that would be lost;
- No project may be permitted that would have any adverse effect on the specified habitat sites of rare vertebrate or invertebrate species; and
- Any proposed work shall not destroy or otherwise impair any portion of a BVW that is within an ACEC designated by the Secretary of Environmental Affairs.

The regulations at 310 CMR 10.55(4)(b) establish seven general performance standards for replacement of lost BVW. Although the South Coast Rail project does not comply with the performance standard limiting BVW loss to 5,000 square feet and will therefore require a variance, the subsequent performance standards are applicable.

- The issuing authority may issue an Order of Conditions permitting work, which results in the loss of up to 5,000 square feet of BVW when said area is replaced in accordance with the following general conditions and any additional, specific conditions the issuing authority deems necessary to ensure that the replacement area would function in a manner similar to the area that would be lost;
- The surface of the replacement area to be created shall be equal to that of the area that will be lost (the MassDEP has determined that projects requiring a variance should provide replacement wetland area at a 2:1 ratio);

- The elevation of groundwater relative to the surface of the replacement area shall be approximately equal to that of the lost area;
- The overall horizontal configuration and location of the replacement area with respect to the bank shall be similar to that of the lost area;
- The replacement area shall have an unrestricted hydraulic connection to the same water body or waterway associated with the lost area;
- The replacement area shall be located within the same general area of the water body or reach of the waterway as the lost area;
- At least 75 percent of the surface of the replacement area shall be reestablished with indigenous wetland plant species within two growing seasons, and prior to said vegetative reestablishment any exposed soil in the replacement area shall be temporarily stabilized to prevent erosion in accordance with standard U.S. Soil Conservation Service methods; and
- The replacement area shall be provided in a manner that is consistent with all other General Performance Standards for each resource area in Part III of 310 CMR 10.00.

Land Under Waterbodies and Waterways (LUWW)

The regulations for Land Under Water Bodies and Waterways (LUWW) (310 CMR 10.56(4)) do not specify mitigation requirements, but do list general performance standards, which require that work within LUWW not impair any of the following:

(a) The water carrying capacity within the defined channel, which is provided by said land in conjunction with the banks;

(b) Ground and surface water quality;

(c) The capacity of said land to provide breeding habitat, escape cover and food for fisheries; and

(d) The capacity of said land to provide important wildlife habitat functions.

Where LUWW is significant to important wildlife habitat functions, the regulatory standards at 310 CMR 10.60(3) apply. These regulations require that alterations of wildlife habitat characteristics beyond permissible thresholds (for LUWW, 5,000 square feet) be restored onsite or replicated offsite in accordance with the general conditions listed above for Bank.

Bordering Land Subject to Flooding (BLSF)

For work proposed in BLSF, the following performance standards apply:

- Compensatory flood storage shall be provided for all flood storage volume that would be lost as the result of a proposed project within BLSF. Such compensatory volume shall have an unrestricted hydraulic connection to the same waterway or waterbody. Further, with respect to waterways, such compensatory volume shall be provided within the same reach of the river, stream or creek;

- Work within BLSF, including that work required to provide the compensatory flood storage specified above, shall not restrict flows so as to cause an increase in flood stage or velocity; and

Work in those portions of bordering land subject to flooding found to be significant to the protection of wildlife habitat shall not impair its capacity to provide important wildlife habitat functions. Where this resource is significant to important wildlife habitat functions, the regulatory standards at 310 CMR 10.60(3) apply. These regulations require that alterations of wildlife habitat characteristics beyond permissible thresholds (for BLSF, 5,000 square feet) be restored onsite or replicated offsite in accordance with the general conditions listed above for Bank.

Riverfront Area

The performance standards for Riverfront Area (310 CMR 10.58(4)) do not specify mitigation requirements. However, where this resource is significant to important wildlife habitat functions, the regulatory standards at 310 CMR 10.60(3) apply. These regulations require that alterations of wildlife habitat characteristics beyond permissible thresholds (for Riverfront Area, 5,000 square feet) be restored onsite or replicated offsite in accordance with the six general conditions listed above for Bank.

Coastal Bank

There are no specific mitigation requirements for work on Coastal Bank. The regulations at 310 CMR 10.30(6) require that any project on a coastal bank shall have no adverse effects on the stability of the coastal bank. Compliance with this performance standard would require that alterations of Coastal Bank be mitigated on-site through measures to ensure stability.

Build Alternatives

None of the Build Alternatives would meet all of the performance standards outlined for each resource protected under the Act. Construction of any of the Build Alternatives would therefore require the Commissioner of MA DEP to issue a variance from the WPA regulations.

Bank

Each of the proposed alternatives would alter Bank for reconstruction and rehabilitation of the rail bed and bridges. Generally, the altered bank is directly adjacent to the rail bed at a bridge or culvert associated with a stream crossing. The replacement or extension of culverts and bridge abutments would be designed and constructed in such a way as to maintain physical stability of the bank, and water carrying capacity. Construction would be done using appropriate erosion and sedimentation control measures to protect water quality.

Alterations of bank at existing bridges or culverts would be temporary in nature, except in locations where additional tracks are added. In most cases, existing bridge abutments or culverts provide minimal important wildlife habitat. All areas of temporarily altered bank would be restored in-kind.

At locations where culvert extensions or enlarged bridge abutments would be required, wildlife habitat evaluations would be performed to determine the capacity of the bank to provide wildlife habitat functions. Bridges and culverts would be designed to maintain the physical stability and water carrying capacity of the channel. The wetland habitat evaluations would be used to guide mitigation efforts to restore lost habitat functions within the project area. Where necessary, permanently altered bank could

be relocated and reconstructed as mitigation to meet the performance standards (unless impacts occur within rare species habitat). Detailed designs for bank replacement would be developed in a later design phase, once the LEDPA is determined. This would be done in consultation with MA DEP and the local Conservation Commissions.

Bordering Vegetated Wetlands

Each of the proposed alternatives would result in the loss of over 5,000 square feet of BVW and would result in the loss of BVW within endangered and protected species habitat. There would be loss of BVW in an ACEC along the Stoughton and Whittenton Alternatives. These losses do not conform to the WPA performance standards and would require a Variance from the Commissioner of DEP.

Land Under Waterbodies and Waterways (LUWW)

Specific impacts to LUWW would be calculated in the final design phase for the LEDPA. It is expected that impacts would be minor and associated with the replacement of bridges and culverts. All impacts would be mitigated for and proposed work would not alter the carrying capacity of the channel, the water quality, or wildlife habitat. Each of the Alternatives can be constructed in conformance with the performance standards and would not require a Variance from the Commissioner of MA DEP for work occurring in LUWW (unless the impacts occur within rare species habitat).

Bordering Land Subject to Flooding (BLSF)

Each of the proposed Alternatives would result in losses to BLSF and losses within areas of protected habitat for Rare or Protected species. This does not conform to the performance standards outlined in the Act and work along any of the proposed Alternatives would require a Variance from the Commissioner of MA DEP for work proposed within BLSF.

Riverfront Area

Work within Riverfront Area is unavoidable along each of the proposed alternatives due to the location of the rights-of-way and the number of perennial streams that each crosses. Although primarily redevelopment, portions of work proposed within Riverfront Area would occur within habitat of protected or rare species and would not conform to the performance standards. A Variance from the Commissioner of MA DEP would be required for work along any of the proposed alternatives if the performance standards could not be met. During a subsequent design phase, the project's ability to comply with the compensatory storage performance standard and wildlife habitat performance standard would be evaluated to determine if a variance is required.

Coastal Bank

The Fall River Secondary is the only proposed alternative that would impact Coastal Bank. Work in these areas consists of reconstruction and would meet all the performance standards outlined in the Act. A variance would not be required for work within Coastal Bank.

4.16.11.2 Water Quality Certification – Section 401

Section 401 of the Federal Clean Water Act requires any applicant for a federal license or permit to conduct any activity that may result in a discharge of a pollutant into waters of the United States to obtain a certification from the State in which the discharge originates or would originate that the

discharge will comply with the applicable (i.e., Commonwealth of Massachusetts) water quality standards. MA DEP executes its responsibilities pursuant to Section 401 under the Massachusetts Clean Water Act (M.G.L. c 21 §§ 26-53) and is the final arbiter as to whether a water quality certification will be issued, denied, or waived. The Order of Conditions issued by local conservation commissions automatically assumes the issuance of a water quality certificate for projects impacting less than 5,000 square feet of wetlands. This project would require MassDOT to obtain an Individual Water Quality Certificate from MA DEP as impacts would exceed 5,000 square feet.

There are seven criteria for the evaluation of applications for discharge of dredge or fill material (314 CMR 9.06):

- No discharge of dredged or fill material shall be permitted if there is a practicable alternative to the proposed discharge that would have less adverse impact on the aquatic ecosystem;
- No discharge of dredged or fill material shall be permitted unless appropriate and practicable steps have been taken that would minimize potential adverse impacts to the bordering or isolated vegetated wetlands or land under water, including a minimum of 1:1 restoration or replication of isolated or bordering wetlands;
- No discharge of dredged or fill material shall be permitted to ORWs, except for the activities specified in 314 CMR 9.06(3)(a) through (I), which remain subject to an alternatives analysis and other requirements of 314 CMR 9.06;
- Discharge of dredged or fill material to an ORW specifically identified in 314 CMR 4.06(1)(d) (e.g., vernal pool, within 400 feet of a water supply reservoir and any other area so designated) is prohibited as provided therein unless a variance is obtained under 314 CMR 9.08;
- No discharge of dredged or fill material is permitted for the impoundment or detention of stormwater for the purposes of controlling sedimentation or other pollutant attenuation;
- Stormwater discharges shall be provided with BMPs to attenuate pollutants and provide a set back from receiving water or wetland; and
- No discharge of dredged or fill material shall be permitted in the rare circumstances where the activity meets the criteria for evaluation but would result in substantial adverse impacts to the physical, chemical, or biological integrity of surface waters of the Commonwealth.

One of the seven criteria for the evaluation of applications for discharge of dredge or fill material (314 CMR 9.06(2)) is relevant to mitigation:

- No discharge of dredged or fill material shall be permitted unless appropriate and practicable steps have been taken that would minimize potential adverse impacts to the bordering or isolated vegetated wetlands or land under water, including a minimum of 1:1 restoration or replication of isolated or bordering wetlands.

No-Build Alternative

The No-Build Alternative requires no construction and would not result in any impacts to wetland resources areas. A water quality certificate would not be required for this alternative.

Stoughton Alternatives

The Stoughton Alternatives comply with the criteria outlined for the discharge of dredged or fill material within waterways. Compliance with the criteria outlined in 310 CMR 9.06 is explained below. Based on the methodology used for delineating the boundaries of vernal pools, the Stoughton Alternatives would require fill in ORWs (based on the presence of one or more vernal pools) and would not meet performance standards for the discharge of dredged or fill material in ORWs.

No dredging or fill is planned in conjunction with the construction of stormwater management systems proposed as part of this project, and the proposed stormwater systems proposed at station sites and layover facilities include BMPs and setbacks as outlined in the Stormwater Management Regulations.

Whittenton Alternatives

The Whittenton Alternatives comply with the criteria outlined for the discharge of dredged or fill material within waterways. Compliance with the criteria outlined in 310 CMR 9.06 is explained below.

Based upon the methodology used for delineating the boundaries of vernal pools, the Whittenton Alternatives would require fill in ORWs (based on the presence of one or more vernal pools) and would not meet performance standards for the discharge of dredged or fill material in ORWs.

No dredging or fill is planned in conjunction with the construction of stormwater management systems proposed as part of this project, and the proposed stormwater systems proposed at station sites and layover facilities include BMPs and setbacks as outlined in the Stormwater Management Regulations.

4.16.11.3 Section 404 of the Clean Water Act

Section 404 of the Clean Water Act requires a Department of the Army permit for the discharge of dredged or fill material into waters of the United States, including adjacent wetlands. The Build Alternatives would require the issuance of an Individual Section 404 Permit (i.e., would not be eligible for the Massachusetts Programmatic General Permit) because they would result in the loss of more than one acre of vegetated wetland, as described in the preceding analyses.

The Build Alternatives would require a Section 404 permit for the placement of fill in freshwater wetlands. The wetland filling is evaluated, in part, using the US EPA Guidelines for Specification of Disposal Sites for Dredged or Fill Material promulgated pursuant to Section 404(b) (1) of the Clean Water Act (Section 404(b)(1) Guidelines) and its implementing regulations at 40 CFR 230 *et seq*. The Guidelines are intended to avoid unnecessary filling of waters and wetlands. Two of the guidelines are relevant to mitigation:

- No discharge of dredged or fill material shall be permitted if there is a practicable alternative to the proposed discharge that would have less adverse impact on the aquatic ecosystem, so long as the alternative does not have other significant adverse environmental consequences; and

- No discharge of dredged or fill material shall be permitted unless appropriate and practicable steps have been taken that will minimize adverse effects of the discharge on the aquatic ecosystem.

In setting mitigation requirements for Section 404 permits, the USACE considers watershed needs, mix of habitat types, and compatibility with adjacent land use.

The USACE issued rules for compensatory wetland mitigation (33 CFR Parts 325 and 332) in April 2008. This guidance emphasizes a watershed approach to selecting compensatory mitigation measures and locations. Five types of compensatory mitigation are recognized:

- Establishment (creation), defined as: "the manipulation of the physical, chemical, or biological characteristics present to develop an aquatic resource that did not previously exist at an upland site. Establishment results in a gain in aquatic resource area and functions."

- Re-establishment: "the manipulation of the physical, chemical, or biological characteristics of a site with the goal of returning natural/historic functions to a former aquatic resource. Re-establishment results in rebuilding a former aquatic resource and results in a gain in aquatic resource area and functions." In the past, this was generally referred to as "restoration."

- Rehabilitation: "the manipulation of the physical, chemical, or biological characteristics of a site with the goal of repairing natural/historic functions to a degraded aquatic resource. Rehabilitation results in a gain in aquatic resource function, but does not result in a gain in aquatic resource area."

- Enhancement: "the manipulation of the physical, chemical, or biological characteristics of an aquatic resource to heighten, intensify, or improve a specific aquatic resource function(s). Enhancement results in the gain of selected aquatic resource function(s), but may also lead to a decline in other aquatic resource function(s). Enhancement does not result in a gain in aquatic resource area."

- Preservation: "the removal of a threat to, or preventing the decline of, aquatic resources by an action in or near those aquatic resources. This term includes activities commonly associated with the protection and maintenance of aquatic resources through the implementation of appropriate legal and physical mechanisms. Preservation does not result in a gain of aquatic resource area or functions."

The New England District has published a guidance[44] document for compensatory mitigation that establishes certain mitigation ratios for permanent impacts. For purposes of calculating federal mitigation goals, it is assumed that the wetland restoration standard would be applied. Using this formula assuming that wetland restoration would be required for permanent impacts, a 1:1 minimum ratio is required for impacts to areas of open water, a 2:1 minimum ratio is required for permanent to

[44] USACE. 2010. New England District Compensatory Mitigation Guidance. New England District, U.S. Army Corps of Engineers, July 20, 2010. Available online at: <http://www.nae.usace.army.mil/Portals/74/docs/regulatory/Mitigation/CompensatoryMitigationGuidance.pdf> (April 26, 2013).

emergent wetlands, a 2:1 minimum ratio is required for impacts to scrub shrub wetlands, and a 3:1 minimum ratio is required for impacts to forested wetlands. Temporary impacts are also addressed in the guidance document, with most impacts requiring the replacement of a given percentage of the impacted area. Meetings between MassDOT and reviewing agencies, described in more detail in Chapter 5, agreed upon replacement ratios of 1:1 for temporary impacts to either emergent wetlands or scrub-shrub wetlands, to be replaced in-situ, and 1.5:1 for temporary impacts to forested wetlands, to be replaced in-situ as well as offsite.

The regulations recognize that mitigation may be located on site (at or adjacent to the impact site) or off site (at another location in the same watershed). Wetland mitigation banks, where available, and in lieu fee programs, where available, may also be used to mitigate for unavoidable impacts. Neither of these programs currently exists in Massachusetts. However, the USACE recently (October 2, 2012) issued a public notice seeking comments on a "Prospectus for a State-Wide In-Lieu Fee Program Administered by the Massachusetts Department of Fish and Game." The In-Lieu Fee (ILF) program would allow all applicants for Section 404 permits to pay into a trust fund administered by the Department of Fish and Game (DFG), who would then propose compensatory mitigation projects. The USACE would determine which projects were eligible to be used in the ILF program. Permittees would purchase mitigation credits, based on a ratio to be determined. If this program is implemented, it may impact the mitigation strategy for the project. MassDOT would consult with the USACE and review agencies to examine this option should it arise.

These regulations also recognize that compensatory mitigation must be commensurate with the amount and type of impact, and requires that the Corps determine what is practicable and capable of compensating for the aquatic resource function that would be lost, and what is environmentally preferable. Considerations include:

- The likelihood for ecological success;
- The location relative to the impact site;
- The significance within the watershed; and
- The costs of the compensatory mitigation project.

These regulations require a watershed-based approach, ideally based on an existing watershed plan that provides information on the land uses, natural habitats, water quality, and aquatic resources within a watershed. The goal of using a watershed approach is to maintain and improve the quality and quantity of aquatic resources within a watershed, by strategically siting compensatory mitigation sites.

Practicable Alternatives

Practicable means available and capable of being done after taking into consideration cost, existing technology, and logistics in light of overall project purposes.[45] In considering whether an alternative is practicable, due consideration must be given to cost, constructability, existing technology and also to logistical considerations such as traffic flow and safety in and around each particular alignment and station location. The practicability of the alternatives is considered in the Corps' determination of the

[45] 40 CFR 230.3(q)

LEDPA. Once a LEDPA is determined, the project would advance to a final design stage. This would require MassDOT to prepare a final set of engineering plans.

Water Quality/Threatened and Endangered Species

The Build Alternatives include proposed stormwater management systems intended to mitigate potential impacts to water quality by controlling runoff velocities and removing pollutants from the stormwater runoff discharging from station locations to downstream surface water resources. The proposed project has been designed to comply with Massachusetts Stormwater Standards.[46] Due to the proposed impacts to ORWs, the Build Alternatives would require a variance from the state water quality standards (Section 401).

The Build Alternatives would seemingly not affect any federally-listed endangered species, because there are none within the immediate project area. Habitat for several state listed species occurs within or immediately adjacent to the right-of-way. This is described in detail in Chapter 4.14, *Biodiversity. Wildlife and Vegetation* and Chapter 4.15, *Threatened and Endangered Species*.

No Significant Degradation

The 404(b)(1) Guidelines stipulate that no discharge of dredged or fill material shall be permitted that will cause or contribute to significant degradation of the waters of the United States.[47] Measures to protect and avoid impacts to wetlands and water resources were incorporated into the design process of the Build Alternatives and will be further refined for the LEDPA. Construction practices will be implemented in accordance with state and federal guidelines to prevent unnecessary impacts to wetland and water resources. Water resources are further described in Chapter 4.17, *Water Resources*.

Reasonable Steps to Minimize Adverse Effects

The 404(b)(1) Guidelines further stipulate that no discharge of dredged or fill material shall be permitted unless appropriate and practicable steps have been taken that will minimize potential adverse impacts of the discharge on the aquatic ecosystem, To the extent practicable, adverse effects to wetland resources will be minimized through avoidance, minimization, and compensatory mitigation.

Avoidance

Avoidance of all direct wetland impacts would only be possible by implementing the No-Build Alternative. Section 4.16.10.1 of this chapter describes specific measures incorporated into the design process to incorporate avoidance of impacts into each of the Build Alternatives.

Minimization

Special construction techniques, such as retaining walls, have been incorporated into the design of the Build Alternatives to further minimize adverse impacts to wetlands. A full description of the measures taken to minimize wetland impacts is provided above in Section 4.16.10.1.

---

[46] 310 Code of Massachusetts Regulations (CMR) 10.05(6) (k).
[47] 40 CFR 230.10(c)

Mitigation

Mitigation would be provided to offset all losses of wetland and other aquatic resource functions and values. Section 4.16.10 identifies the methodology that would be used to identify locations and presents the mitigation goals that would provide replacement of lost areas as well as functions and values. Mitigation areas would be designated within the same watershed as the lost area whenever possible. Once the LEDPA is determined, specific mitigation sites would be identified and conceptual mitigation designs prepared.

4.17 WATER RESOURCES

4.17.1 Introduction

This chapter discusses the existing water resources within and adjacent to the South Coast Rail project corridors and potential impacts to water resources and water supply protection areas within the study area. This section provides background information on the South Coast Rail project as well as general information on water resources regulations. Section 4.17.2 identifies water resources in the project study area and defines the regulatory categories for water resources and the specific water resources in proximity to each of the alternatives. Section 4.17.3 describes potential impacts and mitigation associated with the alternatives under consideration.

4.17.1.1 Resource Definition

Surface and groundwater are important natural resources that have a variety of uses including public drinking water, irrigation, industrial, and wildlife habitat. Water quality is determined by the amount of dissolved or suspended material that the water may contain. The quality of surface water and groundwater is influenced by surficial geology, land use, and water quality of source waters. The use of water may be limited by its physical and chemical characteristics. Changes in temperature, pH, dissolved oxygen (DO) content, and pollutant concentrations may make surface waters or groundwater unsuitable for their existing uses.

The quality of a surface waterbody is largely determined by the terrain and condition of its contributing watershed. Pollutant sources can include point sources, such as municipal wastewater treatment plants and industrial discharges, with varying concentrations of particles and/or chemicals, as well as non-point sources, such as stormwater runoff, from farmland, containing sediment, fertilizer and pesticides.

Groundwater quality may also be affected by aboveground pollutant sources. Precipitation that infiltrates through the soil to the water table may carry pollutants encountered on the surface or in the soil. However, aquifers are often buffered from surface influences by underground hydrogeologic features, such as different soil types. Layers of clay may impede infiltration, preventing water from reaching the aquifer, while layers of sand may filter out many contaminants as the water travels through the soil. Drinking water wells are often located in highly-permeable soils to maximize potential pumping rates. These same soils can allow accidental spills to reach the well quickly, especially if the spills are close to the well itself. Therefore, protection of groundwater supplies must consider potential pollutant sources, well locations, and soil conditions.

The information presented in the following sections describes the surface and groundwater resources located adjacent to the alignments of the alternatives under consideration. Resources assessed include named surface waters such as rivers and lakes as well as public drinking water wells. Information on the existing quality and usage of these resources is based on publicly accessible information, including the *Massachusetts Integrated List of Waters*.[1]

[1] Massachusetts Department of Environmental Protection, Division of Watershed Management. *Massachusetts Year 2006 Integrated List of Waters*. October 2007.

4.17.1.2 Regulatory Context and Significance

Surface and groundwater resources are protected under several state and federal regulatory programs, including the federal Clean Water Act (Sections 402 and 404) and the Massachusetts Clean Waters Act (MGL Chapter 21, §26-53). Other applicable regulations include the Massachusetts Section 401 Discharge regulations (314 CMR 9.00), Groundwater Quality Standards (314 CMR 6.00), and Surface Water Quality Standards (314 CMR 4.00). Some waterways are also regulated under MGL Chapter 91, which protects the public interest in tidelands, Great Ponds, and non-tidal rivers.

Clean Water Act of 1977

Water quality must be addressed for compliance with the Federal Water Pollution Control Act, also known as the Clean Water Act, which provides the authority to the USEPA to establish water quality standards (or to states to establish standards equal to or more stringent than USEPA standards), to control discharges into surface and subsurface waters, to develop waste treatment management plans and practices. It requires states to monitor and classify waterbodies, establish goals, and publish lists of monitoring and classification results. The Clean Water Act gives states the authority and responsibility to publish water quality standards.[2]

Section 303(d) of the Clean Water Act

Section 303(d) of the Clean Water Act also establishes the Total Maximum Daily Load (TMDL) program. A TMDL is the allowable load of a single pollutant from all point and non-point sources to a waterbody. Under the TMDL program, states establish priority rankings for their waterbodies and identify the uses for these waterbodies (e.g., drinking water supply, recreation, etc.). TMDLs can then be set for individual pollutants to ensure that the quality is adequate for the designated uses. The USEPA must approve or disapprove any TMDL established by the state. If the USEPA disapproves a TMDL, it must set the TMDL itself.

If a project impacts a TMDL-listed waterbody, appropriate measures must be taken to control the discharge of the listed pollutant and meet the TMDL requirements. Some TMDLs may require additional measures (including stormwater treatment) in order to prevent an increase in pollutant loading to the receiving water.

Section 404 of the Clean Water Act

Section 404 of the Clean Water Act requires a Department of the Army permit (administered by the U.S. Army Corps of Engineers) for the discharge of dredged or fill material into waters of the United States, including adjacent wetlands. Any of the South Coast Rail Build Alternatives under consideration would require the issuance of an Individual Section 404 Permit (i.e., would not be eligible for the Corps' Massachusetts General Permit) if it results in the loss of more than 1 acre of waters of the United States.

The alternatives would require a Section 404 permit for the placement of fill in wetlands. The wetland filling is evaluated by the Corps using the U.S. Environmental Protection Agency Guidelines for Specification of Disposal Sites for Dredged or Fill Material (Section 404(b)(1) Guidelines). The Section 404(b) (1) guidelines are designed to avoid unnecessary filling of waters and wetlands.

[2] U.S. Code. Title 33, Chapter 26 – *Water Pollution Prevention and Control*. (November 27, 2002).

The Section 404(b)(1) Guidelines stipulate (in part) that:

- No discharge of dredged or fill material shall be permitted if there is a practicable alternative to the proposed discharge which would have less adverse impact on the aquatic ecosystem, so long as the alternative does not have other significant adverse environmental consequences;
- No discharge of dredged or fill material shall be permitted if it: (1) causes or contributes to violations of any applicable State water quality standard; (2) violates any applicable toxic effluent standard or prohibition under Section 307 of the Clean Water Act; (3) Jeopardizes the continued existence of species listed as threatened or endangered under the Endangered Species Act; or (4) Violates any requirement imposed by the Secretary of Commerce to protect any marine sanctuary designated under the Marine Protection, Research and Sanctuaries Act of 1972.
- No discharge of dredged or fill material shall be permitted which will cause or contribute to significant degradation of the waters of the United States.
- No discharge of dredged or fill material shall be permitted unless appropriate and practicable steps have been taken which will minimize adverse effects of the discharge on the aquatic ecosystem

Safe Drinking Water Act

The Safe Drinking Water Act authorizes the USEPA to set national health-based standards for drinking water to protect against both naturally-occurring and man-made contaminants that may be found in drinking water.[3] If the project impacts a drinking water supply, appropriate mitigation measures must be provided to maintain compliance with the Safe Drinking Water Act.

USEPA NPDES Construction Permit

All South Coast Rail Build Alternatives would require a National Pollutant Discharge Elimination System (NPDES) Construction Permit pursuant to Section 402 of the Clean Water Act, which regulates erosion control, pollution prevention, and other stormwater management issues at construction sites over 1 acre. This permit would include a Stormwater Pollution Prevention Plan (SWPPP) that would specify proper stormwater management procedures for any disturbed areas.

Water Quality Certificate

Section 401 of the Clean Water Act (33 U.S.C. 1341) requires any applicant for a federal license or permit to conduct any activity that may result in a discharge of a pollutant into waters of the United States to obtain a certification from the state in which the discharge originates or would originate, that the discharge will comply with the applicable effluent limitations and water quality standards.[4] In addition, the MassDEP is required to issue Water Quality Certifications for projects that result in discharge of fill to a wetland or waterbody, pursuant to the Massachusetts Clean Waters Act (MGL Ch. 21 § 26-53). This project will require issuance of an individual Water Quality Certification if it results in the loss of more

[3] U.S. Code. Title 42, Chapter 6A, Subchapter XII – *Safety of Public Water Systems*. (January 6, 2003).
[4] 33 CFR 320.3(a)

than 5,000 square feet of wetlands subject to federal jurisdiction or places fill in Outstanding Resource Water (ORW).

Massachusetts Stormwater Management Standards and Regulations

The Build Alternatives would require work within Wetland Resource Areas and buffer zones as defined and regulated under the Massachusetts WPA. Projects that fall under the jurisdiction of the WPA must comply with the Massachusetts Stormwater Management Standards included in the WPA regulations (310 CMR 10). The Stormwater Management Standards define the requirements for proper stormwater management for new or re-development sites in the State of Massachusetts. The water quality issues addressed by the standards include erosion control, peak discharge rates, groundwater recharge, total suspended solids (TSS) removal, wellhead protection, construction management, long-term maintenance, and illicit (non-stormwater) discharges to the stormwater management system. Additional stormwater regulations (310 CMR 21) have been proposed by MassDEP that apply treatment requirements to projects in TMDL areas, impose restrictions on discharges to water supply protection areas, and require infiltration to offset the effects of impervious surfaces on runoff and groundwater recharge.

Chapter 91 Waterways License

The Massachusetts Public Waterfront Act (MGL Chapter 91) gives MassDEP jurisdiction over dredging, filling, construction, demolition, and changes in use within flowed tidelands, filled tidelands, Great Ponds (ponds covering over 10 acres in their natural states), and any non-tidal navigable streams on which public funds have been expended. The proposed project may require a Waterways License due to the construction of new or modified crossings over navigable streams.

National Wild and Scenic Rivers Act

The National Wild and Scenic Rivers Act (Public Law 90-542; 16 U.S.C. 1271 et seq.) was established to preserve the free-flowing conditions of rivers with outstanding natural, cultural, and recreational values. Designation of an entire river system, or segments of, is approved by Congress or the Secretary of the Interior. Rivers are then classified as Wild: free of impoundments, generally inaccessible (except by trail), with primitive watersheds/shorelines unpolluted waters; Scenic: free of impoundments, largely undeveloped watersheds/shorelines and accessible in places by roads; or Recreational: readily accessible by road or railroad with some development along their shorelines and some past impoundments or diversions. The administration of designated rivers is assigned to a federal or state agency.

The Taunton River was designated as a Wild and Scenic River on March 30, 2009; therefore, the Build Alternatives are subject to the Wild and Scenic Rivers Act provisions. The administration of this designation occurs through a partnership between the National Park Service and the Taunton River Stewardship Council. The entire river system was included in this designation from its headwaters at the confluence of the Town and Matfield rivers in Bridgewater downstream 40 miles to the confluence with the Quequechan River at the Interstate 195 Bridge in Fall River. Twenty-six miles of the Taunton River were classified as Scenic and 14 miles as Recreational.

The Act prohibits federal support for actions such as the construction of dams or other in stream activities that would harm the river's free-flowing condition, water quality, or Outstanding Resource Values (scenic, recreational, geologic, fish and wildlife, historic, cultural, or other similar values).[5] However, it does not prohibit development near designated rivers; rather it encourages regional river management practices to protect the use and enjoyment of these rivers. New development on federal lands must be guided by land use and resource management objectives that are compatible with the river's classification.

4.17.2 Existing Conditions

This section describes the existing conditions of surface water resources and public water supply wells that could be affected by the South Coast Rail project alternatives presented in the FEIS/FEIR and identifies the specific resources that could be affected under these alternatives. Figure 4.17-1 shows the project area and major waterbodies. Figure 1.4-1 illustrates the alternative alignments and proposed station locations, in relation to these waterbodies.

4.17.2.1 Regional Overview

This section summarizes the relevant local water resources and explains regulatory classifications for surface and groundwater protection.

Surface Water Resources

A screening for surface water resources was performed to identify all waterbodies that would be crossed by or within 100 feet of the centerlines of the alternatives under consideration. This process used geographic information systems (GIS) data developed by the U.S. Geological Survey (USGS) and provided by MassGIS to identify named and unnamed waterbodies. Since this screening is based only on the conceptual routes taken by the alternatives, further analysis will be necessary to determine if the construction and operation of the alternatives result in any actual impacts to these waterbodies.

The screening process identified numerous named rivers, streams, and ponds as well as unnamed, minor waterbodies. The named waterbodies are listed in Table 4.17-1.

In Massachusetts, certain surface waters with exceptional socioeconomic, recreational, ecological, or aesthetic values are designated ORWs, which require additional protection. ORWs can include drinking water supplies as well as high-value wetlands areas (specified in 314 CMR 4.06[2]) such as ACECs. The Hockomock Swamp ACEC and its associated wetlands and water bodies are described by the Massachusetts DCR as the largest vegetated freshwater wetland system in Massachusetts. The only Hockomock Swamp ACEC waterbody that would be affected by the project is Black Brook in Easton (included in Table 4.17-1). The East Branch of the Neponset River flows into the Fowl Meadow and Ponkapoag Bog ACEC and may be affected by the project. The Three Mile River ACEC is also located within the project area as presented in the DEIS/DEIR but is no longer affected by stormwater discharges from project elements. Further information regarding ACECs can be found in Chapter 4.10, *Protected Open Space and Areas of Critical Environmental Concern*. Information regarding wetland resources within these ACECs, and potential impacts from the project, can be found in the Chapter 4.16, *Wetlands*.

[5] National Wild and Scenic Rivers webpage: http://www.rivers.gov/.

Table 4.17-1 Named Waterbodies Adjacent to or Crossed by Project Alternatives[1]

Waterbody	
Assawompset Pond	Pierce Brook
Cedar Swamp River	Pine Swamp Brook
Beaver Meadow Brook	Prospect Hill Pond
Black Brook	Pocksha Pond
Cedar Swamp River	Quequechan River
Cotley River	Queset Brook
Fall Brook	Rattlesnake Brook
Forge Pond (Canton)	Steep Brook
Long Pond	Taunton River
Mill River	Whitman Brook
New Bedford Inner Harbor	Terry Brook
Forge Pond (Freetown)	Assonet River

1 Waterbodies within 100 feet of the centerline of an alternative are considered adjacent.

The list of waterbodies in Table 4.17-1 includes two ORWs pursuant to the *Massachusetts Surface Water Quality Standards* (314 CMR 4.04): Black Brook (Easton), and Fall Brook (Freetown). Details on the existing quality and regulatory status of the waterbodies identified are provided in Section 4.17.2, *Existing Conditions*.

The Massachusetts Water Quality Standards (314 CMR 4.00) assign class designations to inland and coastal waters. These classes specify water quality standards based on the intended uses of the waterbodies. The standards for each class can address characteristics such as temperature, dissolved oxygen (DO), pH, bacteria, solids, color and turbidity, oil and grease, and taste and odor. The classes for inland waters are:

- Class A waters are designated as sources of public drinking water supply, as excellent fish and wildlife habitat, and for primary and secondary contact recreational activities. The standards for contact recreation must be met for Class A waters even if these activities are not permitted (e.g., in a reservoir). Class A waters also have excellent aesthetic value. This is the most stringent inland water classification and includes strict standards for bacteria, DO, and other characteristics to protect the designated uses of the water and human health.

- Class B waters are designated for primary and secondary contact recreational activities and for fish and wildlife habitat. Class B waters are suitable for compatible industrial processes and cooling, irrigation, and other agricultural uses. Class B waters also have consistently good aesthetic value. Some Class B waters are designated as suitable for public water supply with appropriate treatment.

- Class C waters are designated for secondary contact recreational activities and for fish and wildlife habitat. Class C waters are suitable for compatible industrial processes and cooling and for irrigation of crops that are intended for cooking before consumption. Class C waters also have good aesthetic value. This is the least stringent inland water classification.

The classes for coastal and marine waters are:

- **Class SA** waters are designated for primary and secondary contact recreational activities, and as excellent fish and wildlife habitat. Class SA waters also have excellent aesthetic value. Specific Class SA waters may be designated for shellfish harvesting in 314 CMR 4.00. Any desalination plant making withdrawals from a Class SA water must protect the existing and designated uses of the water. This is the most stringent coastal water classification and includes strict standards for bacteria, DO, and other characteristics to protect the designated uses of the water and human health.

- **Class SB** waters are designated for primary and secondary contact recreational activities and as fish and wildlife habitat. Class SB waters also have consistently good aesthetic value. Specific Class SB waters may be designated for shellfish harvesting in 314 CMR 4.00. Any desalination plant making withdrawals from a Class SB water must protect the existing and designated uses of the water.

- **Class SC** waters are designated for secondary contact recreational activities and as fish and wildlife habitat. Class SC waters are suitable for compatible industrial processes and cooling. Class SC waters also have good aesthetic value.

Most major waterbodies in Massachusetts are classified in 314 CMR 4.00. Waters not specified in the regulations are assumed to be Class B (inland) or Class SA (coastal). However, the regulations specify other ways that classifications can be determined. For example, tributaries to a drinking water supply (which would itself be designated Class A) would be designated as Class A waters in order to protect the intended uses downstream.

In addition to the water classifications in 314 CMR 4.00, MassDEP also maintains the *Massachusetts Integrated List of Waters*, which is updated every two years and provides more detail on individual waterbodies.[6] This list identifies what designated uses are attained, what impairments have been reported, and whether or not a TMDL has been prepared, if required. Waterbodies with ongoing impairments may require a TMDL for a given contaminant. TMDLs identify the major contributors to a given impairment (e.g., sources within a watershed that may contribute to the contamination or impairment) and specifies both general and individual discharge limits that must be met in order to reduce contaminant loading and improve the health of the waterbody. TMDLs are first developed in draft form and must be approved by USEPA in order to be implemented.

To summarize these details, the *Massachusetts Integrated List of Waters* divides waterbodies into various categories:

- **Category 1 Waters**: Waters attaining all designated uses.

- **Category 2 Waters**: Attaining some uses; other uses not assessed.

- **Category 3 Waters**: No uses assessed.

[6] Massachusetts Department of Environmental Protection, Division of Watershed Management. *Massachusetts Year 2006 Integrated List of Waters*. October 2007.

- **Category 4a Waters**: TMDL is completed.
- **Category 4c Waters**: Impairment not caused by a pollutant.
- **Category 5 Waters**: Waters requiring a TMDL.

Waterbodies used for drinking water supply were identified separately from the basic waterbody screening discussed above. Massachusetts Drinking Water Regulations (310 CMR 22.00) define three different Surface Water Supply Protection Zones that surround reservoirs and other surface drinking water sources as follows:

- **Zone A** represents:
  - the land area between the surface water source and the upper boundary of the bank;
  - the land area within 400 feet of the upper boundary of the bank of a Class A surface water source, defined in 314 CMR 4.05(3)(a); and
  - the land area within 200 feet of the upper boundary of the bank of a tributary or associated surface waterbody.
- **Zone B** represents the land area within one-half mile of the upper boundary of the bank of a Class A surface water source, or the edge of the watershed, whichever is less. Zone B always includes the land area within 400 feet of the upper boundary of the bank of a Class A surface water source.
- **Zone C** represents the land area not designated as Zone A or B within the watershed of a Class A surface water source.

The screening process identified three drinking water supplies with Zone A areas that would be crossed by one or more alternatives: the Farm River/Richardi Reservoir system, the Long Pond/Assawompset Pond/Pocksha Pond system, and the Brockton Reservoir (also known as the Avon Reservoir). Details on these water supplies are provided in the section on Surface Water Resources.

Groundwater Resources

Groundwater resource areas are defined and regulated pursuant to the *Massachusetts Drinking Water Regulations*. Many of the municipalities in and along the project alternatives have public drinking water supply wells near the rail corridors.[7] These wells can include municipal supplies as well as any supplies that provide water to at least 15 service connections. Table 4.17-2 lists each town and the number of public water supply wells identified. The number of wells varies greatly between municipalities.

[7] The definition of public water supplies in 310 CMR 22.02 includes any systems that provide at least 15 service connections or regularly serve an average of at least 25 individuals daily at least 60 days of the year.

Table 4.17-2 Public Water Supply Wells by Municipality

Municipality	Public Water Supply Wells	Municipality	Public Water Supply Wells
Berkley	0	Lakeville	7
Canton	6	New Bedford	0
Easton	6	Raynham	14
Fall River	0	Stoughton	12
Freetown	1	Taunton	3

Groundwater resource areas are defined and regulated pursuant to the *Massachusetts Drinking Water Regulations*. The groundwater supply protection areas (310 CMR 22.21) surrounding public water supply wells are described:

- **Zone I:** The protective radius required around a public water supply well or well field. This radius varies in size from 100 to 400 feet based on the approved yield of the well.
- **Zone II:** The area of an aquifer that contributes water to a well under the most severe pumping and recharge conditions that can be realistically anticipated.
- **Zone III:** The area beyond Zone II from which surface water and groundwater drain into the Zone II.
- **Interim Wellhead Protection Area (IWPA):** The primary protected recharge area for public wells without a DEP-approved Zone II. The IWPA radius can range from a minimum of 400 feet to a maximum of 0.5 mile. The default radius is 0.5 mile.

The Groundwater Supply Protection regulations require that Zone I areas be "owned or controlled by the supplier of water" [310 CMR 22.21(1) (b)]. Zoning controls are required to restrict land use within Zone II and Zone III. Track, trains, roads, and parking areas are not prohibited uses in Zone II and Zone III areas.

Aquifers may be designated as Sole Source Aquifers (SSAs) by the USEPA if they provide at least 50 percent of a community's drinking water and there are no reasonable alternative drinking water sources available. Since the contamination of an SSA could leave residents without drinkable water, any projects proposed within an SSA that receive federal funding are subject to review by USEPA to ensure they do not endanger the aquifer. The proposed project alternatives do not cross any SSAs.

Details on the specific wells and protection areas near each alternative are provided in the section on Groundwater Resources.

4.17.2.2 Study Corridor

This section describes the existing conditions of surface water resources and public water supply wells that could be affected by the alternatives and identifies the specific resources that could be affected under each alternative. Figure 4.17-1 shows the project area and major waterbodies. Figure 1.4-1 illustrates the alternative alignments and associated station locations, in relation to these waterbodies.

Surface Water Resources

The classes and categories identified by MassDEP in the *Massachusetts Integrated List of Waters* and the *Massachusetts Water Quality Standards* (discussed in Section 4.17.2.1, *Regional Overview*) provide an effective summary of a waterbody's uses and overall health. Table 4.17-3 lists these and other relevant information for the waterbodies adjacent to the project. With one exception, these waterbodies are Class B or SB waters, indicating that they should be safe for recreational use and provide good fish and wildlife habitat but do not need to meet drinking water standards. The Wading River is considered a Class A water upstream of the Wading River Pumping Station in Mansfield and a Class B water downstream.

Table 4.17-3 Streams and Ponds Classified by MassDEP

Waterbody	Category	Class	ORW	Uses Attained	Impairments	TMDLs
Assonet River	2 and 5	B	No	Aquatic life, primary and secondary contact, aesthetics	Pathogens	
Beaver Meadow Brook	5	B	No		Organic enrichment/low DO, pathogens	Pathogens[1]
Cedar Swamp River	2	B	No	Aquatic life, primary and secondary contact, aesthetics		
Cotley River	3	B	No			
Forge Pond (Canton)	3	B	No			
Mill River	3	B	No			
New Bedford Inner Harbor	5	SB	No		Priority organics,- metals, nutrients, organic enrichment/low DO, pathogens, oil and grease, taste, odor and color, objectionable deposits	
Prospect Hill Pond	3	B	No			
Quequechan River	4c	B	No		Habitat alterations	
Queset Brook	3	B	No			
Rattlesnake Brook	2	B	No	Aquatic life, aesthetics		
Taunton River	5	B/SB[2]	No		Pathogens, organic enrichment/ low DO, additional unknown causes	Pathogens (draft)

1 Beaver Meadow Brook is covered by the pathogen TMDL for the Neponset River.

2 The Taunton River is considered a coastal water downstream of Route 24, where it is classified SB.

Not all of the streams identified in the screening process have been included in MassDEP assessments to date. Table 4.17-4 lists the named streams identified in the screening process that have not been

assessed by MassDEP in the *Massachusetts Integrated List of Waters* and were not assigned classes in 314 CMR 4.00. Most of these streams are assumed to be Class B waters (based on 314 CMR 4.00) and have no known TMDLs or impairments. However, Fall Brook is tributary to Long Pond in Lakeville and Freetown, which is a public drinking water supply. Therefore, Fall Brook is a Class A water as it is tributary to a drinking water supply.

Table 4.17-4 Named Streams and Ponds Not Assessed by MassDEP

Waterbody	Class	ORW
Black Brook	B	Yes
Fall Brook	A	Yes
Pierce Brook	B	No
Pine Swamp Brook	B	No
Steep Brook	B	No
Whitman Brook	B	No

There are three separate surface drinking water supplies that have protection zones crossed by or adjacent to the project alternatives. Table 4.17-5 lists the waterbodies that make up these water supplies.

Table 4.17-5 Surface Drinking Water Supplies

Waterbody	Category	Class	ORW	Impairments	Users	Relevant Tributaries[1]
Assawompset Pond	3	A	Yes		New Bedford, Taunton	Fall Brook
Long Pond	4c	A	Yes	Exotic species		
Pocksha Pond	3	A	Yes			

1 These are tributaries that are adjacent to the proposed project alternatives.

Further details on the resources that are in proximity to each specific alternative are provided below.

Southern Triangle Study Area (Common to All Build Alternatives)

The "Southern Triangle" portion of the project (Figures 4.17-2a-e and 4.17-3a-c) requires the railbed, track, and signals along the existing Fall River Secondary and New Bedford Main Lines to be upgraded for passenger rail traffic. This portion of the project extends from Weir Junction in Taunton along the New Bedford Main Line through Berkley, Lakeville, Freetown and New Bedford and along the Fall River Secondary from Myricks Junction in Lakeville through Freetown and Fall River. The Southern Triangle would cross or run adjacent to 10 waterbodies, listed in Table 4.17-6. The Southern Triangle also crosses the Zone A areas for Long Pond, Assawompset Pond, and Pocksha Pond, which provide drinking water for the cities of New Bedford and Taunton.

Table 4.17-6 Named Waterbodies Adjacent to or Crossed By the Southern Triangle

Waterbody	Municipality	Rail Segment	Relationship
Taunton River	Taunton	New Bedford Main Line	Crossed by bridge
Assawompset Pond	Freetown, Lakeville	New Bedford Main Line	Zone A crossed by alternative
Assonet River	Lakeville	Fall River Secondary	Within 100 feet of alternative
Cedar Swamp River	Lakeville	Fall River Secondary, New Bedford Main Line	Crossed by bridge
Cotley River	Berkley	New Bedford Main Line	Within 100 feet of alternative
Fall Brook	Freetown	New Bedford Main Line	Crossed by bridge
Forge Pond (Freetown)[1]	Freetown	Fall River Secondary	Within 100 feet of alternative
Long Pond	Freetown, Lakeville	New Bedford Main Line	Zone A crossed by alternative
New Bedford Inner Harbor	New Bedford	Fall River Secondary, New Bedford Main Line	Within 100 feet of alternative
Pierce Brook	Lakeville	New Bedford Main Line	Crossed by bridge
Pocksha Pond	Freetown, Lakeville	New Bedford Main Line	Zone A crossed by alternative
Quequechan River	Fall River	Fall River Secondary	Crossed by bridge
Rattlesnake Brook	Freetown	Fall River Secondary	Crossed by bridge
Steep Brook	Fall River	Fall River Secondary	Crossed by bridge

1 This Forge Pond is separate and distinct from the Forge Pond in Canton.

Taunton River—The Taunton River is a major river that extends from the confluence of the Town River and Matfield River in Bridgewater to Mount Hope Bay. The river has a roughly 562 square mile watershed that includes parts of 40 different municipalities and 94 square miles of wetlands. The river has been designated as a Wild and Scenic River by the National Park Service. This designation requires specific review by the Corps for any alteration of flows to the river or its tributaries, as well as the protection of the river's viewsheds and any historic or scenic structures associated with the river.

The Taunton River is a Class B waterbody, indicating that it is not suitable for untreated drinking water supply but should be suitable for primary and secondary contact recreation and provide good fish and wildlife habitat. The Taunton River is considered a coastal water downstream of the Route 24 bridge, where its classification changes from Class B to Class SB. The Taunton River is designated by MA DEP as impaired due to excess bacteria (pathogens), excess organic enrichment/low DO, and additional unspecified impairments. A draft TMDL for bacteria has been proposed for the Taunton River. The TMDL will not take effect until it is approved by the USEPA. Meeting this TMDL will require substantial reductions in bacteria loading from municipal stormwater runoff, leaking sanitary sewer lines, and combined sewer overflows (CSOs). Limitations have also been proposed for wastewater treatment discharges to the Taunton River and its tributaries.

The Taunton River is crossed several times on existing bridges just north of Weir Junction along the Stoughton Line and again just south of Weir Junction along the New Bedford Main Line.

Assawompset Pond, Long Pond, and Pocksha Pond—The Southern Triangle is not adjacent to Assawompset Pond, Long Pond, or Pocksha Pond, but it crosses the Zone A areas for all three in Freetown and Lakeville (4.17-2c). Long Pond is contiguous with Assawompset Pond and Pocksha Pond,

and they operate as a single waterbody. Together with Great Quittacas Pond, Little Quittacas Pond, and Elders Pond, these lakes provide drinking water for the cities of Taunton and New Bedford. Assawompset Pond was dammed at the Nemasket River in 1894, increasing the overall depth by approximately five feet. As a drinking water supply, the ponds are designated as Class A waterbodies and as ORWs. Long Pond is a Category 4c water and is listed as impaired due to exotic species. Assawompset Pond and Pocksha Pond are Category 3 waters, indicating that their intended uses have not been assessed by MassDEP.

Assonet River—The Assonet River (Figure 4.17-3a) is a tributary of the Taunton River and includes Assonet Bay, an inland waterbody with branches to the north, east, and south. The Assonet River continues east from Assonet Bay. The river is controlled by dams at Mill Street and at Forge Road in Assonet and continues upstream to Lakeville, where it becomes the Cedar Swamp River. The Assonet River is a Class B surface water, indicating that it should have consistently good aesthetic and habitat values, is intended for primary and secondary contact recreation, and is not intended for drinking water supply without treatment beforehand. The Assonet River is listed as both a Category 2 water and a Category 5 water, indicating that it meets some of its assessed uses but is also in need of a TMDL. The Assonet River is considered to attain its intended uses for aquatic life, primary and secondary contact recreation, and aesthetics, but it is also impaired due to excess pathogens, which requires a TMDL.

Cedar Swamp River—As discussed above, the Cedar Swamp River (Figure 4.17-2b) is an upstream continuation of the Assonet River and is therefore tributary to the Taunton River. The swamp surrounding the Cedar Swamp River is protected as part of the Assonet Cedar Swamp Wildlife Sanctuary. Like the Assonet River, the Cedar Swamp River is a Class B surface water, indicating that it should have consistently good aesthetic and habitat values, is intended for primary and secondary contact recreation, and is not intended for drinking water supply without treatment beforehand. The Cedar Swamp River is a Category 2 surface water and attains its intended uses for aquatic life, primary and secondary contact recreation, and aesthetics.

Cotley River—The Cotley River (Figure 4.17-2a) is a tributary of the Taunton River and runs through Barstows Pond to the Taunton River. The Cotley River is a Class B surface water, indicating that it should have consistently good aesthetic and habitat values, is intended for primary and secondary contact recreation, and is not intended for drinking water supply without treatment beforehand. The Cotley River is a Category 3 surface water, indicating that its intended uses have not been assessed by MassDEP.

Forge Pond (Freetown)—Forge Pond is located in Freetown (Figure 4.17-3a) and should not be confused with the Forge Pond located in Canton. Forge Pond is a Class B surface water, indicating that it should have consistently good aesthetic and habitat values, is intended for primary and secondary contact recreation, and is not intended for drinking water supply without treatment beforehand. Forge Pond is a Category 3 surface water, indicating that its intended uses have not been assessed by MassDEP.

New Bedford Inner Harbor—New Bedford Inner Harbor (Figure 4.17-2e) is the estuary of the Acushnet River, where the river flows into Buzzards Bay. The inner harbor is guarded by a hurricane barrier that protects boats in the harbor from severe storms. New Bedford Inner Harbor is a Class SB surface water, indicating that it should have consistently good aesthetic value and is intended for primary and secondary contact recreational activities and fish and wildlife habitat. The harbor is a Category 5 surface water and requires TMDLs to address impairments from priority organics, metals, nutrients, organic enrichment/low DO, pathogens, oil and grease, taste, odor and color, and objectionable deposits.

Quequechan River—The Quequechan River (Figure 4.17-3c) is a tributary of the Taunton River and runs from South Watuppa Pond to Battleship Cove on the Taunton River. The Quequechan River is a Class B surface water, indicating that it should have good aesthetic and habitat values, is intended for primary and secondary contact recreation, and is not intended for drinking water supply without treatment beforehand. The river is also a Category 4c surface water, indicating that it is impaired but that the impairment is not due to a contaminant. In this case, the river is impaired due to channelization of portions of the river, impacting its function as wildlife habitat.

Rattlesnake Brook—Rattlesnake Brook (Figure 4.17-3b) is a tributary of the Taunton River and runs through the Freetown-Fall River State Forest. The brook is a Class B surface water, indicating that it should have consistently good aesthetic and habitat values, is intended for primary and secondary contact recreation, and is not intended for drinking water supply without treatment beforehand. Rattlesnake Brook is a Category 2 surface water and attains its intended uses for aquatic life and aesthetics.

Unlisted Waterbodies—Fall Brook (Figure 4.17-2c), Pierce Brook (Figure 4.17-2b) and Steep Brook (Figure 4.17-3b) are all crossed by the Southern Triangle but have not been included on the *Massachusetts Integrated List of Waters* by MassDEP.

Fall Brook is a tributary of Long Pond, which is contiguous with Assawompset Pond and Pocksha Pond. These ponds are part of the surface drinking water supply for New Bedford and Taunton. Therefore, Fall Brook is a Class A surface water, indicating that it is designated as a public drinking water supply (or is tributary to one) and should provide excellent fish and wildlife habitat, support primary and secondary contact recreational activities, and have excellent aesthetic value. Fall Brook is also an ORW, and the area within 400 feet of the brook is designated as Zone A.

Pierce Brook is a Class B surface water, indicating that it should have consistently good aesthetic and habitat values, is intended for primary and secondary contact recreation, and is not intended for drinking water supply without treatment beforehand. The brook is located north of the Cedar Swamp River in the Assonet Cedar Swamp.

Steep Brook is a Class B surface water, indicating that it should have consistently good aesthetic and habitat values, is intended for primary and secondary contact recreation, and is not intended for drinking water supply without treatment beforehand.

Stoughton Alternative Study Area

The Stoughton Electric and Diesel Alternatives (Figures 4.17-4a through e) would provide commuter rail service through Stoughton, extending the existing Stoughton Line service. From Weir Junction in Taunton, trains would use the New Bedford and Fall River lines to reach the terminal stations. In addition to the 10 named waterbodies crossed by or adjacent to the Southern Triangle, the Stoughton Alternative (Electric and Diesel) would cross or run adjacent to eight named waterbodies. Table 4.17-7 lists the waterbodies unique to this alternative.

Information on the Taunton River is provided above. Other named waterbodies crossed by or adjacent to the Stoughton Alternative are discussed below.

Table 4.17-7 Named Waterbodies Adjacent to or Crossed By the Stoughton Alternative

Waterbody	Municipality	Rail Segment	Relationship
Beaver Meadow Brook	Canton	Stoughton Line	Crossed by bridge
Black Brook	Easton	Stoughton Line	Crossed by bridge
Forge Pond (Canton)[1]	Canton	Stoughton Line	Crossed by bridge
Mill River	Taunton	Stoughton Line	Crossed by bridge
Pine Swamp Brook	Raynham	Stoughton Line	Within 100 feet of alternative
Queset Brook	Easton	Stoughton Line	Crossed by bridge
Taunton River	Taunton	Stoughton Line	Crossed by bridge in
Whitman Brook	Easton, Stoughton	Stoughton Line	Crossed by bridge

Note: This table does not include waterbodies that are adjacent to or crossed by the Southern Triangle, listed in Table 4.17-6.
1 This Forge Pond is separate and distinct from the Forge Pond in Freetown that is crossed by the Southern Triangle.

Beaver Meadow Brook—Beaver Meadow Brook (Figure 4.17-4a) flows from Glen Echo Pond in Stoughton to Bolivar Pond in Canton. The brook is a Class B surface water, indicating that it should have consistently good aesthetic and habitat values, is intended for primary and secondary contact recreation, and is not intended for drinking water supply without treatment beforehand. Beaver Meadow Brook is a Category 5 surface water and requires a TMDL to address organic enrichment/low DO. The brook is also impaired due to pathogens, which is covered by the bacteria TMDL for the Neponset River.

Forge Pond (Canton)—Forge Pond (Figure 4.17-4a) is located in Canton (not to be confused with the Forge Pond located in Freetown that is crossed by the Southern Triangle). Forge Pond is a Class B surface water, indicating that it should have consistently good aesthetic and habitat values, is intended for primary and secondary contact recreation, and is not intended for drinking water supply without treatment beforehand. Forge Pond is a Category 3 surface water, indicating that its intended uses have not been assessed by MassDEP.

Mill River—The Mill River (Figure 4.17-4e) is located in Taunton and is a tributary of the Taunton River. The river runs from Lake Sabbatia through the City of Taunton to its confluence with the Taunton River. The Mill River is a Class B surface water, indicating that it should have consistently good aesthetic and habitat values, is intended for primary and secondary contact recreation, and is not intended for drinking water supply without treatment beforehand. The Mill River is a Category 3 surface water, indicating that its intended uses have not been assessed by MassDEP.

Queset Brook—Queset Brook (Figure 4.17-4b) is located in Easton and is a tributary of the Taunton River. The brook is a Class B surface water, indicating that it should have consistently good aesthetic and habitat values, is intended for primary and secondary contact recreation, and is not intended for drinking water supply without treatment beforehand. Queset Brook is a Category 3 surface water, indicating that its intended uses have not been assessed by MassDEP.

Unlisted Waterbodies—Black Brook (Figure 4.17-4c), Pine Swamp Brook (Figure 4.17-4d), and Whitman Brook (Figure 4.17-4b) are all crossed by The Stoughton Alternative (Electric and Diesel) but have not been included on the *Massachusetts Integrated List of Waters* by MassDEP.

Black Brook is located in Easton. The brook is a Class B surface water, indicating that it should have consistently good aesthetic and habitat values, is intended for primary and secondary contact recreation, and is not intended for drinking water supply without treatment beforehand.

Pine Swamp Brook is located in Raynham and runs from Prospect Hill Pond to the Taunton River. The brook is a Class B surface water, indicating that it should have consistently good aesthetic and habitat values, is intended for primary and secondary contact recreation, and is not intended for drinking water supply without treatment beforehand.

Whitman Brook is located in Stoughton and Easton. The brook is a Class B surface water, indicating that it should have consistently good aesthetic and habitat values, is intended for primary and secondary contact recreation, and is not intended for drinking water supply without treatment beforehand.

Whittenton Alternative Study Area

The Whittenton Alternative (Figures 4.17-4a-d and 4.17-5a-b) would avoid construction through the Pine Swamp. This would include restoration of the track system from the New Bedford Main Line up to Weir Junction in Taunton, and then connect to the Stoughton Line through the Whittenton Branch. In addition to the 10 named waterbodies crossed by or adjacent to the Southern Triangle, The Whittenton Alternative would cross or run adjacent to nine named waterbodies. Table 4.17-8 lists the waterbodies unique to this alternative. Information on Beaver Meadow Brook, Black Brook, Forge Pond, the Mill River, Pine Swamp Brook, Queset Brook, and Whitman Brook is presented above. Prospect Hill Pond is discussed below.

Table 4.17-8 Named Waterbodies Adjacent to or Crossed by the Whittenton Alternative

Waterbody	Municipality	Rail Segment	Relationship
Beaver Meadow Brook	Canton	Stoughton Line	Crossed by bridge
Black Brook	Easton	Stoughton Line	Crossed by bridge
Forge Pond (Canton)[1]	Canton	Stoughton Line	Crossed by bridge
Mill River	Taunton	Stoughton Line, Whittenton Branch	Crossed by bridge
Pine Swamp Brook	Raynham	Stoughton Line	Within 100 feet of alternative
Prospect Hill Pond	Taunton	Whittenton Branch	Within 100 feet of alternative
Queset Brook	Easton	Stoughton Line	Crossed by bridge
Whitman Brook	Easton, Stoughton	Stoughton Line	Crossed by bridge

Note: This table does not include waterbodies that are adjacent to or crossed by the Southern Triangle, listed in Table 4.17-6.
1 This Forge Pond is separate and distinct from the Forge Pond in Freetown that is crossed by the Southern Triangle.

Prospect Hill Pond—Prospect Hill Pond (Figure 4.17-5a) is located in Taunton and is the source of Pine Swamp Brook. The pond is a Class B surface water, indicating that it should have consistently good aesthetic and habitat values, is intended for primary and secondary contact recreation, and is not intended for drinking water supply without treatment beforehand. Prospect Hill Pond is a Category 3 surface water, indicating that its intended uses have not been assessed by MassDEP.

Station Sites

Twelve stations would be modified or constructed as part of the South Coast Rail project. Modifications are proposed at two existing stations (Canton Center and Stoughton). The modifications at the existing

Canton Center Station are limited to the construction of a new Americans with Disabilities Act- (ADA) compliant platform and canopy and do not involve the construction of additional impervious area. The existing Stoughton Station would be removed and replaced with a new station at a different location. New platform-only stations would be constructed at four sites: Easton Village, King's Highway, Whale's Tooth, and Battleship Cove. These are developed sites with existing parking facilities (King's Highway and Whale's Tooth) or are drop-off facilities without on-site parking (Easton Village and Battleship Cove). One station, at Fall River Depot, would be constructed on the site of the former railroad station and would include a structured parking facility that would maintain existing drainage patterns at the site.

Five new stations would be constructed that would discharge stormwater runoff to wetlands and would require compliance with the Stormwater Standards. Two of these stations (Taunton and Raynham Park) are located on previously developed sites. Three stations (North Easton, Taunton Depot, and Freetown) would be located on currently undeveloped sites.

None of the station sites contain surface water resources. However, many of the station sites are adjacent to waterbodies.

- The Battleship Cove, Taunton Depot, Freetown, Taunton, Raynham Park, and Freetown station sites are all within 100 feet of unnamed waterbodies. The Easton Village site is adjacent to Queset Brook, described above.

Layover Facility Study Areas

Two new overnight layover facilities are proposed as part of the South Coast Rail project. These facilities are proposed near the southern terminus of the New Bedford Main Line (Wamsutta) and the southern terminus of the Fall River Secondary (Weaver's Cove East). The facilities are necessary to provide locations for train sets to be stored overnight, for train crews to board the train at the start of each shift, and for minor maintenance activities to be performed to the trains.

- The Weaver's Cove East Layover Facility is located approximately 2.5 miles from the southern terminus of the Fall River Secondary line, between Main Street and the Secondary. The Wamsutta Layover Facility is located along the New Bedford Main Line, near the intersection of Wamsutta Street and Herman Melville Boulevard.

There are no source water resources located within the proposed layover facility options. However, the Taunton River is located approximately 100 feet from the Weaver's Cove East Facility. The Acushnet River is located approximately 400 feet from the Wamsutta Layover Facility site.

Groundwater Resources

The proposed alternatives have the potential to affect distinct public groundwater suppliers in the project area. These water suppliers were identified based on the Zone I and Zone II areas that would either be crossed by or within 100 feet of one or more alternatives. Table 4.17-9 lists the water suppliers that could be affected by the project and provides details on the extent and capacity of these water systems.

Table 4.17-9 Public Groundwater Supplies with Protection Zones Adjacent to or Crossed by the Alternatives

Water Supplier	Number of Wells	Wells with Potential Protection Zone Crossings	Typical System Pumping Rate (gallons per day)	Other Water Sources
Easton Water Division	6 wells	5 + 1 proposed	2 million	
North Raynham Water District	4 wells, 1 proposed well field,[1] 1 proposed well	5 + 2 proposed	340,000	Raynham is also served by the Raynham Center Water District.

1 Wellfields usually consist of multiple small-diameter wells pumped simultaneously.

This section discusses the groundwater protection zones that are crossed by or adjacent to the proposed project alternatives.

Southern Triangle Study Area (Common to All Build Alternatives)

The Southern Triangle would intersect the IWPAs for both of the wells operated by the Freetown-Lakeville Regional School District in Lakeville (Figure 4.17-2c). The wells themselves are located approximately half a mile east of the New Bedford Main Line.

Stoughton Alternative Study Area (Electric and Diesel)

In addition to the IWPA crossed by the Southern Triangle, the Stoughton Alternative (Electric and Diesel) would intersect Zone II areas for six wells, listed in Table 4.17-10.

Table 4.17-10 Public Water Supply Wells with Protection Areas Adjacent to or Crossed by the Stoughton Alternative (Electric and Diesel)

Well	Water System	Location of Well	Protection Zones within 100 feet of Project Area	Location of Protection Zone Crossings
Easton GP Well #1	Easton Water Division	Easton	Zone II	Easton, Stoughton
Easton GP Well #2		Easton	Zone II	Easton, Stoughton
Easton GP Well #4		Easton	Zone II	Easton, Stoughton
King Philip St. Well #3A	North Raynham Water District	Raynham	Zone II	Raynham
King Philip St. Well #3B		Raynham	Zone II	Raynham
King Philip Bedrock Well[1]		Raynham	Zone II	Raynham

Note: This table does not include the IWPA crossed by the Southern Triangle.
1 Proposed well

The Stoughton Alternative would intersect the Zone II for Easton GP Wells #1, #2, and #4, (Figure 4.17-4c), which are three of the six wells providing drinking water to the Town of Easton. Easton GP Well #1 is approximately 500 feet to the east of the Stoughton Line and is the well closest to this alternative. The Zone I for Easton GP Well #1 has a 400-foot radius, which is close to the alternative.

The alternative would also intersect the Zone II areas in Raynham for King Philip Street Wells #3A and #3B as well as the proposed King Philip Bedrock Well (Figure 4.17-4d). King Philip Street Wells #3A and #3b are approximately 1,800 feet east of the Stoughton Line. Although the King Philip Bedrock Well has

not been put into service, the surrounding area is protected in order to ensure that the aquifer will remain usable when the well is constructed.

Whittenton Alternative

In addition to the IWPA crossed by the Southern Triangle, the Whittenton Alternative would intersect Zone II areas for 10 existing or proposed wells and one Zone I area. Table 4.17-11 lists the wells with protection zones crossed by this alternative.

The Whittenton Alternative would cross the protection zones for all six of the North Raynham Water District's wells, including the Zone I for King Philip Street Well #2 (Figure 4.17-5a). King Philip Street Well #2 is within 200 feet of the Whittenton Branch, and the Zone I area for the well has a 400-foot radius. The Whittenton Alternative would cross the Zone II areas for King Philip Street Wells #1, #2, #3A, and #3B, the First Street Replacement Well, and the proposed Noblin Wellfield. King Philip Street Well #1 is near King Philip Street Well #2 and is approximately 900 feet southeast of the Whittenton Branch. The First Street Replacement Well (Figure 4.17-5d) is located between the Stoughton Line and the Whittenton Branch. The proposed Noblin Wellfield has not been constructed but will be located east of the Whittenton Branch on the far side of Prospect Hill Pond.

Table 4.17-11 Public Water Supply Wells with Protection Areas Adjacent to or Crossed by the Whittenton Alternative

Well	Water System	Location of Well	Protection Zones within 100 feet of Project Area	Location of Protection Zone Crossings
Easton GP Well #1	Easton Water Division	Easton	Zone II	Easton, Stoughton
Easton GP Well #2		Easton	Zone II	Easton, Stoughton
Easton GP Well #4		Easton	Zone II	Easton, Stoughton
Noblin Well Field[1]	North Raynham Water District	Raynham	Zone II	Raynham, Taunton
First St. Replacement Well		Raynham	Zone II	Raynham, Taunton
King Philip St. Well #1		Raynham	Zone II	Raynham, Taunton
King Philip St. Well #2		Raynham	Zone I and Zone II	Raynham, Taunton
King Philip St. Well #3A		Raynham	Zone II	Raynham
King Philip St. Well #3B		Raynham	Zone II	Raynham
King Philip Bedrock Well[1]		Raynham	Zone II	Raynham

Note: This table does not include the IWPA crossed by the Southern Triangle.
1 Proposed well

The Whittenton Alternative would intersect the Zone II for Easton GP Wells #1, #2, and #4, (Figure 4.17-4c) and would be close to the Zone I for Easton GP Well #1, already discussed above.

Station Sites

None of the station sites intersect any Zone I areas. The Easton Village and North Easton sites are within the Zone II for Easton GP Wells #1, #2, and #4.

Layover Facility Sites

None of the proposed layover facility sites are located within groundwater resource areas, particularly drinking water protection areas.

Summary

This section documents and describes the surface waterbodies and public surface and groundwater supply protection areas that are crossed by or in proximity to the Southern Triangle (common to all Build Alternatives), and the portions of the Build Alternatives that are north of Weir Junction in Taunton.

All Build Alternatives cross or are adjacent to surface waters and public water supply protection areas. Table 4.17-12 summarizes the resources that are crossed by or adjacent to each alternative.

Table 4.17-12 Summary of Water Resources Crossed By or Adjacent to Each Alternative[1]

Alternative or Element	Named Waterbodies	Public Water Supplies With Protection Areas Crossed by or Adjacent to Each Alternative: Zone A Areas[2]	Zone I Areas[3]	Zone II Areas[3]	IWPAs[3]
Southern Triangle	14	1	0	0	2
Stoughton	8	0	0	6	0
Whittenton	8	0	1	10	0
Layover Facilities	2	0	0	0	0

1 Based on waterbodies and water supply protection areas within 100 feet of the project area.
2 Surface water supplies that consist of connected waterbodies, such as a reservoir with a tributary, are treated here as a single supply and single Zone A.
3 Proposed construction within 400 feet. Each existing or proposed groundwater well is treated as a separate public water supply.

4.17.3 Analysis of Impacts and Mitigation

4.17.3.1 Introduction

This section identifies the impacts to water resources that may result from implementing each of the South Coast Rail alternatives under consideration (including railroad or highway alignments, train stations, and layover facilities).

Surface and groundwater resources are protected under several state and federal regulatory programs, including the federal Clean Water Act and the Massachusetts Clean Waters Act (MGL Chapter 21, §26-53). Other applicable regulations include the Massachusetts Discharge Regulations (314 CMR 9.00), Groundwater Quality Standards (314 CMR 6.00), Surface Water Quality Standards (314 CMR 4.00), and Wetland Protection Regulations (310 CMR 10.00). The Massachusetts Department of Environmental Protection (MassDEP) is in the process of adopting new stormwater regulations (314 CMR 21.00) that would require specific forms of stormwater management for projects above a certain size or projects located in watersheds with designated total maximum daily loads (TMDLs) for one or more pollutants. Some waterways are also regulated under MGL Chapter 91, which protects the public interest in tidelands, Great Ponds, and non-tidal rivers. More detail on compliance with regulations protecting coastal resources is provided in the Chapter 4.18, *Coastal Zone Consistency and Chapter 91 Compliance*. Impacts to floodplains are discussed in Chapter 4.16, *Wetlands.*

Prior to publication of the DEIS/DEIR, the Secretary's Certificate on the ENF for the South Coast Rail project included a number of requirements for water resources analysis that are addressed in this section. These requirements include:

- Include cumulative totals for land alteration and impervious area.
- Identify any discharges to ORW and provide supporting documentation if a variance pursuant to 310 CMR 4.00 is required.
- Analyze potential impacts to public and private water supplies (both existing and proposed) during the construction and operation of the project and propose avoidance, minimization, and mitigation measures to address impacts.
- Consult with MWRA regarding any potential impacts to MWRA properties or easements.[8]
- Evaluate potential stormwater impacts from construction and operation of the project and demonstrate compliance with stormwater regulations, including the proposed statewide stormwater regulations (314 CMR 21.00). This evaluation should include the rail tracks as well as station sites and layover facilities and should address potential impacts from oil, lubricants, and herbicides. Include plans for stormwater management and details on proposed low impact development (LID) techniques.
- Consult with MassDEP on proposed stormwater management design and construction—related stormwater issues, especially for any discharges to Zone I areas, Zone A areas, or ORWs.
- Existing culverted streams in the right-of-way, as relevant, should be analyzed for upstream and downstream effects under flooding conditions such as the 100-year storm.
- Provide detailed information on waterways that may be impacted by the project, and assess potential impacts to tidal and inland waterways.
- Include streams along Attleboro Secondary in the impact analysis.
- Address compliance with 310 CMR 9.32(2) by avoiding, minimizing, and mitigating any encroachment into a waterway within an ACEC. Other applicable standards include preserving public rights in waterways and providing open space for recreation at or near the water's edge.

Requirements in the Secretary's Certificate related to culverts, stream crossings, and wetland resources are addressed in the Chapter 4.16, *Wetlands.* Requirements regarding tidelands, coastal resources, Chapter 91 jurisdiction, and performance standards for water-dependent structures and uses requiring Chapter 91 authorization are addressed in the Chapter 4.18, *Coastal Zone Consistency and Chapter 91 Compliance*. Comments from MassDEP on the Expanded Environmental Notification Form (EENF) raised concerns about meeting existing and proposed Massachusetts Stormwater Management Standards requirements, using the MBTA's recent Greenbush Line project as an example, with particular focus on drinking water protection. Comments from the North Raynham Water District raised concerns about drinking water wells in Raynham, which have groundwater protection areas that are crossed by the Stoughton and Whittenton Alternatives. These concerns are addressed in this section.

[8] None of the alternatives assessed in this chapter would affect any known MWRA properties or easements.

The Secretary's Certificate on the DEIS/DEIR included the following specific requirements:

- "The FEIR should describe how the project will comply with the Massachusetts Stormwater Standards for work proposed in wetland resource areas and buffer zones pursuant to 310 CMR 10.05(6)(k) and 314 CMR 9.06(6), as well as other state and federal requirements (including total Maximum Daily Load (TMDL) requirements) for stormwater discharges to existing outfall and/or for the proposed layover facilities. The FEIR should describe measures to ensure that stormwater discharges to the Neponset River will meet the TMDL pathogen removal requirements and Total Suspended Soils (TSS) removal requirements."

- "The FEIR should include an assessment of the ability of the proposed project to meet the ten Massachusetts Stormwater Standards or specify if a variance to the Stormwater Standards specified at 310 CMR 10.05(6)(k) and 314 CMR 9.06(6) may be required. For those components of the project where complete raze of existing development is proposed, MassDOT should be fully meeting the Stormwater Standards rather than only "to the extent possible'' as few constraints exist in such situations."

- "The FEIR should include a detailed evaluation of Environmentally Sensitive Site Design (ESSD) and Low Impact Development (LID) practices to manage stormwater at proposed stations and parking areas, and layover facilities. The FEIR should identify the design capacity for parking at each station. Deck parking should be evaluated as an alternative to at-grade parking to minimize the project's impervious footprint and reduce the amount of land taking required. The ESSD and LID alternatives analysis in the FEIR should also include evaluation of smaller parking stalls and circulation lanes; porous pavement; pavement disconnection versus traditional curb and gutter drainage; retention of existing mature non-invasive plants; exfiltrating bioretention in place of raised traffic islands; and tree box filters. The FEIR should clearly identify the ESSD and LID measures to which the Proponent is committed to implement. For those measures not being committed to, the FEIR should include a sound rationale as to why they are not feasible."

- "The FEIR should include information on stormwater peak runoff rates and whether attenuation requirements will be met. The FEIR should assess each station and layover site to determine if there is sufficient land available for attenuation structures or if any additional right-of-way purchase would be required. For those stations being upgraded, the FEIR should include an analysis and description of measures to meet stormwater standards to the Maximum Extent Practicable (MEP) and to improve existing conditions, The FEIR should include an analysis of potential stormwater impacts to critical areas including vernal pools, and how these impacts will be addressed."

- "The FEIR should include details on proposed stormwater management along the proposed rail tracks. As noted in MADEP's comment letter, the Greenbush rail line included an extensive drainage system. The FEIR should describe the proposed drainage design for the Stoughton rail line and demonstrate that sufficient treatment will be provided prior to any discharge of track drainage runoff to resource areas. The FEIR should include a detailed description of the proposed stormwater management system for all components of the project. [MEPA] refers MassDOT to additional guidance regarding stormwater management in MADEP's comment letter."

Additional comments received on the DEIS/DEIR included the following:

Other comments on the DEIS/DEIR related to stormwater and water resources topics were provided by federal and state governmental agencies and other interested parties.

The Massachusetts Department of Environmental Protection (MADEP) submitted the following comments on the DEIS/DEIR:

- Provide information on the ability of the selected alternative to meet each of the 10 Massachusetts Stormwater Standards or specify if a variance to the Stormwater Standards specified at 310 CMR 10.05(6)(k) and 314 CMR 9.06(6) may be required.

- Provide alternatives analysis of Environmentally Sensitive Site Design (ESSD) and Low Impact Development (LID) practices to manage stormwater runoff at proposed stations and parking facilities, such as deck parking, smaller parking stalls and circulation lanes than traditional parking lots, use of porous pavements.

- Provide conceptual design examples of a new station, a reconstructed station, and a section of track in an environmentally sensitive area demonstrating how those structures would be constructed and operated consistent with ESSD and LID concepts.

- Provide information regarding whether stormwater peak runoff rate attenuation requirements will be met and if land-intensive peak rate control structures are needed, whether each station and layover facility contains sufficient land area and whether additional rights-of-way need to be purchased along potential rail line routes to place attenuation structures.

- Provide an analysis of stormwater recharge for its potential to attenuate peak runoff rates and where it cannot be met; describe the use of open attenuation structures over closed structures.

- Identify the design capacity of the parking proposed at each station. For stations with parking lots for 1,000 vehicle trips or more describe additional measures for source control and pretreatment (e.g. porous asphalt), as such parking lots are classified as Land Uses with Higher Potential Pollutant Loads (LUHPPL) and require pre-treatment specified at 310 CMR 10.05(6)(k)(5).

- Describe how each alternative would impact public drinking water sources, vernal pools and other critical areas pursuant to 310 CMR 10.05(6)(k)(6) and how each alternative's stormwater requirements will be addressed so as not to conflict with such critical areas.

- Describe how (in addition to point source stormwater runoff) controls, the alternatives will include source-control measures to minimize potential for contaminants and treatment for areas involving more than 1 acre of land disturbance, which is classified as a point source by USEPA for purposes of the Construction General Permit.

- Provide a description of how compliance with the Massachusetts Stormwater Standards will be achieved for work proposed in wetland resource areas and buffer zones pursuant to310 CMR 10.05(6) (k) and 314 CMR 9.06(6), as well as other state and federal requirements

(including Total Maximum Daily Load (TMDL) requirements) for stormwater discharges to existing outfalls and/or for the proposed layover facilities.

- For those components of the project where complete raze of existing development is proposed, demonstrate how the Stormwater Standards would be fully met rather than only "to the extent possible" as few constraints existing in such situations.

Other comments on the DEIS/DEIR related to water quality:

- Provide additional analysis of impacts on drinking water supply, especially for rail intersections with Zone IIs.
- Clarify the potential for contaminants (spills, drips, or exhaust) associated with rail operations to impact water quality in consideration of water quality data in the vicinity of active rail lines versus water quality data for comparable water resources not near an active rail line, as applicable and identify measures to minimize such impacts on water resources.
- Describe how nitrogen deposition in coastal embayments will be addressed more explicitly.
- Provide an analysis of potential environmental impacts that could be attributed to stormwater runoff associated with induced growth and estimate the maximum potential for stormwater contamination for each alternative.
- Describe how existing ditches along rail corridors that will be improved to ensure proper drainage will be designed to meet specifications listed in the Massachusetts Stormwater Handbook, Volume 2, so that they qualify as stormwater treatment BMPs.
- Include provisions in the Maintenance plan that prohibit the use of herbicides within Aquifer Protection Districts.
- Include in the project plans a Performance Guarantee against potential releases of Oils or Hazardous Materials that result in the contamination and subsequent disuse of drinking water wells.
- Provide for a 2-year pre-construction period of water quality testing and analysis to establish baseline conditions of the water bodies that would be receptors of aerial deposition of diesel exhaust.
- Update the 2006 MADEP's Massachusetts Integrated List of Waters with the most recent available MADEP data.
- Confirm the classifications identified for the water bodies described in Section 4.17.2.2 with the MassDEP.

This section evaluates specific impacts of each of the proposed alternatives to these water resources. Section 4.17.3.2 explains the methodology for evaluating direct and indirect impacts to water resources and describes potential pollutant sources. Section 4.17.3.3 identifies specific locations where impacts to water resources would occur under each alternative and discusses potential types of impacts. Section 4.17.3.5 summarizes the impacts that would be anticipated under each alternative. Section 4.17.3.6

summarizes the proposed mitigation measures to protect water resources, including steps taken to avoid impacts to water resources, possible ways to minimize impacts, and specific mitigation measures. Section 4.17.3.7 discusses the alternatives' compliance with relevant regulatory programs.

4.17.3.2 Impact Assessment Methodology

As required by the NEPA CEQ[9] the analysis of the environmental consequences requires discussion of the direct and indirect effects of a proposed action, and their significance. Direct effects are defined as those "which are caused by the action and occur at the same time and place."[10] Indirect effects are defined as those "which are caused by the action and are later in time or farther removed in distance, but are still reasonably foreseeable. Indirect effects may include growth inducing effects and other effects related to induced changes in the pattern of land use, population density or growth rate, and related effects on air and water and other natural systems, including ecosystems."[11]

Similarly, MEPA requires "a detailed description and assessment of the negative and positive potential environmental impacts of the Project and its alternatives. The EIR [Environmental Impact Report] shall assess (in quantitative terms, to the maximum extent practicable) the direct and indirect potential environmental impacts from the Project that are within the Scope. The assessment shall include both short-term and long-term impacts for all phases of the Project (e.g., acquisition, development, and operation) and cumulative impacts of the Project, any other Projects, and other work or activity in the immediate surroundings and region."[12]

For surface and groundwater resources, direct and indirect effects can usually be considered together, since direct and indirect effects are caused by the same sources. For example, any off-site or downstream impacts would have to be caused by on-site drainage or pollutant sources.

Potential effects on surface and groundwater resources were evaluated by reviewing areas where new construction would be required for each of the alternatives. For the purposes of this evaluation, "new construction" is defined as construction of stations and layover facilities, upgrades of existing rail lines, reconstruction of removed railroad infrastructure (e.g., old rails, ties, etc.) along historic railroad alignments, replacement of existing railroad bridges and culverts, construction of new permanent or temporary railroad bridges, reconfiguration of at-grade road/railroad crossings, and construction of new grade-separated road/railroad crossings. The purpose of this review was to identify where the rail corridors, stations, or layover facilities would pass through or be located in or adjacent to surface and groundwater resources or water resource protection areas. Maps and aerial photographs were examined in reference to preliminary engineering plans to identify potential effects on surface and groundwater resources.

Track and signal improvements are required throughout the system in order to provide commuter rail service that meets the project purpose. These improvements include minor alterations to vertical and horizontal track geometry, reconstruction of grade crossings and bridges, replacement of rail stock, and drainage improvements.

---

[9] Code of Federal Regulations (CFR), Title 40: Protection of the Environment, Part 1502- Environmental Impact Statement, Section 1502.16 Environmental Consequences (40 CFR 1502.16).

[10] 40 CFR 1508.8(a).

[11] 40 CFR 1508.8(b).

[12] 301 Code of Massachusetts Regulations, Title 11.00: MEPA Regulations. Section 11.07- EIR Preparation and Filing, (6) Form and Content of EIR, (h) Assessment of Impacts. (11 CMR 11.07(6)(h)).

Throughout much of the project area, the existing track infrastructure included ditches along both sides of the track for drainage. These ditches have, in many places, been filled or blocked. As part of the proposed drainage improvements, the existing drainage features (ditches and culverts) would also be reconstructed in conjunction with the reconstruction of both active rail lines and the out of service segments. In general, these existing features follow the topography and natural drainage patterns of the corridor and would be rehabilitated or maintained as required in support of the project. In areas where the existing corridor alignment would be changed, the track profile would be altered, or subsequent development or disuse has eliminated surface drainage features, improved drainage features would be required. Improved stormwater management measures would be incorporated into the drainage design in order to comply with the DEP Stormwater Standards.

Although the horizontal and vertical track alignments have been refined since the DEIS/DEIR, the detailed grading plans and drainage analysis cannot be performed until a ground survey with 1-foot contours has been completed. Detailed grading plans and drainage analysis for the track would be completed in conjunction with final design. Specific drainage features have been developed in accordance with the requirements of the Secretary's Certificate. These features would be used where needed throughout the project area, particularly in stormwater critical areas or where other sensitive receptors are located.

For the impact analysis in Section 4.17.3.3, *Impacts of Alternatives by Element and Area*, potential stormwater discharges were identified based on the locations of any proposed stormwater outfalls, such as outlets from ditches, underdrains, detention ponds, or any other stormwater management features. In order to assess impacts conservatively, all discharges to waterbodies from a proposed drainage system were considered new discharges except where the proposed design would reuse a known, existing discharge point. In areas where no information was available on existing drainage designs, all proposed stormwater discharges should be assumed to be new discharges. Existing stormwater drainage features will be identified as the designs are refined, and the existing ditches and discharge points will be reused wherever possible throughout the project.

Potential impacts to drinking water wells were identified based on proposed activities within groundwater protection areas such as Zone I and Zone II areas. These protection areas are established by MassDEP around registered public drinking water supplies. Residences in some areas may not be served by municipal water systems but instead rely on individual private wells that may be located in proximity to one or more alternatives. An analysis of individual impacts to private wells was not performed for this report, but the steps taken to minimize the potential for groundwater contamination and drinking water supply impairment under each alternative would also reduce the potential for any impacts to private wells. Prior to the construction of any element discussed in this report, private wells would be located and inventoried. Based on this inventory, appropriate design modifications would be undertaken to minimize or avoid impacts to private wells.

Method for Assessing Direct Impacts

The limits of work proposed for each alternative were assumed to be the maximum extent of direct impacts. Potential direct impacts to water quality and quantity may result from a variety of actions:

- **Fill within surface waters**: Placing fill within a waterbody can disrupt the ecology of the streambed or lakebed and potentially increase flooding. During the construction period, placing fill may temporarily increase suspended sediment concentrations as well as the risk of contamination from spills or accidents with construction equipment.

- **Discharge of pollutants to surface waters**: Pollutants associated with the construction or operation of the project may contaminate local surface waters if spill controls and stormwater management features are not provided to contain or remove the pollutants. Contamination may occur from contaminated stormwater runoff or direct spills into a waterbody.

- **Discharge of pollutants to groundwater**: Pollutants associated with the construction or operation of the project may contaminate local groundwater supplies if spills or contaminated runoff are allowed to infiltrate into the ground. The potential consequences increase the closer the pollution source is to drinking water wells, as contamination close to a well may require additional treatment at the well to make the water safe to drink.

- **Changes in surface water hydrology**: Building new impervious surfaces, modifying channel geometry (such as by altering the shape of a culvert or the hydraulic opening beneath a bridge), or otherwise changing local drainage patterns can affect any receiving waters. Adding impervious surfaces to a watershed may change the hydrology by increasing the amount of runoff from precipitation. This can increase peak flows in surface waters, as flow rates during storms could increase due to the greater volume and rate of runoff. Increased peak flows of runoff can also promote erosion of soil and streambeds and potentially increase flooding. Changes in hydrology can also decrease or relocate flow, resulting in draining wetlands and streams.

- **Changes in groundwater recharge**: Building new impervious surfaces or otherwise changing local drainage patterns can reduce groundwater recharge, potentially reducing local groundwater supplies. Without mitigation, large-scale reductions in the groundwater supply may make low flows in streams more frequent and severe due to reduced baseflow (groundwater seeping into the stream through the streambed).

Method for Assessing Indirect Impacts

Direct impacts involving substantial changes to site hydrology or pollutant sources may also cause additional downstream impacts and increase the potential for flooding. These causes of these indirect (offsite) impacts are similar to those described under direct impacts.

- **Changes in stream geomorphology:** Increased peak flows result in bank erosion and/or down-cutting of stream systems. Sediment transported from eroding stream segments is deposited downstream in still water areas, resulting in shallower channels, higher water temperatures, and loss of deep water habitat.

- **Changes in bordering vegetated wetlands**: Stream down-cutting and reduced groundwater recharge impact adjacent bordering vegetated wetlands because lowered groundwater levels stress or eliminate wetland species as a result of the drying out that occurs.

- **Changes in water chemistry**: Some types of water-borne pollution are not harmful in and of themselves, however their presence may mobilize or alter naturally-occurring substances in ground or surface water that are harmful to aquatic life or are detrimental to human health.

- **Changes in water temperature**: Increases in water temperature, due to the discharge of cooling water from plants can disrupt the aquatic habitat values within waterbodies. In

addition, impervious surfaces like asphalt can absorb heat thereby, increasing the temperature of runoff, which adversely affects the temperature of the aquatic habitat in the receiving waters.

Method for Assessing Potential Pollutant Sources

Each alternative was assessed for any new pollutant sources that would be introduced, such as potential contaminants associated with the construction or operation of the alternative and any hazardous materials stored or used at or along the corridor (rail greasers, traction power stations, etc.). Depending on their design and location, these sources may or may not increase the risk of water resource contamination. The direct impact analysis pays specific attention to Zone I and Zone A drinking water protection areas, which merit the greatest consideration and protection in order to maintain the quality of regional drinking water supplies. Construction and operation of the South Coast Rail project is allowable within Zone I and Zone A areas, but potential pollutant sources must be managed carefully and contained to prevent any emissions or spills from contaminating drinking water supplies or other sensitive water resources.

Rail lines generate different types of stormwater pollutants than highways, parking lots, and other paved surfaces. Unlike the station sites and layover facilities, the track requires a more decentralized approach to stormwater management because the track is a linear feature with nearly negligible width and no centralized location where stormwater BMPs could be constructed. This section describes the potential contaminants that may be encountered along the rail corridor and are considered in the water resource impact analysis.

The various potential sources of pollutants that could be generated by the South Coast Rail project were reviewed in order to determine the different types of treatment measures that would be required to protect surface and groundwater resources. Most potential rail contaminants are due to the train traffic on the rails, which may result in hazardous contamination from spills, drips, or exhaust. Rail lines themselves are not significant sources of pollutants, as the rails and ballast are made of stable, non-hazardous materials. Most pollutants generated by train operations would be found adsorbed (attached) to the surface of the stone ballast supporting the rail ties. Rail lines generate different types of stormwater pollutants than highways, parking lots, and other paved surfaces. This section summarizes the major rail pollutant sources that are considered in the design of track drainage BMPs.

Hydrocarbons are the most common contaminants found on rail ballast, primarily from drips of fuel or other fluids from trains. Rail greasers are also used to lubricate the inside edges of the rails near tight curves to reduce wheel friction and noise. Excess grease may build up on the nearby ballast and contribute additional hydrocarbons to stormwater and groundwater.

For the Stoughton and Whittenton Electric Alternatives, traction power substations would be required at intervals along the corridor to provide power for the locomotives. The transformers in these power stations would be filled with oil, which could contaminate local water resources in the event of a leak or other accident. Transformers at traction power substations would incorporate secondary containment systems to prevent the release of oil as the result of a leak or other accident.

Train operations may generate trace amounts of iron, which wears off train steel wheels and steel rails. Brake pads may also contain metals such as zinc that are worn off as the brakes are used for slowing and stopping the train. It is not anticipated that metals from either source would be generated in sufficient quantities to pose a threat to surface or groundwater resources.

Commuter trains incorporate on-board sanitary facilities and therefore store and transport sanitary waste during everyday operations. The sanitary waste (pathogens) could pose a risk to water resources if the storage tanks were to leak during travel or spill during unloading. Unloading of sanitary sewage would be performed at an existing MBTA maintenance facility. Leaks and spills of sanitary sewage would be considered an illicit discharge and are prohibited by the Stormwater Standards and the Clean Water Act. A leak or spill would also violate the TMDL waste load allocation (WLA) in watersheds with approved pathogen TMDLs, as the WLA for illicit discharges is zero. The off-loading of sanitary sewage is proposed to occur at the mid-day layover facility and would be addressed in a separate report for that facility once a site is selected.

In contrast to roadways or buildings, the track and associated ballast are pervious surfaces that would generate negligible quantities of total suspended solids (TSS). However, significant quantities of TSS can be released as a result of construction activities, when large areas of exposed soil may be present. A Stormwater Pollution Prevention Plan (SWPPP) would be developed during final design that would identify BMPs that would be used to protect receiving waters from sediment discharges during the construction period. Aeolian (i.e., wind or atmospheric) deposition of fine particles that can be suspended by stormwater runoff would not be altered by the project. Such particles may be trapped by the ballast or may run off into the drainage system, much as occurs under existing conditions. As a result, aeolian depositions are not considered contaminants of that require treatment. Outlets from closed drainage systems and other drainage discharge points can cause erosion and release sediment into the receiving waterbody. New and reconstructed swales within the rail corridor would include water quality features such as check dams, sediment forebays, and outlet protection stone to reduce the concentration of TSS in runoff from the project area.

The rail lines would require limited use of herbicides to keep the rail corridors free of intrusive or obstructive vegetation. Overuse of herbicides near surface waters could introduce herbicides into surface waters and damage the overall health and biodiversity of waterbodies downstream. Comments on the DEIS/DEIR included the request that MassDOT provide a commitment to develop an approved Vegetation Management Plan (VMP) restricting the use of herbicides near Aquifer Protection Districts. Chapter 4.14, *Biodiversity, Wildlife, and Vegetation*, discusses the use of herbicides along the track corridor and describes the VMP that would be developed for the project.

The Stoughton and Whittenton Electric Alternatives would not generate any exhaust within the rail corridor. If the Stoughton Diesel Alternative was selected, a small amount of emissions would be generated by train locomotives. However, aerial deposition of train-generated emissions is not a significant source of pollution of water resources because of the very low concentrations of pollutants in the vicinity of the track. Because trains are moving at operating speeds, emissions are dispersed over a large area and are not deposited adjacent to the track. Air quality and locomotive emissions are discussed in Chapter 4.9 of the FEIS/FEIR.

Potential Roadway Pollutants

Roadways, parking lots, and other impervious surfaces associated with the stations can contribute stormwater pollutants that are generated or deposited by the traffic they convey. However, stormwater that runs across these surfaces carry pollutants from other sources such as nearby land uses, wildlife and atmospheric deposition. The impact caused by an impervious area varies depending on the type of use that it receives, which can include new access roads, stations, parking areas, and layover facilities. Pollutants can collect on impervious surfaces and contaminate runoff, particularly the “first flush” of

runoff at the beginning of a storm. Airborne deposition of nutrients and pollutants can occur on both paved and unpaved areas. The largest source of airborne pollutants on a roadway is from vehicular exhaust. Therefore, pollutant loading from paved surfaces is more directly correlated to the amount and type of traffic they receive rather than the total area of pavement. For example, a heavily-travelled roadway or high-turnover parking lot is subject to greater deposition of hydrocarbons, salts, heavy metals, and exhaust by vehicles and road treatments than lower-usage facilities of comparable size. As a result, higher-usage areas can contribute greater quantities of pollutants to runoff.

As a result of fecal deposition by birds and other wildlife, impervious surfaces may contribute some bacteria to stormwater, but they are not a major source of bacteria when compared to the potential impacts of septic systems or combined sewer overflows (CSOs). The potential for bacteria contribution varies with the type of roadway. Local roads where wildlife and domestic pets have abundant access are more likely to contribute bacteria to stormwater than highways that offer little or no access for animals and pedestrians.

Impervious surfaces like asphalt also absorb heat and can therefore increase the temperature of runoff, affecting the temperature of the aquatic habitat in the receiving waters. The increase in impervious surfaces could therefore have an impact on the temperature of runoff, just as the urbanized runoff from neighborhoods is warmer than runoff from vegetated areas. The travel of runoff through swales and surface channels prior to reaching any major waterbodies would reduce the thermal impact by evaporation and infiltration.

Methods to Assess Compliance with Stormwater Management Standards

The stormwater management features at each station site and layover facility were evaluated for compliance with state and federal stormwater regulations and with the requirements of the Secretary's Certificate. State regulations include the Stormwater Regulations at 310 CMR 10.05(6)(k); the Surface Water Quality Standards at 314 CMR 4.00; and the Clean Water Act Section 401 Water Quality Certification at 314 CMR 9.00. Federal regulations include the National Pollutant Discharge Elimination System (NPDES) regulations under the Clean Water Act (33 U.S.C. §1251 et seq.) and the Federal Water Pollution Control Act (33 U.S.C. §1342).

Evaluations were conducted for the five new stations that would discharge stormwater runoff to wetlands and would require compliance with the Massachusetts Stormwater Standards. The evaluations included hydrologic analysis, hydraulic analysis, geotechnical analysis, floodplain review, and Environmentally Sensitive Site Design (ESSD) and Low Impact Development (LID) evaluations. Non-structural BMPs for water quantity and quality control were evaluated for each station site and would be further refined during the final design process. Non-structural BMPs include measures such as snow management, spill prevention, and source control practices. Structural BMPs for water quantity and quality control were also evaluated for each station site and were selected to provide treatment trains appropriate for each site. Structural BMPs include catch basins with deep sumps and hoods, oil/grit separators, vegetated filter strips, vegetated swales, bioretention swales, bioretention basins, and infiltration basins. These analyses were not conducted for the relocated Stoughton Station as this site has not yet been advanced to preliminary design; these analyses would be conducted at a future date.

For the Weaver's Cove East Layover Facility, these evaluations included hydrologic analysis, hydraulic analysis, geotechnical analysis, floodplain review, and ESSD and LID evaluations. Except for floodplain review, these analyses were not conducted for the Wamsutta Layover Facility as this site has not yet been advanced to preliminary design; these analyses would be conducted at a future date. Non-

structural BMPs for Water Quantity and Quality Control were evaluated for each layover facility and would be further refined during the final design process. Non-structural BMPs include measures such as Snow Management, Spill Prevention, and Source Control practices. Structural BMPs for Water Quantity and Quality Control were also evaluated for each layover facility and were selected to provide treatment trains appropriate for each site. Structural BMPs include drip trays, catch basins with deep sumps and hoods, oil/grit separators, gravel and grass filter strips, vegetated swales, sediment forebays, and infiltration basins.

Railroad layover facilities are considered a LUHPPL as defined in 310 CMR 10.04 and 314 CMR 9.02. As a result, certain BMPs are required to prevent contamination of local wetlands and water resources such as the New Bedford Inner Harbor or the Taunton River. The storage tracks would have drip pans (collection trays) to catch any incidental drips, leaks, or spills of hazardous materials that may occur during storage or maintenance. The drip pans would be connected to an oil/grit separator that would separate petroleum products from stormwater runoff prior to discharge, protecting wetland and water resources from contamination. Any oil or other hazardous materials stored at the site would be secured with secondary containment structures to catch any spills. With the proposed containment measures in place, neither layover facility would pose a significant risk to surface or groundwater resources. The electric alternatives and the diesel alternatives differ as follows with regard to potential pollutants:

- Fuel spills and ballast contamination is a greater concern for alternatives using diesel locomotives than for those with electric ones, since the electric vehicles would not use any diesel fuel or generate any exhaust. However, aerial deposition of diesel train-generated emissions is not a significant source of pollution of water resources because of the very low concentrations of pollutants in the vicinity of the track. Since trains are moving at operating speeds, emissions are dispersed over a large area and are not deposited adjacent to the track.

- Electric railroads require traction power substations to provide power for the locomotives. The transformers in these power stations would be filled with oil, which could contaminate local water resources in the event of a leak or other accident.

4.17.3.3 Impacts of Alternatives by Element and Area

This section evaluates the potential impacts to surface and groundwater resources associated with the alternatives. These alternatives include the No-Build Alternative (Enhanced Bus), Stoughton Alternative (Electric and Diesel), and Whittenton Alternative (Electric and Diesel). The alternatives considered would include construction of new rails, stations, and layover facilities. Figure 4.17-1 shows the major surface waterbodies throughout the project area. Figure 1.4-1 shows the route for each alternative and proposed station locations.

No-Build (Enhanced Bus) Alternative

The No-Build Alternative would improve transit service to Boston from New Bedford, Fall River, and Taunton by adding more buses and improving park-and-ride capacity and amenities with smaller capital investments than are proposed in the Build Alternatives. Under this alternative, no new rail or bus service would be provided to Southeastern Massachusetts. Three existing park-and-ride facilities (West Bridgewater, Mt. Pleasant Street, and Silver City Galleria) would be improved as part of the No-Build Alternative.

The West Bridgewater Park-and-Ride is near the southwest corner of the intersection of Routes 106 and 24 in West Bridgewater. Under the No-Build Alternative, the existing parking lot would be restriped for optimal capacity and efficiency. The improvements would occur within the existing lot and would not add any impervious surfaces or new pollutant sources. No changes to stormwater drainage would occur, and there would be no impact to water resources.

The Mt. Pleasant Street Park-and-Ride is on the northwest corner of the intersection of King's Highway and Route 140 in New Bedford. Under the No-Build Alternative, the existing lot would remain unchanged, and a new pickup location would be added using the existing parking lot at the proposed Whale's Tooth Station. Due to the existing uses of these sites and the proximity to existing highways and parking areas, changes to the park-and-ride facility would not introduce any new uses or pollutant sources to the area. There would be no expansion or construction needed for either parking lot, resulting in no new impervious area and no impact on waterbodies or drinking water protection areas.

The Silver City Galleria Park-and-Ride is adjacent to the Silver City Galleria shopping mall in Taunton. Under the No-Build Alternative, the existing parking lot would be restriped for optimal capacity and efficiency. The improvements would occur within the existing lot and would not add any impervious surfaces or new pollutant sources. No changes to stormwater drainage would occur, and there would be no impact to water resources.

As under existing conditions, the park-and-ride facilities would contribute roadway pollutants such as metals, hydrocarbons, salt, and sediment, all of which are associated with automobile traffic. The improvements to the park-and-ride facilities would not introduce new pollutant sources and would be expected to be, at most, incremental. No impacts to water resources are expected from expanding the park-and-ride facilities for the No-Build Alternative. These facilities would increase parking capacity in existing developed areas and would not substantially increase impervious area, automotive traffic, or stormwater pollution.

Build Alternatives

This section first describes typical stormwater management facilities and methods common to all Build Alternatives. This is followed by a discussion of impacts in the Southern Triangle, which is common to all Build Alternatives. This is followed by a description of impacts in the northern part of the South Coast Rail study area where the Build Alternatives differ in their alignments and where impacts are discussed separately for each alternative. This is followed by a description of impacts associated with station sites and layover facility sites for the entire study area.

Track Drainage (Common to all Build Alternatives)

As previously mentioned, the track requires a more decentralized approach to stormwater management because the track is a linear feature with nearly negligible width and no centralized location where stormwater BMPs could be constructed. The existing track infrastructure included ditches along both sides of the track for drainage. In many places, these ditches have been filled or blocked and are no longer capable of providing adequate drainage for the rail bed. As part of the track reconstruction project (in all segments of the rail lines), these ditches would be reconstructed to maintain proper drainage.

Under both existing and proposed conditions, stormwater would be conveyed through overland flow and through a drainage system consisting of drainage ditches alongside the tracks or underdrains installed in the rail ballast. In areas where no ditches or underdrains would be required to keep the rail

bed dry, such as areas where the rail would be elevated above the surrounding land, stormwater is assumed to leave the rail corridor by overland flow, resulting in no point discharges of stormwater. In areas where the rail would run through a cut section, ditches and underdrains would be required to direct stormwater to safe discharge locations and to keep the ballast dry and stable.

Discharges from track drainage would be directed away from stormwater critical areas such as Outstanding Resource Waters (ORWs) and into adjacent upland areas to the maximum extent practicable. ORWs in the vicinity of the track include vernal pools, wetlands and waterways within the Hockomock Swamp ACEC, and tributaries to surface drinking water supplies. Selection of appropriate treatments for each location would occur during final design as part of the detailed grading plans and drainage analysis. Any treatments proposed would be constructed in a manner consistent with other measures intended to avoid, minimize and mitigate wildlife habitat impacts including between tie passages to facilitate movement of wildlife across the railbed, as well as the trestle within a section of the Hockomock Swamp.

A number of stormwater Best Management Practices (BMPs) would be incorporated. Drainage into the underdrains would contain minimal pollutants, as most suspended solids and other contaminants would be caught in the ballast above the underdrains. The use of surface ditches would allow stormwater infiltration as well as settling of suspended solids, reducing stormwater volumes and contaminant loads prior to discharge to any waterbodies or wetlands. Sediment forebays and check dams would be installed upstream of discharge points to provide additional sediment removal. Outfalls would be protected using crushed stone or concrete structures, as appropriate, to prevent erosion in the receiving waters or wetlands. Because the surface of the rail corridor consists of pervious stone ballast and does not include new impervious surfaces, there would be no change in the peak discharge rate from the rail corridor and no BMPs that provide rate control are required.

In accordance with the Secretary's Certificate, drainage improvements are proposed that would protect wetland and water resources in the vicinity of the rail corridor. Stormwater and drainage design plans from the Greenbush Commuter Line project, completed in 2007, were reviewed and stormwater management features from the track design have been incorporated into the project design. The specific percentage of credit granted for TSS removal from proposed measures would be evaluated as stormwater system design details become developed. MassDEP would be consulted during the design of project elements to ensure these standards are implemented.

Track drainage elements include vegetated drainage swales, sediment forebays with check dams, perforated pipe underdrains, stone swales with high density polyethylene (HDPE) liners, outlet protection stone, and infiltration trenches. These BMPs and the criteria used to determine where particular treatments should be used are described below.

Vegetated Drainage Swales

Vegetated drainage swales are proposed in order to provide positive drainage for the track ballast, maintain open space, and to allow runoff to infiltrate to the extent practicable. Side slopes of the swale may be no steeper than 2:1 and the floor of the swale must be at least 2 feet wide. The longitudinal slope of the swale must be less than 5 percent and maximum velocities should be less than 1 foot per second during the water quality event. Swales should end at sediment forebays with check dams. A typical detail and plan view of a vegetated drainage swale is shown on Figure 4.17-6.

Sediment Forebays

Sediment forebays with stone check dams are proposed at locations where swales discharge runoff to wetland resource areas. A typical detail and plan view of a sediment forebay and stone check dam is shown on Figure 4.17-6.

Perforated Pipe Underdrains

Perforated pipe underdrains are proposed for locations where the track corridor is constrained or where the adjacent grading does not allow open channel flow. Per MBTA design guidelines, a minimum pipe size of 12 inches is required. Underdrains shall be bedded in a trench filled with ¾-inch crushed stone wrapped in filter fabric. Cleanouts shall be spaced no more than 500 feet apart. A typical detail and plan view of a perforated pipe sub-drain is shown on Figure 4.17-7.

HDPE-Lined Swales

Stone-lined swales with HDPE liners are proposed in locations where the track is less than 200 feet from the Zone 1 of a drinking water supply well. This occurs in the vicinity of the Easton GP Well #1 on Gary Lane in Easton. In accordance with MassDEP regulations, drainage in this area would be directed away from the Zone 1. A typical detail and plan view of a stone-lined swale with an HDPE liner is shown on Figure 4.17-8.

Stone-lined swales with HDPE liners are also proposed in locations where vernal pools are located immediately adjacent to the track in order to prevent the track drainage from dewatering the pool. These locations would use the same detail as shown on Figure 4.17-8

Outlet Protection

Stone-lined scour protection pads are proposed at each end of swale and pipe segments to protect adjacent soils from erosion and to trap coarse debris. Scour protection stone and energy dissipation bowls must be sized for the discharge rates anticipated at each outlet. Details of a flared end section with stone scour protection and a headwall with stone scour protection are shown on Figure 4.17-9**.**

Southern Triangle Study Area (Common to All Build Alternatives)

Portions of the rail lines within the southern part of the South Coast Rail study area are common to all Build Alternatives (Figures 4.17-3a-c and 4.17-2a-e). These rail lines form a rough triangular shape running from Fall River to Myricks Junction (the Fall River Secondary Line) and from New Bedford to Weir Junction (the New Bedford Main Line), and are referred to as the Southern Triangle. Potential impacts to water resources along the Southern Triangle are described below.

Fall River Secondary Rail Segment

The existing Fall River Secondary freight track would be upgraded to Federal Rail Administration (FRA) Class 5[13] for the South Coast Rail project. Two new stations would be constructed in Fall River (Battleship Cove and Fall River Depot) and one in Freetown (Freetown). One new layover facility would be constructed in Fall River, at the Weaver's Cove site. Potential impacts to water resources resulting

[13] 49 CFR 213.9 Classes of Track: Operating Speed Limits

from developing the new stations and layover facilities are considered in the sections on Station and Layover Facility sites, respectively.

Table 4.17-13 lists waterbodies near the Fall River Secondary and identifies the waterbodies that would receive stormwater discharges from the rail line. Forge Pond, the Assonet River, and the Taunton River would all receive stormwater discharges from the rail drainage system. There would also be a discharge near the confluence of the Quequechan River and the Taunton River that would not affect the Quequechan River upstream. All other stormwater discharges from the Fall River Secondary would go to local wetland systems rather than to named waterbodies. Cedar Swamp River, Rattlesnake Brook, and Steep Brook would be crossed by the line but would not receive any direct stormwater discharges. No Zone A areas or groundwater protection areas (Zone I, Zone II, etc.) would be crossed by this line or receive any stormwater discharges. Potential impacts from the construction of culverts and other waterway crossings are discussed in Chapter 4.16, *Wetlands.*

Table 4.17-13 Stormwater Discharges on the Fall River Secondary Line

Waterbody	Municipality	ACEC/ ORW	Stormwater Discharges Proposed
Assonet River	Lakeville	No	Yes
Cedar Swamp River	Lakeville	No	No
Forge Pond (Freetown)[1]	Freetown	No	Yes
Quequechan River	Fall River	No	No[2]
Rattlesnake Brook	Freetown	No	No
Steep Brook	Fall River	No	No
Taunton River	Fall River	No	Yes
Terry Brook[3]	Freetown	No	Yes

1 This Forge Pond is separate and distinct from the Forge Pond in Canton.
2 A stormwater discharge occurs near the confluence of the Quequechan River and the Taunton River but would not affect the Quequechan River.
3 The Fall River Secondary crosses Terry Brook Pond, an impounded section of Terry Brook that is bisected by the Fall River Secondary alignment.

The stormwater discharges from the Fall River Secondary segment would not be expected to contribute contaminants that would impair any of these waterbodies. No new impervious surfaces would be constructed as part of the rail line itself, resulting in no changes in runoff rates. The track upgrades and new traffic would not introduce new pollutant sources because the Fall River Secondary rail segment is already an active rail line.

As described in Section 4.17.3.2, *Impact Assessment Methodology*, the rail corridor would use a combination of drainage ditches alongside the tracks and underdrains installed in the rail ballast to keep the railbed dry and stable. Potential temporary, construction-period impacts to surface and groundwater resources are discussed in Section 4.17.3.4, *Temporary Construction Impacts*. Mitigation proposed to prevent contamination of surface and groundwater resources from the pollutant sources discussed in the section on Potential Pollutant Sources are discussed in Section 4.17.3.6, *Mitigation*.

New Bedford Main Line Rail Segment

The existing New Bedford Main Line freight track would be upgraded to FRA Class 5 for the South Coast Rail project. Two new train stations would be constructed in New Bedford (Whale's Tooth and King's Highway) and one near Taunton (Taunton Depot). One new layover facility would be constructed in New

Bedford, at the Wamsutta site. Potential impacts to water resources resulting from developing the new stations and layover facilities are considered in the sections on Station and Layover Facility sites, respectively.

Table 4.17-14 lists waterbodies near the New Bedford Main Line and identifies the waterbodies that would receive stormwater discharges from the rail line. In Taunton, the Taunton River would receive stormwater discharge from the rail drainage system. All other stormwater discharges from the New Bedford Main Line would go to local wetland systems or municipal systems rather than directly to named waterbodies. Cedar Swamp River, Cotley River, and Pierce Brook would be crossed by the line, and New Bedford Inner Harbor is close to the line, but none of these waterbodies would receive any stormwater discharges from the proposed drainage system. There would be no direct stormwater discharges to Fall Brook, which is an Outstanding Resource Water (ORW). There would be stormwater discharges to the combined Zone A area associated with Fall Brook, Assawompset Pond, Long Pond, and Pocksha Pond. These discharges would be allowable under Massachusetts Stormwater Management Standards (310 CMR 10.05(6)) and the proposed Stormwater Management Regulations (314 CMR 21.00) because the New Bedford Main Line is an existing rail line. Zone A discharges are allowable if they originate on previously-developed impervious surfaces and if the discharge does not increase pollutant loadings to the drinking water supply in question. The improvements proposed to the New Bedford Main Line would not add any impervious surfaces to this area or increase pollutant loadings to Fall Brook or the water supplies downstream.

Table 4.17-14 Stormwater Discharges on the New Bedford Main Line

Waterbody	Municipality	ACEC/ORW	Stormwater Discharges Proposed
Assawompset Pond (Zone A only)	Freetown, Lakeville	No	Yes (Zone A only)
Cedar Swamp River	Lakeville	No	No
Cotley River	Berkley	No	No
Fall Brook (includes Zone A)	Freetown	Yes	Yes (Zone A only)
Long Pond (Zone A only)	Freetown, Lakeville	No	Yes (Zone A only)
New Bedford Inner Harbor	New Bedford	No	No
Pierce Brook	Lakeville	No	No
Pocksha Pond (Zone A only)	Freetown, Lakeville	No	Yes (Zone A only)
Taunton River	Taunton	No	Yes

None of the substations proposed on this line for the electrically-powered alternatives would be located in any Zone A areas or groundwater protection areas. Potential impacts from the construction of culverts and other waterway crossings are discussed in Chapter 4.16, *Wetlands.*

All Build Alternatives would require construction within the interim wellhead protection areas (IWPAs) for the two wells operated by the Freetown-Lakeville Regional School District in Lakeville. The wells are approximately 0.5 mile east of the New Bedford Main Line. There would be no stormwater discharges within this IWPA, with drainage redirecting stormwater flows to the west side of the tracks away from the wells.

The stormwater discharges from the New Bedford Main Line would not be expected to contribute contaminants that would impair any waterbodies or water supplies. No new impervious surfaces would be constructed as part of the rail line itself, resulting in no changes in runoff rates. The track upgrades and new traffic would not introduce new pollutant sources because the New Bedford Main Line is already an active rail line.

There would be no stormwater discharges within the IWPA for the Freetown Lakeville Regional School District. The existing stormwater discharges to the Zone A area for Fall Brook, Assawompset Pond, Long Pond, and Pocksha Pond would continue, but there would be no new impervious surfaces or pollutant sources tributary to this Zone A area. Due to the low potential for pollutant generation on the rail line, no impacts are expected to groundwater quality.

As described in Section 4.17.3.2, *Impact Assessment Methodology,* the rail corridor would use a combination of drainage ditches alongside the tracks and underdrains installed in the rail ballast to keep the railbed dry and stable. Potential temporary, construction-period impacts to surface and groundwater resources are discussed in Section 4.17.3.4, *Temporary Construction Impacts*. Mitigation proposed to prevent contamination of surface and groundwater resources from the pollutant sources discussed in the section on Potential Pollutant Sources are discussed in Section 4.17.3.6, *Mitigation.*

Stoughton Electric Alternative

The Stoughton Electric Alternative alignment would be comprised of a portion of the Northeast Corridor and the Stoughton Line (Figures 4.17-4a-e). This alternative would use the Northeast Corridor from South Station to Canton Junction, and the existing Stoughton Line from Canton Junction to Stoughton Station. From that point, commuter rail service would be extended, using an out-of-service railroad bed, south through Raynham Junction to Weir Junction in Taunton, where it would join the northern end of the Southern Triangle. This evaluation focuses on the Stoughton Line component only. This alternative would include the following stations: Canton Center, Stoughton, North Easton, Easton Village, Raynham Park, and Taunton. No layover facilities are planned within this segment. Potential impacts to water resources resulting from developing the new stations are considered in the section on Stations.

The existing Stoughton Line commuter rail track from Canton Junction to Stoughton would be upgraded to FRA Class 5 for the Stoughton Electric Alternative. New track would be placed on the railroad bed from Stoughton south to Weir Junction. A section from Foundry Street in Easton to Raynham Station through the Hockomock Swamp would be constructed on an elevated trestle. Two existing train stations along the Stoughton Line would be reconstructed (Canton Center and Stoughton). Four new train stations would be constructed along this alignment (North Easton, Easton Village, Raynham Park, and Taunton).

Table 4.17-15 lists waterbodies near the Stoughton Line and identifies the waterbodies that would receive stormwater discharges from the rail line. Beaver Meadow Brook, the East Branch Neponset River, Forge Pond, Mill River, Queset Brook, and the Taunton River would all receive stormwater discharges from the Stoughton Line. Black Brook, which is located within the Hockomock Swamp ACEC, would not receive any stormwater discharges, although there would be stormwater discharges to wetlands and unnamed channels near Black Brook. Black Brook, Pine Swamp Brook, and Whitman Brook would all be crossed by the Stoughton Line but would not receive any stormwater discharges from the proposed drainage system. No Zone A areas would be affected by construction on this line. Potential impacts from the construction of culverts and other waterway crossings are discussed in Chapter 4.16, *Wetlands*.

Table 4.17-15 Stormwater Discharges on the Stoughton Line

Waterbody	Municipality	ACEC/ORW	Stormwater Discharges Proposed
Beaver Meadow Brook	Canton	No	Yes
Black Brook	Easton	Yes[1]	No
East Branch Neponset River[2]	Canton	Yes[3]	Yes
Forge Pond (Canton)[4]	Canton	No	Yes
Mill River	Taunton	No	Yes
Pine Swamp Brook	Raynham	No	No
Queset Brook	Easton	No	Yes
Taunton River	Taunton	No	Yes
Whitman Brook	Easton, Stoughton	No	No

1 Hockomock Swamp ACEC.
2 East Branch Neponset River is sometimes referred to as the Canton River.
3 Fowl Meadow and Ponkapoag Bog ACEC.
4 This Forge Pond is separate and distinct from the Forge Pond in Freetown that is crossed by the Southern Triangle.

The Stoughton Alternative would require construction in Zone II areas for six public water supply wells along the Stoughton Line. There would also be stormwater discharges from the Stoughton Line in the Zone II areas for these six wells. The wells associated with these protection areas include three wells operated by the Easton Water Division and three wells operated by the North Raynham Water District. The individual wells and their protection zones are listed in Table 4.17-16. The Zone II areas crossed by the proposed Stoughton Line already contain developed areas and residential neighborhoods that are likely to have much larger impacts on water quality than a rail corridor. No Zone I areas would be affected by the construction on this line. Since the construction would occur on an out of service railroad bed, there would be no expected change in groundwater flow. No electrical substations would be located in any IWPAs, Zone I areas, or Zone A areas. One electrical substation would be located in the Zone II for Easton GP Wells #1, #2, and #4 and would include secondary containment to minimize the risk of any surface or groundwater contamination from this location.

Table 4.17-16 Construction and Stormwater Discharges in Public Water Supply Well Protection Areas on the Stoughton Line

Well	Distance From Proposed Limit of Work (miles)	Water System	Location of Protection Zone Crossings	Construction in Protection Zones	Stormwater Discharges in Protection Zones
Easton GP Well #1	0.1	Easton Water Division	Easton, Stoughton	Zone II	Zone II
Easton GP Well #2	0.4		Easton, Stoughton	Zone II	Zone II
Easton GP Well #4	0.3		Easton, Stoughton	Zone II	Zone II
King Philip St. Well #3A	0.3	North Raynham Water District	Raynham	Zone II	Zone II
King Philip St. Well #3B	0.3		Raynham	Zone II	Zone II
King Philip Bedrock Well[1]	0.5		Raynham	Zone II	Zone II

1 Proposed well

The stormwater discharges from the Stoughton Line would not be expected to contribute contaminants that would impair any waterbodies or water supplies. No new impervious surfaces would be constructed as part of the rail line itself, resulting in no changes in runoff rates. The portion of the rail corridor that would be built on a trestle would not require any constructed stormwater drainage features as the rails would be elevated above the ground, leaving the existing ground surface in place.

Since the Stoughton Electric Alternative involves reconstructing inactive portions of the Stoughton Line, this alternative would introduce new potential pollutant sources to some waterbodies and to the groundwater protection areas in proximity to the proposed Stoughton Line. However, with appropriate management, containment, and mitigation measures in place, these sources would not be expected to contribute contaminants that would impair any of the waterbodies or drinking water sources along the line. With proper design of the stormwater management system and regular maintenance of the track and trains, the new rail line and train operations would pose a minimal threat to waterbodies and drinking water supplies.

As described in Section 4.17.3.2, *Impact Assessment Methodology,* the rail corridor would use a combination of drainage ditches alongside the tracks and underdrains installed in the rail ballast to keep the railbed dry and stable. Potential temporary, construction-period impacts to surface and groundwater resources are discussed in Section 4.17.3.4, *Temporary Construction Impacts*. Mitigation proposed to prevent contamination of surface and groundwater resources from the pollutant sources discussed in the section on Potential Pollutant Sources, are discussed in Section 4.17.3.6, *Mitigation*.

Stoughton Diesel Alternative

The Stoughton Diesel Alternative is identical to the Stoughton Electric Alternative with the exception of the locomotive power source. As described previously for the Attleboro Diesel Alternative, diesel-powered train service differs from electric-powered service in not requiring electrical infrastructure but instead generating diesel exhaust and increasing the potential risk of fuel spills. Constructing the Stoughton Diesel Alternative along the Stoughton Line would be identical to the Stoughton Electric Alternative except without the new electrical infrastructure required for that alternative. This alternative would be near the same waterbodies and groundwater protection areas discussed for the Stoughton Electric Alternative.

Due to the use of diesel fuel, the Stoughton Diesel Alternative would likely have a higher rate of hydrocarbon accumulation on the rail ballast than the Stoughton Electric Alternative, and there would be a greater chance of fuel spills. However, aerial deposition of diesel exhaust would not be a significant source of pollution of water resources because of the very low concentrations of pollutants in the vicinity of the track. The regular operations proposed for this alternative would not be expected to contribute contaminants that would impair any of the waterbodies or drinking water sources along the line.

Potential temporary, construction-period impacts to surface and groundwater resources are discussed in Section 4.17.3.4, *Temporary Construction Impacts*. Mitigation proposed to prevent contamination of surface and groundwater resources from the pollutant sources discussed in the section on Potential Pollutant Sources, are discussed in Section 4.17.3.6, *Mitigation*.

Whittenton Electric Alternative

The Whittenton Electric Alternative is a variant of the Stoughton Electric Alternative alignment described previously. Specifically, at Raynham Junction near the southern end of the historic Stoughton

Line, the alignment would divert to the southwest, following the old Whittenton Branch (Figures 4.17-5a-b). This alignment would connect with the Attleboro Secondary at Whittenton Junction in Taunton, and then continue southeast to connect with the New Bedford Main Line at Weir Junction, at the northern end of the Southern Triangle. This evaluation focuses on the Whittenton Branch component only. Service along the southernmost portion of the Stoughton Line, from Raynham Junction to Weir Junction, would not be reestablished if this variant were selected. This alternative would include the following stations: Canton Center, Stoughton, North Easton, Easton Village, Raynham Park, and Dana Street. No layover facilities are planned within this segment.

Table 4.17-17 lists waterbodies near the Whittenton Branch and identifies the waterbodies that would receive stormwater discharges from the rail line. Prospect Hill Pond would receive stormwater discharges. Although the Whittenton Branch would cross the Mill River in Taunton, the river would not receive any stormwater discharges from the proposed drainage system. However, discharges to nearby wetlands and municipal systems may eventually reach the Mill River. No Zone A areas would be affected by the Whittenton Branch.

Table 4.17-17 Stormwater Discharges on the Whittenton Branch

Waterbody	Municipality	ACEC/ORW	Stormwater Discharges Proposed
Mill River	Taunton	No	No
Prospect Hill Pond	Taunton	No	Yes

This alternative would require construction within the groundwater protection zones for all seven of the North Raynham Water District's existing and proposed wells, including the Zone I area for King Philip Street Well #2. (It should be emphasized that this alternative would require work within *all* areas of Raynham's water supply.) No other Zone I areas would be affected, and no electrical substations would be located in any IWPAs, Zone A areas, or Zone I areas. The Zone II areas include numerous residential neighborhoods, but the Zone I area for King Philip Street Well #2 is largely undeveloped. The individual wells, their protection zones, and potential impacts are listed in Table 4.17-18. There would be no stormwater discharges in any Zone I areas, but there would be stormwater discharges in the Zone II area shared by these wells.

Table 4.17-18 Construction and Stormwater Discharges in Public Water Supply Well Protection Areas on the Whittenton Branch

Well	Distance from Proposed Limit of Work (miles)	Water System	Location of Protection Zone Crossings	Construction in Protection Zones	Stormwater Discharges in Protection Zones
Noblin Well Field[1]	0.4	North Raynham Water District (all)	Raynham, Taunton	Zone II	Zone II
First St. Replacement Well	0.6		Raynham, Taunton	Zone II	Zone II
King Philip St. Well #1	0.2		Raynham, Taunton	Zone II	Zone II
King Philip St. Well #2	0.02		Raynham, Taunton	Zone I and Zone II	Zone II
King Philip St. Well #3A	0.7		Raynham	Zone II	Zone II
King Philip St. Well #3B	0.6		Raynham	Zone II	Zone II
King Philip Bedrock Well[1]	0.7		Raynham	Zone II	Zone II

1 Proposed well

The stormwater discharges from the Whittenton Branch would not be expected to contribute contaminants that would impair any waterbodies or water supplies. No new impervious surfaces would be constructed as part of the rail line itself, resulting in no changes in runoff rates. Since the Whittenton Electric Alternative involves reconstructing the inactive Whittenton Branch, this alternative would introduce new potential pollutant sources to some waterbodies and to the groundwater protection areas adjacent to the Whittenton Branch. However, with appropriate management, containment, and mitigation measures in place, these sources would not be expected to contribute contaminants that would impair any of the waterbodies or drinking water sources along the line.

With proper design of the stormwater management system and regular maintenance of the track and trains, the new rail line and train operations would pose a minimal threat to waterbodies and drinking water supplies.

As described in Section 4.17.3.2, *Impact Assessment Methodology*, the rail corridor would use a combination of drainage ditches alongside the tracks and underdrains installed in the rail ballast to keep the railbed dry and stable. Potential temporary, construction-period impacts to surface and groundwater resources are discussed in Section 4.17.3.4, *Temporary Construction Impacts*. Mitigation proposed to prevent contamination of surface and groundwater resources from the pollutant sources discussed in the section on Potential Pollutant Sources, are discussed in Section 4.17.3.6, *Mitigation*.

Whittenton Diesel Alternative

The Whittenton Diesel Alternative is identical to the Whittenton Electric Alternative with the exception of the locomotive power source. As described above for the Attleboro Diesel Alternative, diesel-powered train service differs from electric-powered service in not requiring electrical infrastructure but instead generating diesel exhaust and increasing the potential risk of fuel spills. Constructing the Whittenton Diesel Alternative would be identical to the Whittenton Electric Alternative except without the new electrical infrastructure required for that alternative. This alternative would be near the same waterbodies and groundwater protection areas discussed for the Whittenton Electric Alternative.

Due to the use of diesel fuel, the Whittenton Diesel Alternative would likely have a higher rate of hydrocarbon accumulation on the rail ballast than the Whittenton Electric Alternative, and there would be a greater chance of fuel spills. However, aerial deposition of diesel exhaust would not be a significant source of pollution of water resources because of the very low concentrations of pollutants in the vicinity of the track. The regular operations proposed for this alternative would not be expected to contribute contaminants that would impair any of the waterbodies or drinking water sources along the line.

Potential temporary, construction-period impacts to surface and groundwater resources are discussed in Section 4.17.3.4, *Temporary Construction Impacts*. Mitigation proposed to prevent contamination of surface and groundwater resources from the pollutant sources discussed in the section on Potential Pollutant Sources, are discussed in Section 4.17.3.6, *Mitigation*.

Hockomock Swamp Trestle

In order to avoid and minimize impacts to the Hockomock Swamp, a 1.6 mile (8,500 foot) section of track would be constructed on an elevated trestle between Foundry Street and Raynham Station. The trestle would consist of pile bents spaced at 50 foot intervals, with concrete spans supporting a ballasted rail bed and a walkway for railroad maintenance personnel. Drainage from this structure

would be managed in place through the use of infiltration trenches located at intervals beneath the trestle (Figures 4.17-10 thru 12). The remainder of this section describes the drainage design of the trestle and the proposed infiltration trenches.

Trestle Drainage

The trestle would consist of concrete and steel spans that supports a railbed consisting ballast, ties, and track. The ballast would be drained by a 6 inch underdrain (HDPE perforated pipe) that would be laid parallel to the track. The floor of the trestle would be sloped to direct water to the underdrain. In turn, the underdrain would be connected to downspouts located every 300 feet along the length of the trestle. These downspouts would carry runoff to infiltration trenches located beneath the trestle. Runoff directed to the infiltration trenches would infiltrate into the subsurface soils of the existing **railroad** embankment. During large storm events, runoff would also discharge down the slope of the embankment and into wetlands associated with the adjacent Hockomock Swamp.

The proposed infiltration trenches would each be 16 feet wide by 33 feet long. The length of the trenches is constrained by the spacing of the pile bents and the 5 foot setback that is required from each pile bent. The trenches are sized to provide the recharge volume and the 0.5 inch water quality volume. The floor of each trench would be lined with 6 inches of stone to prevent scour and would have a 4-foot long level spreader to act as an overflow weir. Approximately 30 infiltration trenches would be required along the length of the trestle to provide stormwater management for the structure.

Stormwater Analysis

A HydroCAD[14] analysis was performed to evaluate the storage volume of the ballast on the trestle as well as within the infiltration trench. The results of this analysis demonstrate that the peak rate control is met for the 2, 10, and 100 year storm events.

The recharge volume required for the unit discharge area was calculated to be 127 cubic feet. Each infiltration trench provides 254 cubic feet of recharge volume below the lowest outlet. An overflow weir is incorporated into each infiltration trench to safely dissipate flow from large storm events and prevent scour. During the 100 year storm event, peak flows are anticipated to remain less than 1 cfs, indicating that runoff would be captured and released at non-erosive rates[15] even during large storm events. Existing and proposed discharge rates for the Unit Discharge infiltration trench are shown for the 2, 10, and 100 year storm events in Table 4.17-19.

Table 4.17-19 Peak Discharge Rates (cfs[1])–Hockomock Swamp Trestle Unit Discharge

Design Point	2-year	10-year	100-year
Design Point: Wetland			
Existing	0.12	0.28	0.56
Proposed	0.05	0.14	0.26

1 cubic feet per second

[14] HydroCAD Software Solutions LLC. HydroCAD Stormwater Modeling System, Version 7, Owner's Manual. Chocorua, New Hampshire. 2004.

[15] The Massachusetts Stormwater Handbook defines a non-erosive flow velocity for drainage channels to be generally less than five feet per second.

Massachusetts Stormwater Standard 4 specifies that "Stormwater Management Systems shall be designed to remove 80% of the average annual post-construction load of Total Suspended Solids (TSS)." As previously noted, rail operations generate negligible quantities of TSS. Because the trestle consists of ballast placed inside a solid structure, stormwater runoff must be managed differently than that from ballast placed directly on the ground; however the TSS loading would be similarly negligible. Each infiltration trench has been designed to meet the 0.5 inch Water Quality Volume for its contributing drainage area. Because of the trestle's configuration and setting, it is not feasible to provide the full 1 inch Water Quality Volume and the 44 percent pretreatment required to receive credit for 80 percent TSS removal under the guidelines contained in the Stormwater Handbook. However, discharges from the trestle can be considered *de minimis* under the guidance provided in Volume 3, Chapter 1 of the Handbook. The Handbook specifies the following criteria for a *de minimis* determination:

- Physical site conditions preclude installation of a TSS treatment practice.
- The discharge is less than or equal to 1 cfs for runoff associated with the 2 year, 24 hour storm.
- 80 percent TSS removal is achieved on an average weighted basis from the site as a whole using the weighted average method.
- The stormwater outlets where additional controls are used to achieve more than 80 percent TSS removal must discharge to the same reach of the same wetland or waterbody as the outlets that achieve less than 80 percent TSS removal.
- Controls are placed at the outlet to prevent erosion or scour of the wetland/stream channel and bank.
- Standard 2 and Standard 3 must be achieved on a site-wide basis.
- Source control and pollution prevention measures that mitigate the impact of the untreated or partially treated discharges are identified in the Pollution Prevention Plan.
- The size of the drainage area contributing runoff to the untreated outlet has been reduced to the maximum extent practicable.

Compliance with Massachusetts Stormwater Standards

The Hockomock Swamp Trestle has been designed to comply fully with all ten of the Stormwater Standards. Compliance documentation is included in the Hockomock Swamp Stormwater Report (Appendix 4.17-A) and summarized in Table 4.17-20.

Table 4.17-20 Massachusetts Stormwater Standards Compliance[16]–Hockomock Swamp Trestle

Standard	Compliance Level Achieved
Standard 1: No New Untreated Discharges or Erosion to Wetlands	Full compliance would be achieved. BMPs are proposed to treat stormwater runoff from the site and outlets and conveyances are protected from erosion.
Standard 2: Peak Rate Attenuation	Full compliance would be achieved. Peak discharges rates at the design point are expected to be reduced between 0.08 and 0.30 cfs for the range of storm events analyzed.
Standard3: Stormwater Recharge	Full compliance would be achieved. 254 cubic feet of recharge volume is provided within each infiltration trench, exceeding the required recharge volume of 127 cubic feet per unit discharge area.
Standard 4: Water Quality	Full compliance would be achieved. The trestle drainage system meets the *de minimis* requirements for WQV and TSS removal.
Standard 5: Land Uses with Higher Potential Pollutant Loads	Full compliance would be achieved. The trestle does not meet any of the criteria of a LUHPPL.
Standard 6: Critical Areas	Full compliance would be achieved. The site discharges to wetlands within the Hockomock Swamp ACEC, a stormwater critical area.
Standard 7: Redevelopment Standards	Not applicable. This site is not a redevelopment.
Standard 8: Construction Period Pollution Prevention and Erosion and Sedimentation Controls	Full compliance would be achieved. The project would obtain coverage under the NPDES Construction General Permit prior to the start of earthmoving activities.
Standard 9: Operation and Maintenance Plan	Full compliance would be achieved. MassDOT would develop a detailed O&M plan during final design as part of the Notice of Intent submittal.
Standard 10: Prohibition of Illicit Discharges	Full compliance would be achieved. Storm drainage structures remaining from the previous development which are part of the redevelopment area would be removed. The proposed station has been designed so that the components included therein are in full compliance with current standards. No statement is made with regard to the drainage system in portions of the site not included in the redevelopment project area.

Stations

This section describes each train station, indicates its location near any notable surface or groundwater resources, and evaluates the potential direct and indirect impacts to water resources that could result from the construction and operation of each station for the South Coast Rail project. The section includes a discussion of the design elements of the proposed railroad stations that relate to stormwater management and describes the results of the stormwater analyses and potential mitigation measures, as required by the Secretary's Certificate. The Massachusetts Stormwater Standards (the Stormwater Standards) provide a framework for evaluating the impacts of development activities and identifies mitigation measures that are required to offset those impacts. Twelve stations would be constructed or modified as part of the South Coast Rail project. Modifications are proposed at two existing stations

[16] www.mass.gov/dep/water/laws

(Canton Center and Stoughton). The modifications at the Canton Center Station are limited to the construction of a new Americans with Disabilities Act (ADA)-compliant platform and canopy and do not involve the construction of additional impervious area. The existing Stoughton Station would be removed and replaced with a new station at a different location.

New platform-only stations would be constructed at the Easton Village, King's Highway, Whale's Tooth, and Battleship Cove sites. These locations are developed sites with existing parking facilities (King's Highway and Whale's Tooth) or are drop-off facilities without on-site parking (Easton Village, Battleship Cove).

The Fall River Depot Station would be constructed on the site of the former railroad station and would include a structured parking facility that would maintain existing drainage patterns at the site.

The newly constructed stations would discharge stormwater runoff to wetlands and would require compliance with the Stormwater Standards. Two of these stations (Taunton and Raynham Park) would be located on previously developed sites that meet the redevelopment criteria under Standard 7 of the Stormwater Standards. Three stations (North Easton, Taunton Depot, and Freetown) would be located on undeveloped sites that would require full compliance with the Stormwater Standards.

For the hydrologic analysis, each of the five analyzed station sites was divided into one or more drainage areas that contribute runoff to one or more design points. Peak discharge rates were evaluated at these design points under pre- and post-development conditions in order to demonstrate compliance with the Stormwater Standards.

The rainfall-runoff response of each site under existing and proposed conditions was evaluated for storm events with recurrence intervals of 2, 10, and 100 years. Rainfall depths used for this analysis were based on the Natural Resources Conservation Service (NRCS) Type III, 24-hour storm event; they were 3.4, 4.8, and 7.0 inches, respectively. Curve numbers for the pre- and post-development conditions were determined using NRCS TR 55 methodology[17] as provided in HydroCAD. The HydroCAD model is based on the NRCS Technical Release 20 (TR 20) Model for Project Formulation Hydrology. Detailed printouts of the HydroCAD analyses are included in stormwater reports for individual station sites and are provided in Appendix 4.17-B. Drainage areas used in the analyses are summarized below and are fully described in the individual station stormwater reports. A summary of the existing and proposed conditions peak discharge rates is included for each station site.

The closed drainage system for each station was designed for the 25-year storm event, in accordance with the MBTA's requirements. Drainage pipes were sized using Manning's Equation[18] for full-flow capacity and the Rational Method. Additionally, the performance of the system was analyzed using StormCAD,[19] a HEC-22[20] based program. Pipe sizing calculations are included in the individual station stormwater reports provided in Appendix 4.17-B.

[17] US Department of Agriculture Natural Resources Conservation Service Conservation Engineering Division. 1986. Urban Hydrology for Small Watersheds, Technical Release 55

[18] The Mannings equation is an empirical equation that applies to uniform flow in open channels and is a function of the channel velocity, flow area and channel slope.

[19] StormCAD software provides comprehensive modeling for the design and analysis of storm sewer systems. See http://www.bentley.com/en-US/Products/StormCAD/

[20] Hydraulic Engineering Circular 22 Urban Drainage Design Manual FHWA-NHI-10-009

Soil characteristics for the five station sites were assessed according to the National Cooperative Soil Survey (NCSS)[21] and the NRCS. Individual geotechnical investigations were con**d**ucted for each station site. Soil conditions were found to vary considerably between sites, with some sites providing excellent opportunities allow stormwater to infiltrate into the ground and others providing limited to no opportunities for infiltration as the groundwater was already at or near the base of the proposed stormwater BMP. In accordance with the Stormwater Standards identified in Table 4.17-20, above, soil infiltration capacity was evaluated according to the 1982 Rawls Rates.[22] Depth to groundwater was evaluated for each location where infiltration BMPs were proposed in order to confirm that there was sufficient separation from seasonal high groundwater. Lined filtration BMPs were proposed for locations where it was not feasible to achieve the required 2 feet of separation from seasonal high groundwater. Geotechnical reports for each station site are included in the individual station stormwater reports provided in Appendix 4.17-B.

The latest FEMA Flood Insurance Rate Maps (FIRMs) were reviewed for each station site in order to evaluate for potential impacts within the 100 year floodplain. According to the latest maps available from FEMA, none of the station sites are within the 100 year floodplain. A copy of the latest FIRM for each station site is included in the station stormwater reports provided in Appendix 4.17-B.

The Secretary's Certificate on the DEIR and the Stormwater Regulations at 310 CMR 10.05(6)(k) require MassDOT to consider Environmentally Sensitive Site Design (ESSD) and Low Impact Development (LID) design practices. Between the constraints of the essentially fixed elevations of the rail bed and site access road(s), the proposed topography at each station site matches the existing topography to the extent practicable and existing drainage patterns would be maintained. Where necessary, retaining walls were used to minimize impact to wetlands or other sensitive areas. Existing mature vegetation would be preserved and unnecessary impervious areas would be removed. Runoff from existing and proposed impervious areas is disconnected where possible and directed to LID features such as filter strips, grassed swales, and bioretention basins. Infiltration basins were incorporated wherever possible to mimic natural hydrology and to improve groundwater recharge. Structured parking (parking garages) was evaluated as an alternative to at-grade parking in order to reduce the potential area of impervious cover at each station.

The following non-structural water quantity and quality control BMPs to be implemented at station sites:

- **Snow Management:** No snow would be placed in, or directly adjacent to wetland resource areas. As much as possible snow would be allowed to melt on pavement where debris and sand may be deposited and swept up for disposal. Snow melt would enter the stormwater management system where it would receive proper treatment.

- **Spill Prevention:** Spill prevention is achieved with the proper storage and handling of hazardous materials. During construction, this is addressed in the Stormwater Pollution

[21] The National Cooperative Soil Survey (NCSS) is a nationwide partnership of federal, regional, state and local agencies; and private entities and institutions. This partnership works together to cooperatively investigate, inventory, document, classify, interpret, disseminate, and publish information about soils of the United States. NCSS standards are common or shared procedures that enhance technology transfer, data sharing, and communications among soil survey participants.

[22] Rawls, Brakensiek and Saxton, 1982, Estimation of Soil Water Properties, Transactions American Society of Agricultural Engineers 25(5): 1316 - 1320, 1328

Prevention Plan (SWPPP) for Construction Activities that would be prepared prior to the start of construction activities.

- **Source Control:** A comprehensive source control program would be implemented at each station site, which includes regular pavement sweeping, catch basin cleaning, and enclosure and maintenance of all dumpsters, compactors, and loading areas. MBTA would develop a detailed Operations and Maintenance Plan (O&M Plan) during the final design phase of the project and would include it with the Notice of Intent submittal. This plan would address specific maintenance measures that must be performed and the required frequency in order to maintain the stormwater management measures at each station site.

The following structural water quantity and quality control BMPs to be implemented at station sites. Not all BMPs are suitable for each station site.

- **Catch Basins with Sumps and Oil/Debris Traps:** Catch basins at station sites are to be constructed with sumps (minimum 4 feet) and oil/debris traps to prevent the discharge of sediments and floating contaminants. Catch basins must be cleaned regularly to remove accumulated debris and maintain functionality. Catch basins would be inspected and cleaned according to the maintenance schedule laid out in the O&M Plan.

- **Oil/Grit Separator:** MADEP requires the use of a pretreatment BMP, such as an oil/grit separator for sites that constitute land uses with higher potential pollutant loads (LUHPPLs). These structures are underground storage tanks consisting of three chambers that are separated by interior baffle walls. The placement of the interior baffles and the outlet from the structure are designed to remove heavy particulates, floating debris and hydrocarbons from stormwater. Oil/grit separators must be cleaned regularly to remove accumulated debris and maintain functionality. Oil/grit separators would be inspected and cleaned according to the maintenance schedule laid out in the O&M Plan.

- **Vegetated (Grass & Gravel) Filter Strip:** A vegetated or grass filter strip is a linear stormwater management measure that is generally oriented parallel to the contributing drainage area and treats sheet flow or small quantities of concentrated flows that can be distributed along the width of the filter strip. A level spreader, consisting of a pea gravel diaphragm or other similar feature, runs the width of the area being treated. The level spread intercepts and dissipates runoff to minimize the risk of erosion due to concentrated flows. Vegetated filter strips are maintained (mowed) in conjunction with standard site landscape maintenance. Periodic inspections of filter strip are required to confirm that the pea gravel diaphragm has not clogged and that filter strip does not have areas of erosion or bare soil. Additional guidance for filter strip inspection and maintenance requirements would be provided in the O&M Plan.

- **Vegetated (Grass) Swales:** Vegetated swales provide some treatment, reduction, and distribution of stormwater during conveyance. Pollutant removal mechanisms include filtering by the swale vegetation (both on side slopes and on bottom), filtering through a subsoil matrix, and/or infiltration into the underlying soils. Trash removal and vegetation management are required in conjunction with standard landscape maintenance. Additional guidance for vegetated swale inspection and maintenance requirements would be provided in the O&M Plan.

- **Bioretention Swales:** Bioretention swales provide enhanced treatment and infiltration capacity with a conditioned soil mix, mulch layer, and an increased planting density in the conveyance swale. Trash removal and vegetation management are required in conjunction with standard landscape maintenance. Additional guidance for bioretention swale inspection and maintenance requirements would be provided in the O&M Plan.

- **Bioretention Basins:** A bioretention basin manages and treats stormwater runoff using a conditioned planting soil bed and planting materials to filter runoff stored within a shallow depression. The system consists of a flow regulation structure, a pretreatment filter strip or vegetated swale, a sand bed, a shallow ponding area, a surface organic layer of mulch, a planting soil bed, plant material, a gravel underdrain system (if required), and an overflow drain. The vegetation in a bioretention basin serves to filter and transpire runoff—improving water quality and reducing runoff quantity—and the root systems can enhance infiltration. The soil medium filters out pollutants and allows storage and infiltration of stormwater runoff; and the infiltration bed provides additional volume control. Trash removal and vegetation management are required in conjunction with standard landscape maintenance. A bioretention basin should also be inspected periodically during the first year and annually thereafter for sediment buildup, erosion, vegetative conditions. Additional guidance for bioretention basin inspection and maintenance requirements would be provided in the O&M Plan.

- **Infiltration Basin:** Infiltration basins are stormwater runoff impoundments that are constructed in areas with permeable soils. Pretreatment of runoff is critical to prevent the basin from becoming clogged with fine sediment and suffering premature failure. Runoff from the design storm is stored until it exfiltrates through the soil of the basin floor. Trash removal and vegetation management are required in conjunction with standard landscape maintenance. Periodic inspections are required to ensure that the basin drains within 72 hours of the design storm event. If the basin is not draining adequately, a layer of sediment may need to be removed from the floor of the basin to restore infiltration capacity. Additional guidance for infiltration basin inspection and maintenance requirements would be provided in the O&M Plan.

- **Porous Pavement:** Porous pavement is constructed with a base and subbase that allows stormwater to infiltrate through it thereby reducing runoff volume. MassDOT considered permeable pavement but determined that this is not a feasible surface finish because of the lack of ability to maintain the surface and because the amount of sand and salt that would be used during winter operations would clog the system. The MBTA does not currently use porous pavement for these reasons.

Any new or redeveloped station that would increase impervious area at the site would likely require a new or upgraded stormwater management system to prevent flooding or water quality impacts from the construction and operation of the stations. The following section provides a description as measures proposed (if necessary) to comply with MADEP stormwater standards.

Canton Center Station

Canton Center Station is an existing station located in Canton, Massachusetts on the Stoughton Line. The site is fully developed with the existing commuter rail station, a 219 car parking lot, and ancillary

structures. The surrounding parcels are fully developed with commercial and industrial uses. Improvements would be limited to construction of a new canopy and platform, and does not involve the construction of additional impervious area. The conceptual design for Canton Center Station is shown on Figure 4.17-13.

Given the current active status of the Canton Center station in a developed area of Canton, the reconstruction of this station would have no impacts to surface or groundwater resources. No stormwater analysis was conducted for Canton Center Station because improvements at the station result in a negligible increase in impervious area. The station is within the Neponset River watershed which has an approved TMDL for bacteria. It is not anticipated that the proposed relocated platform at Canton Center would increase bacteria loads in the watershed.

Stoughton Station

The existing Stoughton Station would be relocated as part of the South Coast Rail project to eliminate conflicts with traffic in Stoughton Center and to meet regulatory requirements for access. Relocating the station would also support downtown revitalization efforts. The existing Stoughton Station is currently the terminal station on the Stoughton Branch of the MBTA commuter rail service. At the current station location, stopped trains block the nearby Wyman Street at-grade crossing while passengers board and alight the train. The low-level platforms of the current station do not meet Americans with Disabilities Act (ADA) accessibility requirements and must be replaced by a high-level platform.

As described in Chapter 3, four location options were reviewed by MassDOT operations and accessibility departments to select a station location and configuration that meets operational and regulatory requirements and provides benefits to the community at a reasonable cost. Option 3 was selected as the Preferred Alternative. This option would realign the tracks and relocate the station between Morton Street and Brock Street with high level platforms and parking on the west side of the tracks (Figure 4.17-24). It has two means of crossing the tracks (a pedestrian bridge and an at-grade crossing). Approximately 2.5 acres of the existing MBTA station parking lot land east of the tracks would be opened for potential development. It would require acquisition of up to 0.2 acres of residential and 9.6 acres of industrial or commercial properties.

As shown in Figure 4.17-14, the footprint of the relocated Stoughton Station and realigned tracks would comprise approximately 7.5 acres. The station would have ADA compliant platforms (with canopies) on either side of the realigned double tracks, with a pedestrian bridge over the tracks connecting the two platforms. Car parking would be provided on the west side of the tracks; a total of 642 spaces are proposed, comprised of 619 standard spaces, 17 accessible spaces, and 6 drop-off spaces. The entrance to the parking lot would be on the south side, off of Brock Street. Approximately 3.3 acres of new impervious surface would be created; added to the existing 2 acres of impervious surface, there would be a total of 5.3 acres of impervious surface at the relocated station site. The parking lot would be configured to avoid any on-site jurisdictional wetlands. The realigned tracks, new platforms, and new parking lot would occupy land currently used for industrial and commercial purposes; these businesses would be displaced. Land east of the realigned tracks, currently occupied by the existing track alignment and parking areas, would be available for redevelopment.

The station is within the Neponset River watershed which has an approved TMDL for bacteria in the watershed. It is not anticipated that the proposed relocated Stoughton Station would increase bacteria loads in the watershed.

The station would be designed in compliance with Massachusetts Stormwater Standards, using appropriate BMPs to maintain groundwater recharge and reduce the discharge of pollutants. No further stormwater analysis has been completed at this time.

North Easton Station

North Easton Station would be a new station located on the Stoughton Line and would be constructed on an approximately 10.0-acre site in Stoughton and Easton, Massachusetts. The site is bounded by undeveloped land to the north, a wetland to the south, office buildings to the east, and the out-of-service Stoughton Line tracks to the west (Figure 4.17-15a).

Station Description—North Easton Station would include a center platform with canopy, a parking lot with 506 spaces, access driveway, bus drop-off area, sidewalks, stairs and ramps associated with access from the parking lot to the platform, bicycle parking facilities, retaining walls and stormwater infrastructure. Construction of the station would involve clearing and grubbing wooded portions of the site and removing a small paved area that currently exists on the site. Construction of the station and associated parking facility would result in a net increase of approximately 1.8 acres of impervious area. The conceptual design for North Easton Station is shown on Figure 4.17-15b.

Wetland areas are located both north and south of the site, but the limits of work would not affect any waterbodies or drinking water protection areas. Whitman Brook, a certified vernal pool (CVP), and the Zone II area for Easton GP Wells #1, #2, and #4 are located nearby but would not be affected by the station site.

Since the site is largely undeveloped, the addition of parking and the station structures would require a new stormwater management system. A stormwater management area would be provided at the south end of the site to manage stormwater flows, reduce flooding, and remove settleable solids. The stormwater management system would discharge to the wetlands adjacent to the site outside of the Zone II area for the Easton wells. With a proper stormwater management design for the station site, there would be no impacts to surface or groundwater resources such as Whitman Brook, the CVP, or the Zone II.

Stormwater Analysis—For the North Easton Station site, three separate design points were identified and the contributing drainage areas to each were evaluated under existing and proposed conditions. Peak flow reductions were achieved for all storm events through the use of LID techniques and stormwater BMPs. These practices include minimizing disturbance to existing trees and vegetation, infiltration basins, bioretention basins, grassed swales, oil/grit separators, and the use of light colored pavement for sidewalks. The BMPs were sized to manage the water quality volume and recharge volume requirements identified under the Stormwater Standards. The station is within the Taunton River watershed and is subject to the approved TMDL for pathogens in the watershed. It is not anticipated that the proposed improvements at the site would increase bacteria loads in the watershed.

The proposed drainage areas for North Easton Station are shown on Figure 4.17-15b. Stormwater runoff from the northern portion of the site sheet flows off of the impervious surface and is conveyed via a grassed swale to Bioretention Basin 1. Bioretention Basin 1 drains to Wetland ST-10. Stormwater runoff from the southern portion of the site is collected in deep sump hooded catch basins, travels through the closed drainage system, passes through an oil/ grit separator prior to discharging to sediment forebays, and is ultimately discharged to Infiltration Basins 2, 3, 4, and 5. These infiltration basins drain to Wetland EA 1. Wooded areas in the northern portion of the property would be maintained in their existing

conditions as much as possible. Existing and proposed peak discharge rates to each of the design points for the 2, 10, and 100 year storm events are shown in Table 4.17-21.

Table 4.17-21 Peak Discharge Rates (cfs[1])–North Easton Station

Design Point	2-year	10-year	100-year
Design Point 1: Wetland ST-10			
Existing	1.1	2.6	5.5
Proposed	1.0	2.2	4.3
Design Point 3: Wetland EA-1			
Existing	1.2	3.3	9.0
Proposed	0.8	2.8	7.8
Design Point 4: Wetland EA-1			
Existing	1.3	2.2	3.8
Proposed	1.0	1.8	3.0

1 cubic feet per second

Compliance with Massachusetts Stormwater Standards—North Easton Station has been designed to comply fully with all ten of the Stormwater Standards. Compliance documentation is included in the North Easton Station Stormwater Report (Appendix 4.17-B) and summarized in Table 4.17-22.

Table 4.17-22 Massachusetts Stormwater Standards Compliance–North Easton Station

Standard	Compliance Level Achieved
Standard 1: No New Untreated Discharges or Erosion to Wetlands	Full compliance would be achieved. BMPs are proposed to treat stormwater runoff from the site and outlets and conveyances are protected from erosion.
Standard 2: Peak Rate Attenuation	Full compliance would be achieved. Peak discharges rates at each design point are expected to be reduced between 0 and 1.4 cfs for the range of storm events analyzed.
Standard3: Stormwater Recharge	Full compliance would be achieved. The required recharge volume of 6,926 cubic feet is provided in three infiltration basins and a bioretention basin that provide a total of 55,745 cubic feet of recharge.
Standard 4: Water Quality	Full compliance would be achieved. Eighty percent total suspended solids (TSS) removal is achieved for all drainage areas with contributions from impervious surfaces and 44% pretreatment is also provided prior to infiltration BMPs.
Standard 5: Land Uses with Higher Potential Pollutant Loads	Full compliance would be achieved. The station is considered a LUHPPL because it has greater than 500 parking spaces. BMPs have been sized to treat the 1-inch Water Quality Volume and provide 44% pretreatment of TSS prior to infiltration.
Standard 6: Critical Areas	Full compliance would be achieved. The site does not discharge near or to a stormwater critical area.
Standard 7: Redevelopment Standards	Full compliance would be achieved. The site has been designed to fully comply would all ten Stormwater Standards.
Standard 8: Construction Period Pollution Prevention and Erosion and Sedimentation Controls	Full compliance would be achieved. The project would obtain coverage under the NPDES Construction General Permit prior to the start of earthmoving activities.
Standard 9: Operation and Maintenance Plan	Full compliance would be achieved. MassDOT would develop a detailed O&M plan during final design as part of the Notice of Intent submittal.
Standard 10: Prohibition of Illicit Discharges	Full compliance would be achieved. The site was previously undeveloped and no sanitary sewer or storm drainage infrastructure is known to exist on the site. The proposed station has been designed in full compliance with current standards.

Easton Village Station

Easton Village Station would be a new platform-only station located adjacent to the historic Old Colony Railroad Station in North Easton, Massachusetts. The station site is adjacent to the existing paved parking area serving the adjacent Easton Historical Society (housed in the historic station building) and is within the existing ballasted right-of-way (Figure 4.17-16).

Station Description—Easton Village Station would include a side platform with canopy, ancillary landscape improvements, bicycle parking facilities, and utility improvements. No additional parking

spaces would be added, however a second driveway would be added to improve traffic circulation. The conceptual design for Easton Village Station is shown on Figure 4.17-16.

This 0.5 acre site is located on Sullivan Avenue at the transition point to Mechanic Street (near the intersection with Pond Street) in Easton, within walking distance of downtown Easton. The station would be village-style and serve walk-in or bike-in customers. The station includes only 10 parking spaces, which are designated for pick up/drop off only.

The station would be located near Shovelshop Pond and Queset Brook. While the limit of work for the station would not affect Shovelshop Pond, Queset Brook passes beneath the track and platform at the southern end of the station. The station is located within the Zone II area for Easton GP Wells #1, #2, and #4, which are operated by the Easton Water Division. Stormwater from the parking lot would flow to Sullivan Street and would be discharged to Shovelshop Pond. The station would have negligible effects on groundwater recharge and groundwater quality, due to the existing development in this area, the minimal increase in impervious area, and the lack of pollutant sources at the station itself, which is only a platform with minimal parking. Groundwater impacts are not anticipated, and, with proper design of the station, there would be no impacts to surface or groundwater resources, including Shovelshop Pond.

Stormwater Analysis—No stormwater analysis was conducted for Easton Village Station because improvements at the station result in a negligible increase in impervious area. The station is within the Taunton River watershed and is subject to the approved TMDL for pathogens in the watershed. It is not anticipated that the proposed improvements at the site would increase bacteria loads in the watershed.

Compliance with Massachusetts Stormwater Standards—Improvements at the Easton Village Station result in a negligible increase in impervious area and would be designed to comply with all ten of the Stormwater Standards to the maximum extent practicable.

Raynham Park Station

Raynham Park Station would be a new station located on the Stoughton Line and would be constructed on an 11.4 acre site south of the former Raynham Park Greyhound Track in Raynham, Massachusetts (Figure 4.17-17a). The site consists almost entirely of previously developed land and is bounded to the north by the former Raynham Park Greyhound Track, to the south by industrial buildings, to the east by Route 138, and the Stoughton Line right-of-way and the Hockomock Swamp Area of Critical Environmental Concern (ACEC) to the west. Drainage from the site discharges to the Hockomock Swamp ACEC, either directly through surface channels or through the closed drainage system of the adjacent parking lot.

Station Description—Raynham Park Station would include a center platform with canopy, ancillary landscape improvements, a parking lot with 432 spaces, bicycle parking facilities, and utility improvements. Construction of the station would involve demolishing abandoned kennels and several small buildings currently on the site. Improvements at the site would reduce impervious area by 0.5 acres. The conceptual design for Raynham Park Station is shown on Figure 4.17-17a.

The limits of work would not affect any waterbodies or drinking water protection areas. The proposed station layout includes a subsurface detention and infiltration system to manage stormwater flows, reduce flooding, and remove settleable solids. The stormwater system would discharge to an unnamed perennial stream within the Hockomock Swamp ACEC. The use of an infiltration-based system would

provide a high level of settling and filtration of any contaminants. With a proper stormwater management design for the station site, there would be no impacts to surface or groundwater resources, including the Hockomock Swamp.

Stormwater Analysis—For the Raynham Park Station site, four separate design points were identified and the contributing drainage areas to each were evaluated under existing and proposed conditions. Peak flow reductions were achieved for all storm events through the reduction of impervious area and the use of LID techniques and stormwater BMPs such as gravel and grass filter strips, grassed channels, bioretention basins, and a bioretention swale. The BMPs were sized to manage the water quality volume and recharge volume requirements identified under the Stormwater Standards. The station is within the Taunton River watershed and is subject to the approved TMDL for pathogens in the watershed. It is not anticipated that the proposed improvements at the site would increase bacteria loads in the watershed.

The proposed drainage areas for Raynham Park Station are shown on Figure 4.17-17b. Stormwater runoff from the northeastern portion of the site sheet flows off of the impervious surface and is conveyed via two grassed swales to Bioretention Basin 1. Overflows from this basin are discharged to the existing paved parking areas farther north and are captured by the existing closed drainage system in this portion of the site, as under existing conditions. Runoff from the landscaped area at the southeast portion of the site would sheet flow to Wetland R5. Runoff from the northwest portion of the site would be collected in a new closed drainage system that would discharge to Bioretention Basin 3. Overflows from this basin are discharged to the existing paved parking areas farther north and are captured by the existing closed drainage system in this portion of the site, as under existing conditions. The southwest portion of the site is drained by sheet flow to a gravel and grass filter strip and into a bioretention swale before discharging to an unnamed perennial stream west of the rail line. This stream flows north into the Hockomock Swamp ACEC. Existing and proposed peak discharge rates to each of the design points for the 2, 10, and 100 year storm events are shown in Table 4.17-23.

Compliance with Massachusetts Stormwater Standards—Raynham Park Station has been designed to comply fully with all ten of the Stormwater Standards. Compliance documentation is included in the Raynham Park Station Stormwater Report (Appendix 4.17-B) and summarized in Table 4.17-24.

Table 4.17-23 Peak Discharge Rates (cfs[1])–Raynham Park Station

Design Point	2-year	10-year	100-year
Design Point 1: Adjacent Parking Area			
Existing	21.8	31.1	45.7
Proposed	16.9	27.6	41.0
Design Point 2: Wetland R5			
Existing	5.3	7.8	11.6
Proposed	3.1	5.5	9.5
Design Point 3: Adjacent Parking Area/Drainage System			
Existing	15.8	23.2	34.7

Proposed	4.9	9.6	15.8

1 cubic feet per second

Table 4.17-24 Stormwater Standards Compliance–Raynham Park Station

Standard	Compliance Level Achieved
Standard 1: No New Untreated Discharges or Erosion to Wetlands	Full compliance would be achieved. BMPs are proposed to treat stormwater runoff from the site and outlets and conveyances are protected from erosion.
Standard 2: Peak Rate Attenuation	Full compliance would be achieved. Peak discharges rates at each design point are expected to be reduced between 0.5 and 9.3 cfs for the range of storm events analyzed.
Standard3: Stormwater Recharge	Full compliance would be achieved. The required recharge volume of 5,289 cubic feet is managed within one of the bioretention areas.
Standard 4: Water Quality	Full compliance would be achieved. Ninety percent TSS removal is achieved for all drainage areas with contributions from impervious surfaces.
Standard 5: Land Uses with Higher Potential Pollutant Loads	Full compliance would be achieved. The station does not qualify as a LUHPPL because it has fewer than 500 parking spaces and does not reach the 1,000 vehicle trip per day threshold.
Standard 6: Critical Areas	Full compliance would be achieved. Because of the proximity to the Hockomock Swamp ACEC, BMPs on the site have been designed to treat the 1-inch water quality volume and meet the 44% pretreatment criteria for infiltration practices.
Standard 7: Redevelopment Standards	Full compliance would be achieved. Although this site constitutes redevelopment, it would fully comply with all ten Stormwater Standards.
Standard 8: Construction Period Pollution Prevention and Erosion and Sedimentation Controls	Full compliance would be achieved. The project would obtain coverage under the NPDES Construction General Permit prior to the start of earthmoving activities.
Standard 9: Operation and Maintenance Plan	Full compliance would be achieved. MassDOT would develop a detailed O&M plan during final design as part of the Notice of Intent submittal.
Standard 10: Prohibition of Illicit Discharges	Full compliance would be achieved. Storm drainage structures remaining from the previous development which are part of the redevelopment area would be removed. The proposed station has been designed so that the components included therein are in full compliance with current standards. No statement is made with regard to the drainage system in portions of the site not included in the redevelopment project area.

Taunton Station

Taunton Station would be a new station constructed on an 11.9 acre brownfield site located at the intersection of East Arlington Street and William Hooke Lane in Taunton, Massachusetts near the Taunton River (Figure 4.17-18a). The site is bounded by undeveloped land to the north, Arlington Street to the south, a wetland to the west, and an active segment of Stoughton Line tracks to the east. The remnant development at the site consists of building foundations and paved driveways left after the previous structures on the site burned down.

Station Description—Taunton Station would include a side platform with canopy, a parking lot with 210 spaces, access driveway, bus drop off area, sidewalks, stairs and ramps associated with access from the parking lot to the train platform, bicycle parking facilities, and a bioretention basin. Ancillary landscape improvements would be made across the site, including the removal of the existing concrete building pads and existing broken pavement. Improvements at the station site would reduce impervious area by 2.8 acres. The conceptual station design for Taunton Station is shown on Figure 4.17-18a.

The limits of work would not affect any waterbodies or drinking water protection areas. An unnamed stream flows through a wetland west of the site and the Taunton River to southeast of the site, but neither is within the limits of work. Given that the site is a previously-developed brownfield site, its redevelopment would be expected to reduce the potential for stormwater and groundwater pollution by removing or remediating existing contamination. With proper handling of existing contamination and a thorough stormwater management design, there would be no adverse impacts to the stream or any other surface or groundwater resources.

Stormwater Analysis—For the Taunton Station site, a single design point was identified and the contributing drainage areas to this design point were evaluated under existing and proposed conditions. Peak flow reductions were achieved for all storm events through the reduction of impervious area and the use of LID techniques and stormwater BMPs such as a grassed channels and bioretention basin. These BMPs were sized to manage the water quality volume and recharge volume requirements identified under the Stormwater Standards. The site is within the Taunton River watershed and is subject to the approved TMDL for pathogens in the watershed. It is not anticipated that the proposed commuter rail station would increase bacteria loads in the watershed.

The proposed drainage areas for Taunton Station are shown on Figure 4.17-18b. Under existing conditions, stormwater sheet flows untreated from impervious surfaces to Wetland T41. Stormwater from the proposed impervious surfaces would sheet flow into a grassed swale and then be conveyed to Bioretention Basin 1 for treatment. Discharge from this basin and from vegetated portions of the site would flow to Wetland T41. A significant reduction in impervious area would decrease runoff and increase recharge from the site. Existing and proposed peak discharge rates to the design point are shown for the 2, 10, and 100 year storm events in Table 4.17-25.

Table 4.17-25 Peak Discharge Rates (cfs[1])–Taunton Station

Design Point	2-year	10-year	100-year
Design Point: Wetland T41			
Existing	19.1	28.4	42.8
Proposed	13.9	23.0	37.1

1 cubic feet per second

Compliance with Massachusetts Stormwater Standards—Taunton Station has been designed to comply fully with all ten of the Stormwater Standards. Compliance documentation is included in the Taunton Station Stormwater Report (Appendix 4.17-B) and summarized in Table 4.17-26.

Table 4.17-26 Stormwater Standards Compliance–Taunton Station

Standard	Compliance Level Achieved
Standard 1: No New Untreated Discharges or Erosion to Wetlands	Full compliance would be achieved. BMPs are proposed to treat stormwater runoff from the site and outlets and conveyances are protected from erosion.
Standard 2: Peak Rate Attenuation	Full compliance would be achieved. Peak discharges rates at the design point are expected to be reduced between 5.2 and 5.7 cfs for the range of storm events analyzed.
Standard3: Stormwater Recharge	Full compliance would be achieved. 1,263 cubic feet of recharge volume is provided within the bioretention area, exceeding the required recharge volume of 970 cubic feet.
Standard 4: Water Quality	Full compliance would be achieved. Ninety percent TSS removal is achieved for all drainage areas with contributions from impervious surfaces.
Standard 5: Land Uses with Higher Potential Pollutant Loads	Full compliance would be achieved. The station does not qualify as a LUHPPL because it has fewer than 500 parking spaces and does not reach the 1,000 vehicle trip per day threshold.
Standard 6: Critical Areas	Full compliance would be achieved. The site does not discharge near or to a critical area.
Standard 7: Redevelopment Standards	Full compliance would be achieved. Although this site constitutes redevelopment, it would fully comply with all ten Stormwater Standards.
Standard 8: Construction Period Pollution Prevention and Erosion and Sedimentation Controls	Full compliance would be achieved. The project would obtain coverage under the NPDES Construction General Permit prior to the start of earthmoving activities.
Standard 9: Operation and Maintenance Plan	Full compliance would be achieved. MassDOT would develop a detailed O&M plan during final design as part of the Notice of Intent submittal.
Standard 10: Prohibition of Illicit Discharges	Full compliance would be achieved. Storm drainage structures remaining from the previous development which are part of the redevelopment area would be removed. The proposed station has been designed so that the components included therein are in full compliance with current standards. No statement is made with regard to the drainage system in portions of the site not included in the redevelopment project area.

Taunton Depot Station

Taunton Depot Station would be a new station located on the New Bedford Main Line and would be constructed on a 13-acre site located at Taunton Depot Drive in Taunton, Massachusetts (Figure 4.17-19a). The site is west of the Taunton Depot Shopping Center and is bound by retail buildings to the east and by vegetated wetlands to the south, west, and north. The active New Bedford Main Line tracks are beyond the wetlands west of the site. An existing detention basin associated with the shopping center drainage system is located immediately southeast of the site.

Station Description—Taunton Depot Station would include a center platform with canopy, ancillary landscape improvements, a parking lot with 398 spaces, a pickup/drop off area, bicycle parking facilities,

and utility improvements. A sidewalk that connects the station to the existing sidewalk on Taunton Depot Drive and to the Taunton Gardens apartment complex would be constructed. Improvements at the station site would increase the impervious area by 3.3 acres. The conceptual design for Taunton Depot Station is shown on Figure 4.17-19a.

The existing grading directs stormwater runoff into wetland areas adjacent to the site and the right-of-way. A wetland area containing an unnamed stream would be crossed by the proposed platform access from the parking area. The limits of work would not intersect any named waterbodies or drinking water protection areas. The station site is located in a developed area with existing roads and neighborhoods however; the station facility would introduce new uses and stormwater discharges to the area. The additional pavement and parking would require a stormwater management system to prevent impacts to receiving waters. Treated stormwater would discharge to wetlands adjacent to the site. With proper design of the drainage system, there would be no impacts to surface or groundwater resources.

Stormwater Analysis—For the Taunton Depot Station site, two separate design points were identified and the contributing drainage areas to each were evaluated under existing and proposed conditions. Peak flow reductions were achieved for all storm events through the use of LID techniques and stormwater BMPs such as bioretention basins, a grassed swale, and the use of light colored pavement for sidewalks. The BMPs were sized to manage the water quality volume and recharge volume requirements identified under the Stormwater Standards. The station is within the Taunton River watershed and is subject to the approved TMDL for pathogens in the watershed. It is not anticipated that the proposed commuter rail station would increase bacteria loads in the watershed.

The proposed drainage areas for Taunton Depot Station are shown on Figure 4.17-19b. Stormwater runoff from the northern portion of the site sheet flows off of the impervious surface and into Bioretention Basin 1. Bioretention Basin 1 drains to Wetland 1. Stormwater runoff from the southern portion of the site sheet flows off of the impervious surface and into Bioretention Basin 2. Bioretention Basin 2 drains to Wetland 1. Stormwater runoff from the driveway and eastern portion of the site drains to Bioretention Basin 3. Bioretention Basin 3 drains to Wetland 3. Runoff from the northern perimeter of the site is captured in a vegetated swale that discharges to Wetland 1. Runoff from the vegetated southern perimeter of the site sheet flows to Wetland 3. Existing and proposed peak discharge rates to each of the design points for the 2, 10, and 100 year storm events are shown in Table 4.17-27.

Table 4.17-27 Peak Discharge Rates (cfs[1])–Taunton Depot Station

Design Point	2-year	10-year	100-year
Design Point 1: Wetland 1			
Existing	3.1	7.2	15.2
Proposed	3.0	5.3	10.9
Design Point 2: Wetland 3			
Existing	0.5	1.3	3.0
Proposed	0.4	1.0	2.9

1 cubic feet per second

Compliance with Massachusetts Stormwater Standards—Taunton Depot Station has been designed to comply fully with all ten of the Stormwater Standards. Compliance documentation is included in the Taunton Depot Station Stormwater Report (Appendix 4.17-B) and summarized in Table 4.17-28.

Table 4.17-28 Massachusetts Stormwater Standards Compliance–Taunton Depot Station

Standard	Compliance Level Achieved
Standard 1: No New Untreated Discharges or Erosion to Wetlands	Full compliance would be achieved. BMPs are proposed to treat stormwater runoff from the site and outlets and conveyances are protected from erosion.
Standard 2: Peak Rate Attenuation	Full compliance would be achieved. Peak discharges rates at the design points are expected to be reduced between 0.1 and 4.3 cfs for the range of storm events analyzed.
Standard3: Stormwater Recharge	Full compliance achieved. The required recharge volume of 4,071 cubic feet is managed within the bioretention basins. Because of high groundwater, these basins must be lined and underdrained. Approximately 21,000 cubic feet of volume is provided in the basins and filtered through the soil media before being intercepted by an underdrain and discharged to the adjacent wetland.
Standard 4: Water Quality	Full compliance would be achieved. Eighty percent TSS removal is achieved for all drainage areas with contributions from impervious surfaces.
Standard 5: Land Uses with Higher Potential Pollutant Loads	Full compliance would be achieved. The station does not qualify as a LUHPPL because it has fewer than 500 parking spaces and does not reach the 1,000 vehicle trip per day threshold.
Standard 6: Critical Areas	Full compliance would be achieved. The site does not discharge near or to a critical area.
Standard 7: Redevelopment Standards	Not applicable. This site is not a redevelopment.
Standard 8: Construction Period Pollution Prevention and Erosion and Sedimentation Controls	Full compliance would be achieved. The project would obtain coverage under the NPDES Construction General Permit prior to the start of earthmoving activities.
Standard 9: Operation and Maintenance Plan	Full compliance would be achieved. MassDOT would develop a detailed O&M plan during final design as part of the Notice of Intent submittal.
Standard 10: Prohibition of Illicit Discharges	Full compliance would be achieved. The site was previously undeveloped and no sanitary sewer or storm drainage infrastructure is known to exist on the site. The proposed station has been designed in full compliance with current standards.

Freetown Station

Freetown Station would be a new station located on the existing Fall River Secondary and would be constructed on an approximately 7 acre site located on South Main Street in Freetown, Massachusetts (Figure 4.17-20a). The site is bounded by woods and wetland to the north and southwest, grassed pasture to the northeast, the Fall River Secondary to the southeast, commercial development to the west, and by South Main Street to the northwest. A portion of this station site is within the Coastal Zone. Compliance with the Coastal Zone Management Regulations is described in Chapter 4.18, *Coastal Zone Management and Chapter 91*.

Station Description—Freetown Station would include a side platform with canopy, ancillary landscape improvements, a parking lot with 173 spaces, a pickup/drop off area, bicycle parking facilities, and utility

improvements. Improvements at the site would increase impervious area by 2.4 acres. The conceptual design for Freetown Station is shown on Figure 4.17-20a.

The site is partially surrounded by wetland areas, including an unnamed stream on the northeast edge and another unnamed stream on the southwest edge. However, the limits of work would not intersect any named waterbodies or drinking water protection areas.

Given that this portion of the site is undeveloped, a new stormwater drainage system would be required. A stormwater management area would be included at the west end of the site to treat and manage stormwater flows from the west portion of the parking lot. This stormwater management area would discharge to the wetland southwest of the site. A second and third management area would be included at the northeast portion of the site to treat and manage stormwater flows from the entrance roadways and east portion of the parking lot. These stormwater management areas would discharge to the wetland north of the site. With proper design of the stormwater management system, there would be no impacts to surface or groundwater resources.

Stormwater Analysis—For the Freetown Station site, one design point was identified and the contributing drainage areas to that design point were evaluated under existing and proposed conditions. Peak flow reductions were achieved for all storm events through the use of LID techniques and stormwater BMPs such as minimizing disturbance to existing trees and vegetation, infiltration basins, grassed swales, and the use of light colored pavement for sidewalks. The BMPs were sized to manage the water quality volume and recharge volume requirements identified under the Stormwater Standards. The station is within the Taunton River watershed and is subject to the approved TMDL for pathogens in the watershed. It is not anticipated that the proposed commuter rail station would increase bacteria loads in the watershed.

The proposed drainage areas for Freetown Station are shown on Figure 4.17-20b. Stormwater runoff from the northern portion of the site sheet flows off of the impervious surface and into Infiltration Basin 1. Infiltration Basin 1 drains to Wetland 1. Stormwater runoff from the southern portion of the site sheet flows off of the impervious surface and into Infiltration Basin 2. Infiltration Basin 2 drains to Wetland 1. Stormwater runoff from the driveway and eastern portion of the site drains to Infiltration Basin 3. Infiltration Basin 3 drains to Wetland 3. Runoff from the northern perimeter of the site is captured in a vegetated swale that discharges to Wetland 1. Runoff from the vegetated southern perimeter of the site sheet flows to Wetland 3. Existing and proposed peak discharge rates to each of the design points for the 2, 10, and 100 year storm events are shown in Table 4.17-29.

Table 4.17-29 Peak Discharge Rates (cfs[1])–Freetown Station

Design Point	2-year	10-year	100-year
Design Point 1: Wetland 1			
Existing	10.8	18.3	33.4
Proposed	10.4	17.3	31.8

1 cubic feet per second

Compliance with Massachusetts Stormwater Standards—Freetown Station has been designed to comply fully with all ten of the Stormwater Standards. Compliance documentation is included in the Freetown Station Stormwater Report (Appendix 4.17-B) and summarized in Table 4.17-30.

Table 4.17-30 Massachusetts Stormwater Standards Compliance–Freetown Station

Standard	Compliance Level Achieved
Standard 1: No New Untreated Discharges or Erosion to Wetlands	Full compliance would be achieved. BMPs are proposed to treat stormwater runoff from the site and outlets and conveyances are protected from erosion.
Standard 2: Peak Rate Attenuation	Full compliance would be achieved. Peak discharges rates at the design point are expected to be reduced between 0.4 and 1.6 cfs for the range of storm events analyzed.
Standard 3: Stormwater Recharge	Full compliance would be achieved. Approximately 8,600 cubic feet of volume is provided in the infiltration basins, exceeding the required recharge volume of 4,676 cubic feet.
Standard 4: Water Quality	Full compliance would be achieved. Eighty percent TSS removal is achieved for all drainage areas with contributions from impervious surfaces.
Standard 5: Land Uses with Higher Potential Pollutant Loads	Full compliance would be achieved. The station does not qualify as a LUHPPL because it has fewer than 500 parking spaces and does not reach the 1,000 vehicle trip per day threshold.
Standard 6: Critical Areas	Full compliance would be achieved. The site does not discharge near or to a critical area.
Standard 7: Redevelopment Standards	Not applicable. This site is not a redevelopment.
Standard 8: Construction Period Pollution Prevention and Erosion and Sedimentation Controls	Full compliance would be achieved. The project would obtain coverage under the NPDES Construction General Permit prior to the start of earthmoving activities.
Standard 9: Operation and Maintenance Plan	Full compliance would be achieved. MassDOT would develop a detailed O&M plan during final design as part of the Notice of Intent submittal.
Standard 10: Prohibition of Illicit Discharges	Full compliance would be achieved. The site was previously undeveloped and no sanitary sewer or storm drainage infrastructure is known to exist on the site. The proposed station has been designed in full compliance with current standards.

Fall River Depot Station

Fall River Depot Station would be a new station located on the existing Fall River Secondary and would be constructed on an approximately 7 acre site on North Davol Street in Fall River, Massachusetts (Figure 4.17-21). The site is bounded by North Davol Street to the west, Pearce Street to the north, Turner Street to the south, and the Fall River Secondary to the east. A portion of the station site is within the Coastal Zone. Compliance with the Coastal Zone Management Regulations is described in Chapter 4.18, *Coastal Zone Management and Chapter 91*.

Station Description—Fall River Depot Station would include a side platform with canopy, a parking lot with 524 spaces in a structured parking facility, bicycle parking facilities, a bus way, and utility improvements. Construction of the station would involve demolishing several commercial and industrial buildings that currently exist on the site. Because the site is completely covered by pavement or buildings under existing conditions, the improvements would result in no change to the amount of

impervious area at the site. The conceptual design for Fall River Depot Station is shown on Figure 4.17-21.

This site was previously developed as a historic train station and subsequent industrial uses. The new station is envisioned to be a multi-modal transportation center with new mixed-use development and parking facilities. Under the Build Alternatives, the station would include approximately 534 parking spaces in a garage. Drainage inside the garage would discharge to the sanitary sewer as required by health codes, while outdoor stormwater would be discharged to the municipal stormwater system. The limits of work would not affect any waterbodies or drinking water protection areas.

Given the existing industrial character of the local waterfront and the other highways and parking areas nearby, the station would not be expected to increase the potential for water pollution. Existing peak flows into the municipal stormwater system would be maintained through the sizing of the closed drainage system and, if necessary, by the addition of subsurface detention chambers. With a stormwater design to prevent flooding and remove suspended solids, there would be no impacts to the local stormwater system or to surface or groundwater resources.

Stormwater Analysis—The reconstruction of Fall River Depot Station would occur within the existing footprint of a previously developed site and would constitute redevelopment. Under existing and proposed conditions, drainage from the site flows to the municipal separate storm sewer system. No wetland resources are present on the site and no construction is proposed within any water bodies or drinking water protection areas. In accordance with NPDES requirements, stormwater runoff from the lower level of the parking garage would be treated in an oil/grit separator and would be drained to the sanitary sewer system. The station is within the Taunton River watershed and is subject to the approved TMDL for pathogens in the watershed. It is not anticipated that the proposed improvements at the site would increase bacteria loads in the watershed.

Compliance with Massachusetts Stormwater Standards—Fall River Depot Station would be designed to comply with all ten of the Stormwater Standards to the maximum extent practicable.

Battleship Cove Station

Battleship Cove Station would be a new station on the existing Fall River Secondary and would be constructed at the existing Gates of Ponta Delgada monument on Water Street in Fall River, Massachusetts. The site is bounded by a commercial and industrial complex to the north, the Fall River Secondary to the east, Firestone Pond to the south, and the Ponta Delgada monument to the west. A portion of this station site is within the Coastal Zone. Compliance with the Coastal Zone Management Regulations is described in Chapter 4.18, *Coastal Zone Management and Chapter 91*.

Station Description—Improvements at Battleship Cove Station are limited to a side platform with canopy, construction of access walkways, stairs and ramps associated with access from the existing monument to the platform, bicycle parking facilities, and landscape retaining walls. No additional parking or other impervious areas would be created. The conceptual design for Battleship Cove Station is shown on Figure 4.17-22.

The Battleship Cove station site would not require development of an undeveloped area, which greatly reduces the net increase in impervious area and any potential for water resource impacts. The closest waterbodies are Firestone Pond and a pond east of the station, sometimes referred to as Crab Pond, which is fed by an unnamed stream that flows under the railroad right-of-way behind the station.

Firestone Pond is located across Water Street from the site but would not be affected by the new station. Crab Pond would be adjacent to the new platform but would not have any long-term impacts from the operation of the station. There would be no direct stormwater discharges to these ponds. Stormwater runoff from the station site would drain into the municipal stormwater system on Water Street. Potential drainage upgrades, if required for the final design, would be coordinated with the City of Fall River. Given the nature of the proposed use, the station would have no impacts to surface or groundwater resources.

Stormwater Analysis—No stormwater analysis was conducted for Battleship Cove Station because the proposed platform would result in a negligible increase in impervious area. The station is within the Taunton River watershed and is subject to the approved TMDL for pathogens in the watershed. It is not anticipated that the proposed platform construction would increase bacteria loads in the watershed.

Compliance with Massachusetts Stormwater Standards—The proposed platform at Battleship Cove Station would result in a negligible increase in impervious area and would be designed to comply with all ten of the Stormwater Standards to the maximum extent practicable.

King's Highway Station

King's Highway Station would be a new commuter rail station that would occupy part of an approximately 55 acre site that is now a shopping plaza with a large bituminous asphalt paved parking lot. The existing New Bedford Main Line runs along the eastern boundary of the existing parking lot.

Station Description—Construction of the new station would be limited to construction of an elevated platform and canopy within the existing right-of-way and a sidewalk to connect the platform and off-site walkways. The conceptual design for King's Highway Station is shown on Figure 4.17-23.

The station would include approximately 360 existing shared parking spaces. The King's Highway station site would reuse a developed area and would cause no net increase in impervious area. Since there would be no increase in impervious area and no change in use, there would be no modifications required to the stormwater drainage system and no impacts to water resources. The limits of work would not affect any waterbodies or drinking water protection areas. No impacts are anticipated to any surface or groundwater resources.

Stormwater Analysis—No stormwater analysis was conducted for King's Highway Station because improvements at the station result in a negligible increase in impervious area. The station is within the Buzzards Bay watershed and is subject to the approved TMDL for pathogens in the watershed. It is not anticipated that the proposed platform would increase bacteria loads in the watershed.

Compliance with Massachusetts Stormwater Standards—Improvements at the King's Highway Station result in a negligible increase in impervious area and would be designed to comply with all ten of the Stormwater Standards to the maximum extent practicable.

Whale's Tooth Station

Whale's Tooth Station would be a new commuter rail station at the existing 14-acre Whale's Tooth parking lot on Acushnet Avenue in New Bedford, Massachusetts. The station would be constructed adjacent to an existing parking lot constructed by the City of New Bedford. The site is bounded to the north by commercial and industrial buildings, to the east by the New Bedford Main Line, and to the

south and west by Acushnet Avenue (Figure 4.17-24). A portion of this station site is within the Coastal Zone. Compliance with the Coastal Zone Management Regulations is described in Chapter 4.18, *Coastal Zone Management and Chapter 91*.

Station Description—Construction of the new station would be limited to construction of an elevated platform and canopy. Because the site is completely covered by pavement or ballast under existing conditions, the improvements would result in a negligible change to the amount of impervious area at the site. The conceptual design for Whale's Tooth Station is shown on Figure 4.17-24.

The limits of work would not affect any waterbodies or drinking water protection areas. New Bedford Harbor is east of the site and is separated from the site by existing industrial development. Given the existing industrial character of the local waterfront and the benign nature of the proposed use, the station would not be expected to increase the potential for water pollution. The existing parking lot has an underground drainage system that discharges near the tracks. This drainage system would remain in place for the station and may not require any upgrades to provide effective stormwater management, as the site improvements would occur almost entirely within the existing built footprint. No impacts are expected to surface or groundwater resources.

Stormwater Analysis—The Whale's Tooth Station would be constructed within the existing footprint of a previously developed site and would constitute redevelopment. Under existing and proposed conditions, drainage from the site flows to the municipal separate storm sewer system. No wetland resources are present on the site and no construction is proposed within any water bodies or drinking water protection areas. The station is within the Buzzards Bay watershed and is subject to the approved TMDL for pathogens in the watershed. It is not anticipated that the proposed platform would increase bacteria loads in the watershed.

Compliance with Massachusetts Stormwater Standards—Whale's Tooth Station would be designed to comply with all ten of the Stormwater Standards to the maximum extent practicable.

Dana Street Station

The DEIS/DEIR included a station in downtown Taunton that would serve the Whittenton Alternative (and the Attleboro Alternative, which has been dismissed from further consideration). The downtown Taunton Station site is no longer available, having been developed as a residential property in the interim. MassDOT reviewed other potential station locations along the Whittenton Branch and the short segment of the Attleboro Secondary that would be used for the Whittenton Alternative. A vacant site along the Attleboro Secondary just south of the Danforth Street at-grade crossing, within walking distance of downtown Taunton, has been selected. The station would be on the east side of the railroad, between the alignment and Dana Street, and would be identified as the Dana Street Station.

Dana Street Station (Figure 4.17-25) would serve walk-in, bike-in, and drive-in customers with 477 parking spaces. Space has been reserved for basins and drainage may tie in to the municipal system. The station would be designed in compliance with Massachusetts Stormwater Standards, using appropriate Best Management Practices (BMPs) to maintain groundwater recharge and reduce the discharge of pollutants. No further stormwater analysis has been completed at this time.

Station Summary

With the exception of Stoughton Station and Dana Street Station, stormwater management systems at each of the new stations have been designed to comply fully with the Stormwater Standards and the Clean Water Act.

Table 4.17-31 summarizes key stormwater information related to the station sites. Four of the proposed stations would consist of platforms only, and would result in a negligible increase in stormwater runoff. These platforms would all be within the existing railbed and are considered redevelopment. Seven new stations are proposed which would consist of parking lots and platforms. Fall River Depot Station would use a parking structure rather than at-grade parking. Two of the stations (Taunton and Raynham Park) would be redevelopment of previously disturbed, mostly paved, sites. The remaining three stations (North Easton, Taunton Depot, and Freetown) would be constructed in undeveloped vegetated areas. All of the stations would incorporate the appropriate BMPs and would fully comply with the Stormwater Standards.

Table 4.17-31 Station Site Summary

Station	Proposed Construction	Existing or Proposed Station	Meets Redevelopment Criteria	Discharge Location or Receiving Waterbody	Within TMDL Watershed	Change in Impervious Area (ac)[6]
Canton[1]	Relocated Platform	Existing	Yes	MS4	Yes[3]	-
North Easton	Platform & Parking	Proposed	No	Wetlands	Yes[4]	+1.8
Easton Village[1]	Platform Only	Proposed	Yes	Queset Brook	Yes[4]	-
Raynham Park	Platform & Parking	Proposed	Yes	Hockomock Swamp	Yes[4]	- 0.5
Taunton	Platform & Parking	Proposed	Yes	Wetland	Yes[4]	-2.8
Taunton Depot	Platform & Parking	Proposed	No	Wetland	Yes[4]	+3.3
Freetown	Platform & Parking	Proposed	No	Wetland	Yes[4]	+2.4
Fall River	Platform & Structured Parking	Proposed	Yes	MS4	Yes[4]	-
Battleship Cove[1]	Platform Only	Proposed	Yes	Wetland	Yes[4]	-
King's Highway[1]	Platform Only	Proposed	Yes	Wetland	Yes[5]	-
Whale's Tooth[1]	Platform Only	Proposed	Yes	MS4	Yes[5]	-

1 Construction/Reconstruction of platforms and canopy only.

Layover Facilities

Two new overnight layover facilities are proposed as part of the South Coast Rail project. These facilities are proposed near the southern terminus of the New Bedford Main Line (Wamsutta) and the southern terminus of the Fall River Secondary (Weaver's Cove East). The facilities are necessary to provide locations for train sets to be stored overnight, for train crews board the train at the start of each shift, and for minor maintenance activities to be performed to the trains.

Both proposed layover facilities would be located on previously developed sites and qualify under the Stormwater Standards as redevelopment. The stormwater management features at both layover facilities were evaluated for compliance with state and federal stormwater regulations and with the requirements of the Secretary's Certificate. As previously stated, railroad layover facilities are considered a LUHPPL as defined in 310 CMR 10.04 and 314 CMR 9.02. As a result, certain BMPs are required to prevent contamination of local wetlands and water resources such as the New Bedford Inner Harbor or the Taunton River. The storage tracks would have drip pans (collection trays) to catch any incidental drips, leaks, or spills of hazardous materials that may occur during storage or maintenance. The drip pans would be connected to an oil/grit separator that would separate petroleum products from stormwater runoff prior to discharge, protecting wetland and water resources from contamination. Any oil or other hazardous materials stored at the site would be secured with secondary containment structures to catch any spills. With the proposed containment measures in place, neither layover facility would pose a significant risk to surface or groundwater resources.

For the hydrologic analysis of the Weaver's Cove East Layover Facility, the site was divided into several drainage areas that contribute runoff to one or more design points. Peak discharge rates were evaluated at these design points under pre- and post-development conditions in order to demonstrate compliance with the Stormwater Standards.

The rainfall-runoff response of this site under existing and proposed conditions was evaluated for storm events with recurrence intervals of 2, 10, and 100 years. Rainfall depths used for this analysis were based on the NRCS Type III, 24-hour storm event; they were 3.4, 4.8, and 7.0 inches, respectively. Curve numbers for the pre- and post-development conditions were determined using NRCS TR 55 methodology as provided in HydroCAD. The HydroCAD model is based on the NRCS TR 20 Model for Project Formulation Hydrology. Detailed printouts of the HydroCAD analyses are included in the Weaver's Cove East Layover Facility Stormwater Report provided in Appendix 4.17-C. Drainage areas used in the analyses are summarized below and are fully described in Appendix 4.17-C. As noted above, these analyses were not conducted for the Wamsutta Layover Facility.

The closed drainage system for the Weaver's Cove East Layover Facility was designed for the 25-year storm event, in accordance with the MBTA's requirements. Drainage pipes were sized using Manning's Equation for full-flow capacity and the Rational Method. Additionally, the performance of the system was analyzed using StormCAD, a HEC-22 based program. Pipe sizing calculations are included in the Weaver's Cove East Layover Facility Stormwater Report provided in Appendix 4.17-C. These analyses were not conducted for the Wamsutta Layover Facility.

Soil characteristics for the Weaver's Cove East Layover Facility site were assessed according to the USDA NRCS soil mapping. In accordance with the Stormwater Standards, soil infiltration capacity was evaluated according to the 1982 Rawls Rates.

The latest FEMA Flood Insurance Rate Maps (FIRMs) were reviewed for each layover facility site in order to evaluate for potential impacts within the 100 year floodplain. According to the latest maps available from FEMA, neither site was found to be located within the 100 year floodplain. A copy of the latest FIRM for each site is included in the individual layover facility stormwater reports provided in Appendix 4.17-C.

The Secretary's Certificate on the DEIR and the Stormwater Regulations at 310 CMR 10.05(6)(k) require MassDOT to consider ESSD and LID design practices. Within the constraints of the fixed elevation of the existing rail bed and the need to have layover tracks be nearly level, the proposed topography at each layover facility matches the existing topography to the extent practicable and existing drainage patterns would be maintained. To reduce peak runoff rates, existing mature vegetation would be preserved and unnecessary impervious areas would be removed. Runoff from existing and proposed impervious areas is disconnected where possible and directed to LID features such as filter strips, grassed swales, and infiltration basins. Infiltration basins were incorporated wherever possible to mimic natural hydrology and to improve groundwater recharge. Additional LID features such as pervious pavement and rain barrels were evaluated to reduce the amount of connected impervious area at the operations and maintenance buildings.

Non-structural water quantity and quality control BMPs to be implemented at the layover facilities include:

- **Snow Management:** No snow would be placed in, or directly adjacent to wetland resource areas. As much as possible snow would be allowed to melt on pavement where debris and sand may be deposited and swept up for disposal. Snow melt would enter the stormwater management system where it would receive proper treatment.

- **Spill Prevention:** Spill prevention is achieved with the proper storage and handling of hazardous materials. During construction, this is addressed in the SWPPP for Construction Activities that would be prepared prior to the start of construction activities. As required under the Clean Water Act (40 CFR Part 112), an operational phase Spill Prevention, Control and Countermeasures (SPCC) Plan would also be prepared prior to the commencement of operations at each layover facility.

- **Source Control:** A comprehensive source control program would be implemented at each layover facility, which includes regular pavement sweeping, catch basin cleaning, and enclosure and maintenance of all dumpsters, compactors, and loading areas. MBTA would develop a detailed Operations and Maintenance (O&M) Plan during the final design phase of the project and would include it with the Notice of Intent submittal. This plan would address specific maintenance measures that must be performed and the required frequency in order to maintain the stormwater management measures at each layover facility.

Structural water quantity and quality control BMPs to be implemented at each layover facility (not all BMPs are suitable for each site) include:

- **Catch Basins with Sumps and Oil/debris Traps**: Catch basins at layover facilities are to be constructed with sumps (minimum 4 feet) and oil/debris traps to prevent the discharge of sediments and floating contaminants. Catch basins would be inspected and cleaned according to the maintenance schedule laid out in the O&M Plan.

- **Drip Pans (Collection Trays):** As previously described in the DEIS/DEIR, the storage tracks would have drip pans or collection trays to catch any incidental drips, leaks, or spills of hazardous materials that may occur during storage or maintenance of the trains. Runoff and contaminants collected in drip pans would be connected to an oil/grit separator prior to discharge to another BMP or to the municipal storm drain. Drip pans would be inspected and cleaned according to the maintenance schedule laid out in the O&M Plan.

- **Oil/Grit Separator:** MassDEP requires the use of a pretreatment BMP, such as an oil/grit separator, for sites that constitute LUHPPLs. These structures are underground storage tanks consisting of three chambers that are separated by interior baffle walls. The placement of the interior baffles and the outlet from the structure are designed to remove heavy particulates, floating debris and hydrocarbons from stormwater. Oil/grit separators would be cleaned regularly to remove accumulated debris and maintain functionality, in accordance with the maintenance schedule laid out in the O&M Plan.

- **Vegetated (Grass & Gravel) Filter Strip:** A vegetated or grass filter strip is a linear stormwater management measure that is generally oriented parallel to the contributing drainage area and treats sheet flow or small quantities of concentrated flows that can be distributed along the width of the filter strip. A level spreader, consisting of a pea gravel diaphragm or other similar feature, runs the width of the area being treated. The level spread intercepts and dissipates runoff to minimize the risk of erosion due to concentrated flows. Vegetated filter strips are maintained (mowed) in conjunction with standard site landscape maintenance. Periodic inspections of filter strip are necessary to ensure that it is operating as required. Additional guidance for filter strip inspection and maintenance requirements would be provided in the O&M Plan.

- **Vegetated (Grass) Swales:** Vegetated swales provide some treatment, reduction, and distribution of stormwater during conveyance. Pollutant removal mechanisms include filtering by the swale vegetation (both on side slopes and on bottom), filtering through a subsoil matrix,[23] and/or infiltration into the underlying soils. Trash removal and vegetation management are required in conjunction with standard landscape maintenance. Additional guidance for vegetated swale inspection and maintenance requirements would be provided in the O&M Plan.

- **Infiltration Basins:** Infiltration basins are stormwater runoff impoundments that are constructed in areas with permeable soils. Pretreatment of runoff is critical to prevent the basin from becoming clogged with fine sediment and suffering premature failure. Runoff from the design storm is stored until it exfiltrates through the soil of the basin floor. Trash removal and vegetation management are required in conjunction with standard landscape maintenance. Periodic inspections are required to ensure that the basin drains within 72 hours of the design storm event. If the basin is not draining adequately, a layer of sediment may need to be removed from the floor of the basin to restore infiltration capacity. Additional guidance for infiltration basin inspection and maintenance requirements would be provided in the O&M Plan.

[23] The soil matrix is the portion (usually more than 50 percent) of a given soil layer that has the predominant color, http://www.wetlands.com/coe/87manp3b.htm.

Weaver's Cove East Layover Facility

The Weaver's Cove East Layover Facility would be a new overnight layover facility located near the terminus of the Fall River Secondary in Fall River, Massachusetts. The proposed facility would be constructed on an approximately 18 acre site located on the east side of the Fall River Secondary, northeast of the former Weaver's Cove Energy facility. Portions of the site were previously developed, and existing development on the site is limited to approximately 4.4 acres of paved areas, building foundations, and other impervious areas. The site is bounded to the north and south by residential development, to the east by North Main Street, and to the west by the Fall River Secondary and the Taunton River (Figure 4.17-26a). A portion of this layover facility is within the Coastal Zone. Compliance with the Coastal Zone Management Regulations is described in Chapter 4.18, *Coastal Zone Management and Chapter 91*.

Layover Facility Description—The Weaver's Cove East Layover Facility would include six layover tracks, a paved driveway and access aisle around the layover tracks, ancillary landscape improvements, a 41 space parking lot, two operation and maintenance buildings, a power substation and other utility improvements. Constructing this facility would include demolishing concrete pads and multiple bituminous driveways that currently exist on the site and would reduce the impervious area by 0.91 acres. The conceptual design of the Weaver's Cove East Layover Facility is shown on Figure 4.17-26a.

Stormwater Analysis—For the Weaver's Cove East Layover Facility, four design points were identified and the contributing drainage areas to each design point were evaluated under existing and proposed conditions. Peak flow reductions were achieved for all storm events through the use of LID techniques and stormwater BMPs such as reducing impervious area, drip pans, gravel and grass filter strips, oil/grit separators, vegetated swales, sediment forebays, and infiltration basins. The BMPs were sized to manage the water quality volume and recharge volume requirements identified under the Stormwater Standards. The layover facility is within the Taunton River watershed and is subject to the approved TMDL for pathogens in the watershed. It is not anticipated that the layover facility would increase bacteria loads in the watershed.

The proposed drainage areas for Weaver's Cove East Layover Facility are shown on Figure 4.17-26b. Drainage Areas 1, 3, and 4 include vegetated areas as well as smaller amounts of impervious cover from driveways and paved parking areas. Runoff from the impervious portions of these drainage areas would sheet flow over gravel and grass filter strips prior to discharge to vegetated swales that would convey flows to one of the sediment forebays that is associated with Infiltration Basin 2. Overflows from this basin would be discharged via an outlet control structure to the existing closed drainage system which subsequently discharges to the Taunton River.

Three of the drainage areas on the eastern portion of the site (Drainage Areas 2, 6, and 7) would be predominantly landscaped areas with insignificant amounts of impervious cover. Areas of impervious cover within these drainage areas would flow over gravel and grass filter strips for pretreatment. Stormwater runoff from these drainage areas would sheet flow into Infiltration Basins 1, 3, and 4, respectively. These basins are designed to infiltrate all stormwater drainage from their contributing drainage areas that is collected during a 100 year storm event.

Drainage from the western portion of the site that contains the layover tracks, paved access aisles, and paved driveways (Drainage Area 5) would be collected in an underdrain system and directed to an oil/grit separator. Treated flows from the oil/grit separator would then be discharged to a sediment

forebay prior to entering Infiltration Basin 2. Overflows from this basin would be discharged via an outlet control structure to the existing closed drainage system which subsequently discharges to the Taunton River.

Two smaller drainage areas on the western portion of the site (Drainage Areas 8 and 9) consist of pervious areas that sheet flow to an existing ditch and culvert along the railroad right-of-way, prior to discharge to the Taunton River. This drainage pattern would be maintained under the proposed conditions.

Existing and proposed peak discharge rates to each of the design points for the 2, 10, and 100 year storm events are shown in Table 4.17-32.

Table 4.17-32 Peak Discharge Rates (cfs[1])–Weaver's Cove East Layover Facility

Design Point	2-year	10-year	100-year
Design Point 1: Taunton River			
Existing	14.5	23.6	39.0
Proposed	2.7	4.6	22.1
Design Point 2: Wet Area 2			
Existing	4.1	8.4	16.0
Proposed	0.0	0.0	0.0
Design Point 3: Wet Area 3			
Existing	1.5	3.1	5.7
Proposed	0.0	0.0	0.0
Design Point 4: Wetland 4			
Existing	1.5	2.8	5.2
Proposed	0.0	0.0	0.0

1 cubic feet per second

Compliance with Massachusetts Stormwater Standards—Weaver's Cove East Layover Facility has been designed to comply fully with all ten of the Stormwater Standards. Compliance documentation is included in the Weaver's Cove East Layover Facility Stormwater Report (Appendix 4.17-C) and summarized in Table 4.17-33.

Table 4.17-33 Massachusetts Stormwater Standards Compliance – Weaver's Cove East Layover Facility

Standard	Compliance Level Achieved
Standard 1: No New Untreated Discharges or Erosion to Wetlands	Full compliance would be achieved. BMPs are proposed to treat stormwater runoff from the site and outlets and conveyances are protected from erosion.
Standard 2: Peak Rate Attenuation	Full compliance would be achieved. Although this requirement may be waived because the site discharges to land subject to coastal storm flowage as defined in 310 CMR 10.04, peak discharge rates at the design points are expected to be reduced between 1.5 and 19.0 cfs for the range of storm events analyzed.
Standard3: Stormwater Recharge	Full compliance would be achieved. The required recharge volume of 4,785 cubic feet is managed within the infiltration basins. Approximately 118,525 cubic feet of volume is provided in the infiltration basins.
Standard 4: Water Quality	Full compliance would be achieved. Eighty percent TSS removal is achieved for all drainage areas with contributions from impervious surfaces.
Standard 5: Land Uses with Higher Potential Pollutant Loads	Full compliance would be achieved. The layover facility qualifies as a LUHPPL because the use is regulated under the NPDES Multi-Sector General Permit. Containment and treatment measures would be used to prevent the release of oil or hazardous materials.
Standard 6: Critical Areas	Full compliance would be achieved. The site does not discharge near or to a critical area.
Standard 7: Redevelopment Standards	Full compliance would be achieved. Although a portion of this site constitutes redevelopment, it would fully comply with all ten Stormwater Standards.
Standard 8: Construction Period Pollution Prevention and Erosion and Sedimentation Controls	Full compliance would be achieved. The project would obtain coverage under the NPDES Construction General Permit prior to the start of earthmoving activities.
Standard 9: Operation and Maintenance Plan	Full compliance would be achieved. MassDOT would develop a detailed O&M plan during final design as part of the Notice of Intent submittal.
Standard 10: Prohibition of Illicit Discharges	Full compliance would be achieved. Storm drainage structures remaining from the previous development which are part of the redevelopment area would be removed. The proposed layover facility has been designed so that the components included therein are in full compliance with current standards. No statement is made with regard to the drainage system in portions of the site not included in the redevelopment project area.

Wamsutta Layover Facility

The Wamsutta Layover Facility would be a new overnight layover facility near the terminus of the New Bedford Main Line in New Bedford, Massachusetts. The site of the proposed facility is an approximately 9 acre parcel that was historically used as a railroad yard. A three-foot thick, permeable, engineered

barrier was constructed on top of the historic railroad yard. The infrastructure for the proposed layover facility is designed to minimize disturbance to the engineered barrier and would be constructed with as few protrusions into the barrier as possible. The facility would be located between the existing freight tracks to the east, a row of commercial properties on Wamsutta Street to the north, Whale's Tooth Station to the south, and the New Bedford Main Line to the west (Figure 4.17-27). Construction of the layover facility would increase the impervious area by approximately 2.0 acres. A portion of this layover facility is within the Coastal Zone. Compliance with the Coastal Zone Management Regulations is described in Chapter 4.18, *Coastal Zone Management and Chapter 91*.

Layover Facility Description—The Wamsutta Layover Facility would include six layover tracks, a paved driveway and access aisle around the layover tracks, ancillary landscape improvements, a 39 space parking lot, two operations and maintenance buildings, a power substation and other utility improvements. The conceptual design of the Wamsutta Layover Facility is shown on Figure 4.17-27.

Stormwater Analysis—For the Wamsutta Layover Facility, three design points were identified and the contributing drainage areas to each design point were evaluated under existing and proposed conditions. LID techniques and stormwater BMPs such as drip pans, oil/grit separators, water quality manholes, and vegetated swales would be used to manage and treat runoff. The BMPs were sized to manage the water quality volume requirements identified under the Stormwater Standards. Because the layover facility is located on a site where contamination is capped in place, recharge is required only to the maximum extent practicable. The site drains to the municipal separate storm sewer within a coastal watershed and is not required to manage runoff for peak rate controls. The layover facility is within the Buzzards Bay watershed and is subject to the approved TMDL for pathogens in the watershed. It is not anticipated that the proposed layover facility would increase bacteria loads in the watershed.

At this time, no ground survey is available for the site. As a result, the proposed drainage design is conceptual and hydrologic, hydraulic, and geotechnical analyses have not been completed. It is important to note that the cap under the proposed Wamsutta Layover was designed and built with consideration for a future layover; it is staged, therefore, to accommodate the SCR facility. The Wamsutta Layover was also designed to not impact the cap. If, however, there is impact it would be mitigated to maintain the cap's functionality.

Compliance with Massachusetts Stormwater Standards—The Wamsutta Layover Facility would be designed to comply fully with all ten of the Stormwater Standards. Preliminary compliance documentation is included in the Wamsutta Layover Facility Stormwater Report (Appendix 4.17-C) and summarized in Table 4.17-34.

Table 4.17-34 Massachusetts Stormwater Standards Compliance–Wamsutta Layover Facility

Standard	Compliance Level Achieved
Standard 1: No New Untreated Discharges or Erosion to Wetlands	Full compliance would be achieved. The site would continue to drain to existing municipal storm sewers.
Standard 2: Peak Rate Attenuation	Full compliance would be achieved. This requirement may be waived because the site discharges to land subject to coastal storm flowage as defined in 310 CMR 10.04.
Standard3: Stormwater Recharge	Full compliance would be achieved. Because the site is located on a site where contamination is capped in place, MassDEP requires infiltration only to the maximum extent practicable.
Standard 4: Water Quality	Full compliance would be achieved. Eighty percent TSS removal would be achieved for all drainage areas with contributions from impervious surfaces.
Standard 5: Land Uses with Higher Potential Pollutant Loads	Full compliance would be achieved. The layover facility qualifies as a LUHPPL because the use is regulated under the NPDES Multi-Sector General Permit. Containment and treatment measures would be used to prevent the release of oil or hazardous materials.
Standard 6: Critical Areas	Full compliance would be achieved. The site does not discharge near or to a critical area.
Standard 7: Redevelopment Standards	Full compliance would be achieved. Although this site constitutes redevelopment, it would fully comply with all ten Stormwater Standards.
Standard 8: Construction Period Pollution Prevention and Erosion and Sedimentation Controls	Full compliance would be achieved. The project would obtain coverage under the NPDES Construction General Permit prior to the start of earthmoving activities.
Standard 9: Operation and Maintenance Plan	Full compliance would be achieved. MassDOT would develop a detailed O&M plan during final design as part of the Notice of Intent submittal.
Standard 10: Prohibition of Illicit Discharges	Full compliance would be achieved. With the exception of storm drainage infrastructure that is associated with the engineered barrier at the site, storm drainage structures remaining from the previous development which are part of the redevelopment area would be removed. The proposed layover facility has been designed so that the components included therein are in full compliance with current standards. No statement is made with regard to the drainage system in portions of the site not included in the redevelopment project area.

Layover Summary

The two layover facilities that would be constructed would fully comply with the Stormwater Standards. Table 4.17-35 provides summarizes key stormwater information related to the proposed layover facilities. Both layover facilities are considered "redevelopment" since they have been partially or fully sited on previously developed land. The layover facilities have been designed with appropriate BMPs to manage and treat stormwater runoff from a LUHPPL. Both facilities are proposed within coastal watersheds, and are not required to manage runoff for peak rate controls.

Table 4.17-35 Layover Facility Summary

Layover Facility	Existing or Proposed Facility	Meets Redevelopment Criteria	Discharge Location or Receiving Waterbody	Within TMDL Watershed	Change in Impervious Area (ac)
Weaver's Cove East	Proposed	Yes	Taunton River	Yes[1]	+0.9
Wamsutta	Proposed	Yes	MS4	Yes[2]	+2.0

1 MassDEP, 2011. *Final Pathogen TMDL for the Taunton River Watershed*. June 2011. Control Number: CN 256.0.
2 MassDEP, 2009. *Final Pathogen TMDL for the Buzzards Bay Watershed.* March 2009. Control Number: CN 251.1.

4.17.3.4 Temporary Construction-Period Impacts

In the absence of mitigation, the construction phases for each Build Alternative could result in short-term, temporary impacts that would end when construction is complete. As construction would take several years, these impacts would vary in time and place as different phases of the project were completed. A NPDES permit, specifically, the General Permit for Discharges From Construction Activities[24] (effective February 16, 2012) would be required from the U.S. Environmental Protection Agency, and would specify measures required to prevent construction-related stormwater impacts.

Although the Build Alternatives differ, the types of construction-related impacts would be similar. Water quality impacts, reduction to groundwater recharge, and changes to surface hydrology due to construction could be caused by three primary types of activities:

- Erosion and sedimentation from earthwork;
- Spills of hazardous materials; and
- Dewatering.

The construction of rail lines, highways, bridges, culverts, stations, and layover facilities would expose unvegetated soil that could erode and be deposited in local waterways if appropriate mitigation measures were not taken. This increased sediment load could have an adverse effect on organisms in the receiving waters by increasing the turbidity of the water, altering the channel shape, covering eggs or other sensitive life stages with silt, or transporting any contaminants associated with the sediments. The construction of bridges or culverts may involve construction within a stream or other waterbody using cofferdams, which could disturb sediments in the streambed or lakebed and have similar effects. Cofferdams would temporarily alter flow in the stream channel and could cause increased sedimentation upstream until the cofferdams were removed. Excavation and construction near known contaminated sites would be more likely to encounter contaminated sediments than construction in clean or undisturbed areas.

Construction using heavy equipment would require storing and transporting fuel on site. An accidental release of fuel during refueling could have the potential to contaminate soil, groundwater, and surface water. Potential impacts would be more pronounced in proximity to drinking water supplies, such as within Zone I, Zone II, or Zone A areas. Spill containment procedures, including limiting the areas in which fueling could be performed, would be implemented to minimize any risk of spills or

[24] US Environmental Protection Agency. 2012. National Pollutant Discharge Elimination System General Permit for Discharges from Construction Activities. US EPA, April 16, 2013, <http://www.epa.gov/npdes/pubs/cgp2012_finalpermit.pdf> (April 25, 2013)

contamination. With proper containment and handling procedures in place, there would be no effects on surface or groundwater resources after construction was completed.

Construction near or within streams and wetland areas may require dewatering during construction activities to keep excavated areas free of groundwater. Untreated dewatering fluids are typically filled with silt and sediment, which could be harmful to surface waters if discharged directly. Dewatering could also expose pollutants from contaminated groundwater, particularly near existing contaminated sites. Any contamination encountered would be handled appropriately in compliance with Massachusetts standards and in coordination with MassDEP. All dewatering discharges would require controls as described in Section 4.17.3.6, *Mitigation*.

Based on this assessment, the potential impacts to surface and groundwater resources during construction could be prevented with proper construction management and monitoring. With mitigation in place, none of the potential construction-period impacts would have any significant or long-term effects on surface and groundwater resources. Section 4.17.3.6, *Mitigation*, describes proposed mitigation measures for short- and long-term impacts to surface and groundwater resources.

4.17.3.5 Summary of Impacts By Alternative

This section summarizes the potential direct and indirect effects on water resources from each of the South Coast Rail alternatives (Table 4.17-36). All of the Build Alternatives would have the potential to affect waterbodies and drinking water protection areas. All of the Build Alternatives would require construction within public water supply Zone I areas, which is the area within 400 feet of a well that is generally afforded the greatest protection from development. All of the Build Alternatives would upgrade existing transit corridors, which would have a negligible effect on pollutant loading. The Build Alternatives would upgrade existing transit corridors but would also build new rail lines on disused rail corridors, potentially introducing new pollutant sources in those areas. With mitigation and drainage features in place, none of the Build Alternatives are expected to impair any water resources.

Table 4.17-36 Summary of Potential Water Resource Impacts by Alternative

	Proposed Stormwater Discharges to Waterbodies		Construction in Drinking Water Protection Areas[1]				Proposed Stormwater Discharges to Drinking Water Protection Areas[1]			
Alternative	ACEC/ ORWs	Non-ORWs	Zone A	Zone I	Zone II	IWPA	Zone A	Zone I	Zone II	IWPA
Stoughton Electric	2	9	1	0	6	2	1	0	6	2
Stoughton Diesel	2	9	1	0	6	2	1	0	6	2
Whittenton Electric	2	10	1	1	10	2	1	0	10	2
Whittenton Diesel	2	10	1	1	10	2	1	0	10	2

Potential impacts to the Hockomock Swamp and Fowl Meadow ACEC would occur due to stormwater discharges to Black Brook and the East Branch of the Neponset River, respectively from the Stoughton and Whittenton Alternatives. However, minimal impacts to ACECs from stormwater discharges would occur from the project. None of the above-mentioned discharges are associated with constructed

stations, station platforms or parking areas. These discharges would primarily occur from conveyed overland flow from ditches along the railroad, which would carry negligible contaminant loads. None of the proposed actions are expected to impair surface or groundwater resources within the ACEC. Compliance with the Massachusetts Stormwater Management Standards is provided for all stations except Stoughton and Dana Street. Compliance would be documented for these stations (as necessary) during later project design phase phases.

Stoughton Electric Alternative

The Stoughton Electric Alternative would involve construction within one Zone A area, Zone II areas for six wells, and the IWPA for two wells. These areas would be disturbed only temporarily and would not receive any long-term impacts. This alternative would also require stormwater discharges to one Zone A area, Zone II areas for six wells, the IWPA for two wells, and 10 different waterbodies, including one ORW within the Hockomock Swamp ACEC and the East Branch of the Neponset River in the Fowl Meadow ACEC.

One new station, Easton Village Station, would be located in a Zone II area but would not have any impact on groundwater quality. With stormwater management measures in place, none of the stations or layover facilities is expected to impair any surface or groundwater resources.

While much of the rail corridor for this alternative already conveys diesel rail traffic under existing conditions, reconstructing the Stoughton Line south of Stoughton Station would reintroduce rail traffic to a historic rail corridor. However, the Stoughton Electric Alternative is not expected to contribute contaminants that would impair surface or groundwater resources. The proposed drainage design includes measures to control new potential pollutant sources and would meet Massachusetts Stormwater Management Standards. Specifically, the proposed conceptual drainage design would ensure that treatment trains are used at station sites that provide 80 percent Total Suspended Solids (TSS) removal and at least 44 percent TSS removal for discharges to Zones I, II and IWPA areas, as required by the Standards. Appropriate setbacks, volume controls and pretreatment requirements for these Zones and ORW's would be met. Consultation with DEP, the North Raynham Water District, and Easton Water Division during design would be undertaken during the design process. With mitigation and drainage features in place, the Stoughton Electric Alternative is not expected to impair any surface or groundwater resources.

Stoughton Diesel Alternative

The Stoughton Diesel Alternative would be comprised of the same elements as the Stoughton Electric Alternative as listed above and would have the potential to affect the same water resources. The Stoughton Diesel Alternative would have a slightly greater potential for pollutant loading due to the use of diesel fuel. Much of the rail corridor for this alternative already conveys diesel rail traffic under existing conditions; however, reconstruction of the Stoughton Line south of Stoughton Station would reintroduce rail traffic to a historic rail corridor. With mitigation and drainage features in place, the Stoughton Diesel Alternative is not expected to contribute contaminants that would impair surface or groundwater resources.

Whittenton Electric Alternative

The Whittenton Electric Alternative would involve construction within one Zone A area, the Zone I area for one well, Zone II areas for 10 wells, and the IWPA for two wells. These areas would be disturbed only temporarily and would not receive any long-term impacts. This alternative would also require

stormwater discharges to the Hockomock Swamp ACEC and the East Branch of the Neponset River in the Fowl Meadow ACEC.

However, this alternative would require stormwater discharges to one Zone A area, Zone II areas for 10 wells, the IWPA for two wells, and 11 different waterbodies. One new station, Easton Village Station, would be located in a Zone II area but would not have any impact on groundwater quality. With stormwater management measures in place, none of the stations or layover facilities is expected to impair any surface or groundwater resources.

While much of the rail corridor for this alternative already conveys diesel rail traffic under existing conditions, using the Whittenton Branch and reconstructing the Stoughton Line south of Stoughton Station would reintroduce rail traffic to a historic rail corridor. However, the Whittenton Electric Alternative is not expected to contribute contaminants that would impair surface or groundwater resources. The proposed drainage design includes measures to control new potential pollutant sources and would meet Massachusetts Stormwater Management Standards. With mitigation and drainage features in place, the Whittenton Electric Alternative is not expected to impair any surface or groundwater resources.

Whittenton Diesel Alternative

The Whittenton Diesel Alternative would be comprised of the same elements as the Whittenton Electric Alternative as listed above and would have the potential to affect the same water resources. The Whittenton Diesel Alternative would have a slightly greater potential for pollutant loading due to the use of diesel fuel. Much of the rail corridor for this alternative already conveys diesel rail traffic under existing conditions; however, using the Whittenton Branch and reconstruction of the Stoughton Line south of Stoughton Station would reintroduce rail traffic to disused rail corridors. With mitigation and drainage features in place, the Whittenton Diesel Alternative is not expected to contribute contaminants that would impair surface or groundwater resources.

4.17.3.6 Mitigation

This section summarizes the avoidance, minimization, and mitigation measures proposed to protect and maintain water resources under each of the alternatives assessed in this report.

Avoidance

This section discusses steps taken to avoid impacts to water resources under each alternative. The Build Alternatives are discussed together due to their similar design methodology and construction requirements.

No-Build (Enhanced Bus) Alternative

The No-Build Alternative does not involve any construction or potential water resource impacts. The alternative uses existing bus routes and park-and-ride locations and has negligible potential for impacts to surface and groundwater resources.

Build Alternatives

The transit corridors selected for each Build Alternative were based on existing and former transit corridors such as the New Bedford Main Line and the Stoughton Line. Total avoidance of water

resources was not possible because these corridors have already been established and cross various surface and groundwater resources.

Stations and Layover Facilities

Where possible, new or reconstructed stations and new layover facilities were located away from waterbodies and drinking water protection areas. None of the stations or layover facilities are located in Zone I or Zone A areas, which require the greatest degree of protection from development in order to protect drinking water quality. However, the site selection for these facilities focused on locations that would enhance ridership and meet the operational requirements of the South Coast Rail alternatives.[25] Therefore, total avoidance of groundwater resources was not possible.

Minimization

Proposed station and parking facilities for all alternatives were located on developed sites whenever possible to minimize any increases in impervious area and to avoid introducing new pollutant sources to undeveloped areas. Additional minimization measures to reduce impervious surfaces such as deck parking, the use of water quality swales, narrower streets and green "islands”, a reduced building footprint, and alternative (permeable) materials for parking areas, sidewalks and roads at stations would be considered during the design stage of the project. Further minimization along the proposed transit corridors was not possible, as the corridors themselves were determined by existing and former highway and rail alignments and could not be relocated without substantial increases in impacts to other resources.

Specific Mitigation Measures

This section discusses mitigation measures required to protect water resources under each of the Build Alternatives. Most of these measures are common to multiple alternatives. Only a few select mitigation measures are presented due to the steps taken to minimize potential impacts such as the avoidance of stormwater discharges to sensitive resource areas (Zone I) and the minimization of discharges throughout the alternative project areas. All stormwater BMPs would meet or exceed regulatory requirements to suggest mitigation for potential impacts. These BMPs would be further refined during the design stage of the project.

Common to All Build Alternatives — Construction

Construction of the Build Alternatives would require a General Permit for Discharges From Construction Activities (effective February 16, 2012) would be required from the U.S. Environmental Protection Agency, pursuant to the National Pollutant Discharge Elimination System (NPDES). A comprehensive Stormwater Pollution Prevention Plan (SWPPP) would be a condition of the General Permit. The SWPPP would describe potential pollutant sources on a site and dictate what best management practices (BMPs) must be implemented to manage stormwater and protect water quality. Any soil-disturbing activities would require erosion and sediment controls, including proper timing of construction to minimize the time that an area is left exposed, temporary stabilization of exposed areas using protective covers, and perimeter controls to capture sediment before it leaves the site. Erosion and sedimentation controls are for use during the earthwork and construction phases of the project and may include

[25] Executive Office of Transportation and Public Works, South Coast Rail Station Siting Report: EOT’s Final Recommendations, October 10, 2008.

structural management practices such as hay bale barriers, silt fencing, compost mulch socks, catch basin inlet protection, gravel construction entrances, diversion channels, and temporary sedimentation basins. Non-structural management practices may include vegetative slope stabilization and construction sequencing. Daily monitoring would be performed to ensure that the controls are effective. Large areas of disturbance (such as at new station sites) could require temporary sedimentation basins.

Spill control procedures would be in place at designated fueling locations and temporary sanitary facilities to control any accidental spills of fuel or other hazardous materials. These locations would be isolated from surface waters and provided with spill-recovery equipment. Waste materials would be disposed of properly and not left in the open where they could contaminate soil or runoff.

Any dewatering activities for excavation, channel relocation, or fill would require proper handling of the dewatering discharge. To minimize dewatering discharges, the pump intake would be kept above the bottom of the excavation. Any contaminated dewatering discharge would be stored and disposed of in accordance with Massachusetts waste disposal standards in coordination with MassDEP. Uncontaminated water would be discharged to a vegetated land surface or pumped into an upland settling basin (or confined disposal facility) surrounded by hay bales or silt fences. Overflow water from the settling basin would be discharged into nearby waters of the United States in accordance with provisions of the Corps Section 404 permit, and the basin and all accumulated sediment would be removed following dewatering operations and the area would be seeded and mulched.

Common to All Build Alternatives—Stations

All proposed station sites would be designed to meet the Massachusetts Stormwater Management Standards (310 CMR 10.05(6)) and the proposed Massachusetts Stormwater Management Regulations (314 CMR 21.00). Together, these regulations require peak flow management as well as stormwater treatment such as removal of suspended solids.

Five stations require mitigation measures in order to comply with the Stormwater Standards. The BMPs incorporated into the design for these stations are summarized in Table 4.17-37, and include such LID and ESSD measures as vegetated swales, filter strips, bioretention swales, bioretention basins, and infiltration basins as well as structural BMPs such as oil/grit separators.

Table 4.17-37 Station Site Stormwater BMP Matrix

Station Name	Oil/Grit Separator	Vegetated Swale	Gravel & Grass Filter Strip	Bioretention Swale	Bioretention Basin	Infiltration Basin
North Easton Station	X	X			X	X
Raynham Park Station		X	X	X	X	
Taunton Station		X			X	
Taunton Depot Station		X			X	
Freetown Station		X				X
Fall River Depot Station	X					

Common to all Build Alternatives—Layover Facilities

The layover facilities would be regarded as Land Uses with Higher Potential Pollutant Loads (LUHPPLs) under the Stormwater Management Standards and would be held to a higher standard of treatment than the other elements of the project. The two overnight layover facilities have been designed with the appropriate BMPs to comply with the Stormwater Standards. The mitigation measures proposed for these facilities are summarized in Table 4.17-38, and include drip pans, oil/grit separators, vegetated swales, filter strips, and infiltration basins. A water quality manhole is proposed at the Wamsutta Layover Facility due to the unique constraints posed by this capped property.

Table 4.17-38 Layover Facility Stormwater BMP Matrix

Layover Facility Name	Drip Pan	Oil/Grit Separator	Vegetated Swale	Gravel & Grass Filter Strip	Water Quality Manhole	Infiltration Basin
Weaver's Cove East	X	X	X	X		X
Wamsutta	X	X	X		X	

Typical LID and infiltration-based stormwater management techniques may not be appropriate for the layover facilities due to their LUHPPL status, although open drainage systems may be possible for the access roads into the facilities. Closed or partially-closed drainage systems would be used to manage stormwater runoff within the site. The stormwater drainage would be designed to control runoff rates and maintain groundwater recharge. The only major potential pollutant source within the facilities would be locomotives in storage, which may drip small amounts of oil or other hazardous materials while in the facility. In addition to standard total suspended solids (TSS) removal BMPs for paved areas, the site would include specific drainage features to contain hazardous materials that may be encountered on the storage tracks. Drip trays and oil/water separators would be included in the layover facilities to capture and divert any pollutants that may collect under the locomotives. With these measures in place, the layover facilities are expected to satisfy the LUHPPL treatment requirement and meet the Stormwater Management Standards.

Build Alternatives

There are several mitigation measures that would be used along the rail lines and at the stations to prevent contamination of stormwater, groundwater, and waterbodies:

- The rail corridor would be supported by pervious ballast (or a trestle structure in some areas), which would have a minimal effect on stormwater drainage. Existing drainage ditches along the rail corridors would be improved, expanded, or relocated as needed to ensure proper drainage during storms. In accordance with the requirements of the Secretary's Certificate, drainage improvements would include specific measures to protect critical areas adjacent to the rail corridor. Detailed drainage plans for the entire project area would be completed in conjunction with final grading design. Locations where specific BMPs are recommended or required are identified below.

- Vegetated swales are proposed for use where the rail bed is in a cut or on a wide embankment with sufficient room to construct swales.

- Sediment forebays with checks dam are proposed for use at the downstream end of vegetated swales where flows are routed to a pipe for further conveyance, and at the downstream end of vegetated swales where flows are discharged to a wetland or other surface water.

- Underdrains with cleanouts are proposed for use where the right-of-way is too narrow to construct vegetated swales. In locations where underdrains are proposed in the vicinity of vernal pools, the elevation of seasonal high groundwater should be evaluated to ensure that underdrains do not inadvertently cause the vernal pool to drain prematurely.

- Stone-lined swales with HDPE liners are required for use near public water supply well Zone 1 areas, such as near the Easton GP Well #1 on Gary Lane in Easton. Lined swales are also required for use where drainage swales may intercept seasonally high groundwater in the vicinity of vernal pools. Interception of groundwater in these areas may cause pools to drain prematurely.

- Outlet scour protection is proposed for use where concentrated flow is discharged, typically pipe outlets with flared end sections or headwalls.

- Infiltration trenches are proposed for use to manage stormwater runoff associated with the Hockomock Swamp Trestle. Infiltration trenches would be constructed beneath the trestle at intervals to manage runoff from the overlying sections of trestle.

- The potential for creosote contamination from the rail ties can be reduced or eliminated by using alternative rail tie materials such as concrete wherever possible to avoid the need for creosote treatment. The South Coast Rail project has specified concrete ties as a standard element for new tracks. Wooden ties may be preferred at some turnouts, switches, special track work, and anywhere noise is a primary concern, as wooden ties usually result in quieter train operations than concrete ties.

- Rail greasers would be required at numerous curves in the track. Filter fabric would be placed atop the ballast at greaser locations to capture excess grease. This fabric would be replaced periodically in order to prevent excessive grease accumulation that could lead to stormwater or groundwater contamination.

- Herbicide would be used to keep the rail corridor free of intrusive and obstructive vegetation in order to ensure the stability of the railbed and the safety of trains. To minimize the potential for water quality impacts from herbicide use, an approved Vegetation Management Plan, as implemented with its Yearly Operating Plans would be adhered to which restrict the use of herbicides in areas adjacent to wetlands or sensitive resources.

- Traction power substations would be required along the rail line for the electrically-powered alternatives. To prevent potential water contamination from the oil in the transformers, these substations would be designed with secondary containment structures that would surround the equipment and contain any leaks or spills until the hazardous material could be collected.

- The sanitary tanks on the trains would be unloaded at the mid-day layover facility. The sanitary waste from the trains would not pose a risk to water resources under normal operations.

- Culverts would be evaluated for potential modification and upgrades to meet stream crossing standards and enhance wildlife, to the maximum extent practicable. All crossings would be evaluated. Where feasible, culverts would be replaced in-kind at stream crossings to prevent hydrologic changes to local streams, improve and restore fish and wildlife passing, decrease fragmentation of genetic pools, and improve connectivity between environmental resources. Design would be developed in consultation with DEP and the Corps and according to the Massachusetts River and Stream Crossing Standards.

Summary of Mitigation

All Build Alternatives would require stormwater management measures to prevent flooding and protect water quality. With the proposed mitigation measures in place, none of the Build Alternatives would be expected to substantially increase pollutant loading or impair any surface or groundwater resources.

4.17.3.7 Regulatory Compliance

Surface and groundwater resources are protected under several federal and state regulatory programs. This chapter documents how the proposed project complies with each water regulatory program.

Federal Regulations

Federal regulations related to stormwater and water quality include Sections 303(d), 311, and 402 of the Clean Water Act (33 U.S.C. 1251 et seq.) and the Safe Drinking Water Act (42 U.S.C. 300f et seq.).

Clean Water Act Section 303(d)

Section 303(d) of the Clean Water Act requires states, territories, and authorized tribes develop lists of impaired waters. These impaired waters do not meet the water quality standards that have been set for them, even after the minimum required levels of pollution control technology have been installed at point sources of pollution. The law requires that the jurisdiction establish priority rankings for waters on the lists and develop TMDLs for them. TMDLs identify the major contributors to a given impairment (e.g., sources within a watershed that may contribute to the contamination or impairment) and specifies both general and individual discharge limits that must be met in order to reduce contaminant loading and improve the health of the waterbody. If a project impacts a waterbody listed under the TMDL program, appropriate measures must be taken to control the discharge of the listed pollutant and meet the TMDL requirements. Some TMDLs may require additional measures (including stormwater treatment) in order to prevent an increase in pollutant loading to the receiving water.

Elements of the project are located within three watersheds with approved TMDLs; these watersheds are the Neponset River, Taunton River, and Buzzards Bay.[26,27,28] All of the project elements would be constructed to prevent the release of sanitary sewage into receiving waters, which is the major source

[26] MassDEP. 2009. *Final Pathogen TMDL for the Buzzards Bay Watershed* March 2009 (Control Number: CN 0251.1).
[27] MassDEP. 2011. *Final Pathogen TMDL for the Taunton River Watershed* June 2011 (Control Number: CN 0256.0).
[28] MassDEP. 2002. *Final Total Maximum Daily Loads of Bacteria for Neponset River Basin*. DEP, DWM TMDL Report MA73-01-2002. Control Number: CN 0121.0. May 31, 2002.

of bacteria or other pathogens that are the cause of the impairment under these TMDLs. As noted in the TMDL for the Taunton River watershed, "The expectation for WLAs [waste load allocations] and LAs [load allocations] for stormwater discharges is that they will be achieved through the implementation of BMPs and other controls." Filtration and infiltration practices are proposed at station sites and layover facilities with new impervious area. These BMPs would help to minimize bacteria loading from ambient sources such as birds and other wildlife. The project would not add any new sources of bacteria or other pathogens within the TMDL watersheds.

Clean Water Act Section 311

Section 311 of the Clean Water Act (40 CFR 112) regulates the prevention and response to accidental releases of oil and hazardous substances into navigable waters, on adjoining shorelines, or affecting natural resources belonging to or managed by the United States. As required under Section 311, an operational phase SPCC would be prepared prior to the commencement of operations at each layover facility.

Clean Water Act Section 402

Section 402 of the Clean Water Act regulates the discharge of pollutants to surface waters. Under the National Pollutant Discharge Elimination System (NPDES) program that is authorized by this section of the Clean Water Act, owners and operators of point source discharges and certain non-point discharges (such as stormwater runoff) are required to obtain a permit prior to discharging.

The South Coast Rail project would require authorization to discharge stormwater during construction under the NPDES General Permit for Construction Activities, administered in Massachusetts by the U.S. Environmental Protection Agency, and which regulates erosion control, pollution prevention, and stormwater management at construction sites over 1 acre. This permit would require a SWPPP that would specify proper stormwater management procedures for any disturbed areas. Construction period impacts to water quality would be reduced or eliminated through the use of appropriate BMPs. These BMPs would be documented in the SWPPP and would include perimeter sedimentation controls (silt fence, hay bales, filter berms, siltation booms), temporary stabilization of disturbed areas, and temporary siltation basins where appropriate. The SWPPP would be completed during the final design phase and must be implemented by the project contractor. Authorization to discharge stormwater under the General Permit for Construction Activities would be requested via a Notice of Intent prior to the commencement of construction.

In addition, the layover facilities would also require permission to discharge stormwater during operation. The NPDES Multi-Sector General Permit for Industrial Activities describes stormwater effluent limits, monitoring requirements and other conditions related to post-construction operations at the facilities. A site-specific SWPPP would be completed for each facility that provides an assessment of potential sources of pollutants in stormwater runoff and control measures that would be implemented at the layover facility to minimize the discharge of these pollutants in runoff from the site. These control measures include site-specific BMPs, maintenance plans, inspections, employee training, and reporting. Authorization to discharge stormwater under the Multi-Sector General Permit would be requested via a Notice of Intent prior to the commencement of operations at each facility.

Safe Drinking Water Act

The Safe Drinking Water Act authorizes the USEPA to set national health-based standards for drinking water to protect against both naturally occurring and man-made contaminants that may be found in drinking water. The South Coast Rail project would not impact public drinking water supplies and includes measures to prevent the release of contaminants in the vicinity of public water supplies.

State Regulations

The state applies regulatory measures pursuant to its authority under the Massachusetts Clean Waters Act (MGL Chapter 21, §26 53) and the Massachusetts Wetlands Protection Act (MGL Chapter 21, §26 53). Regulations promulgated under the Clean Waters Act include the Surface Water Quality Standards (314 CMR 4.00), Groundwater Quality Standards (314 CMR 6.00), and Section 401 Discharge regulations (314 CMR 9.00). Authority to regulate stormwater discharges is incorporated into the Massachusetts Wetlands Protection Act Regulations (310 CMR 10.05) as the Massachusetts Stormwater Standards [310 CMR 10.05(6)(k)].

Massachusetts Surface Water Quality Standards (314 CMR 4.00).

The Massachusetts Surface Water Quality Standards (314 CMR 4.00) assign class designations to inland and coastal waters. These classes specify water quality standards based on the intended uses of the waterbodies and prohibit degradation of these waterbodies by new discharges. The South Coast Rail project does not include any new discharges that would impair the ability of a waterbody to meet its designated use. Comments on the DEIS/DEIR asked MassDOT to confirm the classifications for the waterbodies potentially affected by the project and to update the listing of impaired waters with the most recent Integrated List of Waters. Based on information published by MADEP on their website, none of the waterbody classifications were found to have changed since the DEIS/DEIR.

In addition to the water classifications in 314 CMR 4.00, MADEP also maintains the Massachusetts Integrated List of Waters, which is updated every 2 years and provides more detail on individual waterbodies. This list identifies what designated uses are attained, what impairments have been reported, and whether or not a TMDL has been prepared, if required. The TMDL program is part of Section 303(d) of the Clean Water Act and is also described above under Federal Regulations. Comments on the DEIS/DEIR asked MassDOT to update the listing of impaired waters with the most recent Integrated List of Waters. MADEP most recently published the Integrated List of Waters in 2010.[29] Only minor changes to waterbodies potentially affected by the project were noted when comparing the 2006 list to the 2010 list. These changes included an assessment of Forge Pond in Canton that indicated that the pond is impaired for turbidity (the pond was previously unassessed) and the approval of TMDLs for the Buzzards Bay and Taunton River Watersheds. As previously noted, these approved TMDLs address pathogens in discharges within the watershed.

Massachusetts Groundwater Quality Standards (314 CMR 6.00)

Compliance with the Stormwater Standards ensures that the project would not affect groundwater discharge that supports base stream flows, as well as protecting water quality. The South Coast Rail

[29] MassDEP. 2010. Massachusetts Year 2010 Integrated List of Waters, Final Listing of the Condition of Massachusetts' Waters Pursuant to Sections 305(b), 314 and 303(d) of the Clean Water Act, Featuring new water quality assessments for the Chicopee, French, Quinebaug and Nashua watersheds and the Narragansett Bay and Mount Hope Bay Coastal Drainage Areas.

project includes BMPs designed to promote recharge of groundwater to the maximum extent practicable. Pretreatment of runoff prior to recharge would ensure that groundwater quality is not impacted by the project.

Massachusetts Section 401 Discharge Regulations (314 CMR 9.00)

Section 401 of the Clean Water Act (33 U.S.C. 1341) requires any applicant for a federal license or permit to conduct any activity that may result in a discharge of a pollutant into waters of the United States to obtain a certification from the State in which the discharge originates or would originate, that the discharge would comply with the applicable effluent limitations and water quality standards. Under these regulations, the MassDEP is required to issue Water Quality Certifications for projects that result in discharge of fill to a wetland or waterbody, pursuant to the Massachusetts Clean Waters Act (MGL Ch. 21 § 26-53). The South Coast Rail project would require issuance of an individual Water Quality Certification as it would result in the loss of more than 5,000 square feet of wetlands subject to federal jurisdiction.

Massachusetts Stormwater Standards (310 CMR 10.05)

The Stormwater Standards consist of ten stormwater performance standards that were developed by the MassDEP to reduce the impacts of development on water quality. This section lists each of the Stormwater Standards and identifies how the South Coast Rail project would comply with each one. Supporting calculations documenting compliance with each standard are presented in Appendix 4.17-B (Stations), Appendix 4.17-C (Layover Facilities), and Appendix 4.17-A (Hockomock Swamp Trestle).

1. No new stormwater conveyances may discharge untreated stormwater directly to or cause erosion in wetlands or waters of the Commonwealth.

- The South Coast Rail project has been designed to fully comply with Standard 1.
- BMPs proposed upgradient from any new discharge have been designed in accordance with the Massachusetts Stormwater Handbook and provide the required treatment volume.
- All proposed stormwater outlets and conveyances have been designed to not cause erosion or scour to wetlands or receiving waters. Outlets from closed drainage systems have been designed with flared end sections or headwalls with stone protection to dissipate discharge velocities. Overflows from BMPs that impound stormwater have been designed with stone to protect down gradient areas from erosion during large storm events.

2. Stormwater management systems shall be designed so that post-development peak discharge rates do not exceed pre-development peak discharge rates. This Standard may be waived for discharges to land subject to coastal storm flowage as defined in 310 CMR 10.04.

- The South Coast Rail project has been designed to fully comply with Standard 2.
- For each station site, layover facility, and structure with new impervious area, the rainfall-runoff response was analyzed under existing and proposed conditions for storm events with recurrence intervals of 2, 10, and 100 years. Stormwater BMPs with volume storage are proposed at each location where post-development peak discharges would require attenuation. In accordance with Standard 2, sites with discharges to coastal waters (Fall

River Depot Station, Battleship Cove Station, Whale's Tooth Station, Weaver's Cove East Layover Facility, and Wamsutta Layover Facility) may waive this standard and are not required to incorporate attenuation structures.

3. Loss of annual recharge to groundwater shall be eliminated or minimized through the use of infiltration measures including environmentally sensitive site design, low impact development techniques, stormwater best management practices, and good operation and maintenance. At a minimum, the annual recharge from the post-development site shall approximate the annual recharge from pre-development conditions based on soil type. This Standard is met when the stormwater management system is designed to infiltrate the required recharge volume as determined in accordance with the Massachusetts Stormwater Handbook.

- The South Coast Rail project has been designed to fully comply with Standard 3.
- ESSD techniques and LID features have been incorporated into the design of each station site and layover facility. ESSD techniques incorporated in the project include reducing impervious area by removing unnecessary pavement, maintaining existing drainage patterns, and maintaining existing mature vegetation. LID features include disconnecting runoff from impervious surfaces, using sheet flow and surface conveyances as opposed to closed drainage systems, promoting groundwater recharge through bioretention and infiltration basins.
- Groundwater recharge requirements have been met for each project element.

4. Stormwater management systems shall be designed to remove 80% of the average annual post-construction load of Total Suspended Solids (TSS). This Standard is met when (1) Suitable practices for source control and pollution prevention are identified in a long- term pollution prevention plan, and thereafter are implemented and maintained; (2) Structural stormwater best management practices are sized to capture the required water quality volume determined in accordance with the Massachusetts Stormwater Handbook; and (3) Pretreatment is provided in accordance with the Massachusetts Stormwater Handbook.

- The South Coast Rail project has been designed to fully comply with Standard 4.
- Structural practices such as deep sump catch basins with hoods, oil/grit separators, gravel and grass filter strips, vegetated swales, and sediment forebays have been incorporated as appropriate in each site design in order to provide pretreatment of stormwater flows. Bioretention swales, bioretention basins, and infiltration basins have been incorporated as appropriate in each site design to provide treatment that meets or exceeds the 80 percent TSS removal requirement.
- The only location where the water quality volume and 80 percent TSS removal requirement could not be met was along the Hockomock Swamp Trestle. As described in Section 4.17.3.3, runoff from the trestle would be treated to the extent practicable and meets all of the requirements of the *de minimis* standard described in Volume 3 of the Massachusetts Stormwater Handbook.
- In order to comply with the on-going requirements of this standard, a long-term pollution prevention plan would be required as part of final design.

5. For land uses with higher potential pollutant loads, source control and pollution prevention shall be implemented in accordance with the Massachusetts Stormwater Handbook to eliminate or reduce the discharge of stormwater runoff from such land uses to the maximum extent practicable. If through source control and/or pollution prevention all land uses with higher potential pollutant loads cannot be completely protected from exposure to rain, snow, snow melt, and stormwater runoff, the proponent shall use the specific structural stormwater BMPs determined by the Department to be suitable for such uses as provided in the Massachusetts Stormwater Handbook. Stormwater discharges from land uses with higher potential pollutant loads shall also comply with the requirements of the Massachusetts Clean Waters Act, MGL c. 21, §§ 26-53 and the regulations promulgated thereunder at 314 CMR 3.00, 314 CMR 4.00 and 314 CMR 5.00.

- The South Coast Rail project has been designed to fully comply with Standard 5.
- Three elements of the project qualify as LUHPPLs: North Easton Station, Weaver's Cove East Layover Facility, and Wamsutta Layover Facility. In accordance with the requirements of Standard 5, these sites incorporate specific structural stormwater BMPs such as deep sump catch basins with hoods, oil/grit separators and sediment forebays. The layover facilities also incorporate drip pans beneath the layover tracks to catch drips or spills from the trains stored at the facility.
- Appropriate source control and pollution prevention measures must be documented in a post-construction SWPPP. This plan would be completed in conjunction with the Notice of Intent for authorization under the NDPES Multi-Sector General Permit, prior to stormwater discharges from the layover facilities.

6. Stormwater discharges within the Zone II or Interim Wellhead Protection Area of a public water supply and stormwater discharges near or to any other critical area require the use of the specific source control and pollution prevention measures and the specific structural stormwater best management practices determined by the Department to be suitable for managing discharges to such areas as provided in the Massachusetts Stormwater Handbook. A discharge is near a critical area, if there is a strong likelihood of a significant impact occurring to said area, taking into account site-specific factors. Stormwater discharges to Outstanding Resource Waters and Special Resource Waters shall be removed and set back from the receiving water or wetland and receive the highest and best practical method of treatment. A "storm water discharge" as defined in 314 CMR 3.04(2)(a)1 or (b) to an Outstanding Resource Water or Special Resource Water shall comply with 314 CMR 3.00 and 314 CMR 4.00. Stormwater discharges to a Zone I or Zone A are prohibited unless essential to the operation of a public water supply.

- The South Coast Rail project has been designed to fully comply with Standard 6.
- Stormwater discharges to ORWs would receive treatment and would be set back from the receiving water to the maximum extent practicable. Discharges to ORWs are limited to locations along the Hockomock Swamp Trestle and along track segments located near vernal pools. Typical details for stormwater treatment measures are described in Section 4.17.3.3. No discharges are proposed within a Zone 1 or Zone A of a public water supply.
- Selection of appropriate treatments for each location would occur during final design as part of detailed grading plans and drainage analysis.

7. A redevelopment project is required to meet the following Stormwater Management Standards only to the maximum extent practicable: Standard 2, Standard 3, and the pretreatment and structural best management practice requirements of Standards 4, 5, and 6. Existing stormwater discharges shall comply with Standard 1 only to the maximum extent practicable. A redevelopment project shall also comply with all other requirements of the Stormwater Management Standards and improve existing conditions.

- The South Coast Rail project has been designed to fully comply with Standard 7.
- According to the guidance in the Massachusetts Stormwater Manual, all of the station sites, except for North Easton Station, Taunton Depot Station, Freetown Station, and both of the layover facilities, qualify as redevelopment projects. Redevelopment of station sites where new parking lots are proposed (Raynham Park and Taunton) have been designed to fully comply with all of the Stormwater Standards. The Weaver's Cove East Layover Facility has also been designed to fully comply with all of the Stormwater Standards.

8. A plan to control construction related impacts including erosion, sedimentation and other pollutant sources during construction and land disturbance activities (construction period erosion, sedimentation, and pollution prevention plan) shall be developed and implemented.

- The South Coast Rail project would fully comply with Standard 8.
- The project would obtain coverage under the NPDES Construction General Permit prior to the start of earthmoving activities. A construction-period SWPPP would be developed during final design as part of the Notice of Intent submittal. Recommended construction period BMPs have been described in the DEIS/DEIR.

9. A long-term operation and maintenance plan shall be developed and implemented to ensure that stormwater management systems function as designed.

- The South Coast Rail project would fully comply with Standard 9.
- MassDOT would develop a detailed O&M Plan during final design as part of the Notice of Intent submittal.

10. All illicit discharges to the stormwater management system are prohibited.

- The South Coast Rail project would fully comply with Standard 10.
- Proposed stations and layovers have been designed so that they are in full compliance with current standards. In locations where previous development has occurred, storm drainage structures remaining from those developments would be removed within the redevelopment area. New sanitary facilities at the two layover facilities would be designed in accordance with the sanitary code.
- No statement is made with regard to existing drainage systems in portions of project sites which are not included in the redevelopment project area.

4.18 COASTAL ZONE AND CHAPTER 91

4.18.1 Introduction

This chapter identifies the potential impacts that may result from implementation of each of the proposed South Coast Bail Alternatives (see Figure 4.18-1 and Figure 4.18-2 for illustrations of the Stoughton Alternative and the Whittenton Alternative, respectively) to coastal zone resources and jurisdictional tidelands and navigable rivers and streams. Coastal zone resources are those identified in the Coastal Zone Management Act (CZMA) of 1972, as amended (16 U.S.C. 1451 et seq.), which provides for management of the nation's coastal resources and balances economic development with environmental conservation. Resources addressed under the CZMA include coastal development, water quality, public access, habitat protection, energy facility siting, ocean governance and planning, coastal hazards, and climate change.

The Massachusetts Coastal Zone Management Plan and regulations implement the federal CZMA. The Massachusetts Coastal Zone Management Act (MGL Chapter 21A, Sections 2 and 4A) established local authority to implement the Massachusetts Coastal Zone Management Plan (CZMP) through regulations at 301 CMR 20.00 through 301 CMR 25.00. This chapter assesses the consistency of the South Coast Rail project with the Massachusetts Coastal Zone Management Program (MCZMP) in accordance with regulations at 301 CMR 21.00 (federal consistency certification).

This chapter also assess impacts to tidelands and navigable rivers and streams subject to jurisdiction under M.G.L) Chapter 91, as implemented by 310 CMR 9.00 (collectively Chapter 91). Chapter 91 seeks to preserve and protect the rights of the public, and to guarantee that private uses of tidelands and waterways serve a proper public purpose. In addition to the state-level Chapter 91 requirements, Section 10 of the Rivers and Harbors Act also provides federal (USACE) jurisdiction over alterations to navigable waters of the United States.

This chapter includes descriptions of each resource, the regulatory context and significance of each, and a description of the existing resources present within the project area potentially affected by the alternatives.

Work required to implement the project within the jurisdiction of MGL Chapter 91 and the Massachusetts Coastal Zone includes track and signal system upgrades, bridge and abutment replacement, construction of stations and layover facilities. As each alternative may require some approvals within each of these jurisdictions, depending on MassDEP determinations, the following sections summarize the potential regulatory approvals and describe potential effects to Chapter 91 resources and the Massachusetts Coastal Zone.

Coastal zone and Chapter 91 resources are depicted in Figures 4.18-3 through 4.18-19. These figures illustrate the alignment alternatives from the Canton Junction Station in the north to Fall River and Bedford in the south.

The Secretary's certificate on the DEIR included the following requirements related to coastal zone:

- [For layover facilities] "Consistency with Chapter 91 licensing requirements and requirements for location within a Designated Port Area (DPA) should be described as applicable. The FEIR should clarify whether any facility located in a DPA can be allowed as a temporary and/or supporting DPA use."

- "The FEIR should clarify, and depict on figures/plans, any filled or flowed tidelands on or near the proposed layover facilities. Where applicable, information to support a Public Benefit Determination should be included."

- "The FEIR should include measures [at the proposed Whale's Tooth Station] to avoid and minimize non-point source pollution from idling trains and describe how the station site will be designed to be compatible with existing industrial uses in the New Bedford/Fairhaven Designated Port Area (DPA)."

- "The Wamsutta layover alternative is located adjacent to the Whale's Tooth Station site and the DPA. The FEIR should address compatibility issues with regard to coastal zone protection and DPA uses as recommended by CZM."

- "The proposed stations in Fall River are located near the Mount Hope Bay DPA and the Fall River station is partially located within the coastal zone. ... In consideration of sea level rise, the FEIR should consider a margin of safety to avoid a facility being located in a future elevated Zone A floodplain."

- "The FEIR should address pollution prevention and low impact development at all station and layover sites as well as project consistency with DPA uses and the Fall River City's harbor planning goals for pedestrian reconnection to the Waterfront."

- "MassDOT should consult with MassDEP and provide more detailed plans to determine whether or not the filled tidelands at Fall River Battleship Cove Station, New Bedford Whale's Tooth Station, and Wamsutta Layover facility are considered landlocked tidelands as defined at 301 CMR 9.02."

- "The FEIR should include analysis and mitigation as applicable to support a Public Benefits Determination consistent with Chapter 168 of the Acts of 2007."

- "The FEIR should describe any public access restrictions to the shoreline that may result from construction of layover facilities or other components of the proposed project."

- "Mitigation plans should be included in the FEIR to compensate for any public access impacts."

- "The FEIR should include detailed information describing the nature of the tidelands affected and the public benefits of the proposed project in accordance with the Public Benefits Determination Requirements at 301 CMR 13.00."

- "MassDOT should consult with DEP concerning the layover facility at Weaver's Cove [relative to filled tidelands] and provide DEP with the information outlined in its comment letter."

- "The FEIR should include an update on consultations and jurisdictional determinations."

- "The FEIR should identify and describe all components of the project requiring Chapter 91 licensing and whether project components are considered water-dependent or non-water dependent."

- "The FEIR should describe in detail how the project will meet licensing standards."
- "The FEIR should explain how the project is consistent with the New Bedford and Fall River Municipal Harbor Plans pursuant to 310 CMR 9.34, including how intermodal connections to the ferry service would be achieved."
- "The FEIR should explain how railroad components subject to licensing will preserve or enhance navigational capacity and maintain or enhance public access pursuant to 310 CMR 9.35 and 9.36."
- "If navigation or public access is impacted by the project, the FEIR should include detained mitigation plans."
- "The FEIR should explore opportunities on or near the layover facilities where MassDOT can 'take reasonable measures to provide open space for active or passive recreation at the water's edge'."

4.18.2 Regulatory Framework

4.18.2.1 Coastal Zone Management

Section 307(c) of the Coastal Zone Management Act of 1972, as amended (16 U.S.C. 1456(c)) requires federal agencies conducting activities, including development projects, directly affecting a state's coastal zone, to comply to the maximum extent practicable with an approved state coastal zone management program. The Act also requires any non-federal applicant for a federal license or permit to conduct an activity affecting land or water uses in the state's coastal zone to furnish a certification that the proposed activity will comply with the state's coastal zone management program. Generally, no permit will be issued until the state has concurred with the non-federal applicant's certification.

The Massachusetts Coastal Zone Management Program (MCZMP) is the state-delegated authority established by the Federal Coastal Zone Management Act of 1972. Massachusetts General Law Chapter 21, Sections 2 and 4A establishes the Commonwealth's authority to require a Federal Consistency Certification (Coastal Zone Consistency) for certain projects requiring federal action that can reasonably be expected to affect the resources or land or water uses of the Massachusetts Coastal Zone. Certification is obtained through agency confirmation that projects subject to review are consistent with the regulatory policies and management principles established by the approved Massachusetts Coastal Zone Management Program. State agency certification is required prior to federal actions by the Department of the Army under Section 404 of the Clean Water Act or Section 10 of the Rivers and Harbors Act.

The MCZMP has the jurisdictional mandate to review activities in accordance with the Massachusetts Coastal Zone Management Regulations at 301 CMR 21.00 for consistency with the program policies enumerated in the regulations at 301 CMR 21.98 and the MCZMP. The geographic scope of this program is the Massachusetts Coastal Zone established by 301 CMR 21.99, 1972, as amended (16 U.S.C. 1451 et seq.) and 15 CFR 930, as amended. The Coastal Zone Management Program also protects the limited capacity to site water-based industrial and other maritime facilities within previously developed port areas.

The Massachusetts Coastal Zone includes the entire Massachusetts coastline extending from the seaward limit of state jurisdiction to point 100 feet landward of the first major transportation infrastructure adjacent to the coast. The precise boundary is defined by the regulations at 301 CMR 21.00 (Coastal Zone Management Program Federal Consistency Review Procedures). The Federal Coastal Zone Management Act requires state certification that applicable projects requiring federal actions are consistent with the approved coastal zone management plan. Federal consistency certification of the project is required prior to issuance of a Department of the Army permit.

Coastal Zone limits presented in this chapter were determined using GIS data provided by MassGIS. The Coastal Zone limits are illustrated on Figures 4.18-11 through 4.18-19. Section 4.18.6 demonstrates the project's consistency with the MCZMP.

4.18.2.2 Section 10 of the Rivers and Harbors Act of 1899.

Section 10 of Rivers and Harbors Appropriation Act of 1899, (33 U.S.C. 403) requires a Department of the Army permit for structures and/or work in or affecting navigable waters of the United States. In the case of South Coast Rail, the Taunton River is a tidal navigable water of the United States up to the South Street East Bridge in Taunton, and the Mill River in Taunton is navigable to Spring Street in Taunton. Should the South Coast Rail proposal involve any placement of structures or work (except bridges) in or affecting the Taunton or Mill Rivers, it will be necessary for MassDOT to obtain Department of the Army authorization under Section 10, in addition to the authorization to discharge dredged or fill material under Section 404 of the Clean Water Act.

In addition, Section 9 of Rivers and Harbors Appropriation Act of 1899, (33 U.S.C. 401) prohibits the construction of any dam or dike across any navigable water of the United States in the absence of Congressional consent and approval of the plans by the Chief of Engineers and the Secretary of the Army. Section 9 also pertains to bridges and causeways but the authority of the Secretary of the Army and Chief of Engineers with respect to bridges and causeways was transferred to the Secretary of Transportation under the Department of Transportation Act of October 15, 1966. As of that date, the construction or alteration of any bridge across any navigable water of the United States requires a permit from the U.S. Coast Guard. Therefore, it will be necessary for MassDOT to obtain a bridge permit from the U.S. Coast Guard for alteration or replacement of the bridge crossings over the Taunton River for the Whittenton Alternative, and over both the Taunton and Mill Rivers for the Stoughton Alternative. The Whittenton route also crosses the Mill River; however, that crossing is located well upstream of its navigable limits, and therefore a bridge permit from the U.S. Coast Guard would not be required for the Whittenton route crossing of the Mill River).

The Corps does not have authority over bridges under Sections 9 or 10 of the Rivers and Harbors Act of 1899. Corps authority over bridges is limited to appurtenant structures such as abutments and bank stabilization, the construction of which may involve discharges of dredged or fill material, and as such are regulated under Section 404 of the Clean Water Act.

4.18.2.3 Chapter 91–Waterways Regulations

Massachusetts General Law Chapter 91 is the modern codification of a series of statues which preserve certain rights in tidelands for the citizens of the Commonwealth. These rights date to the Massachusetts Colonial Ordinances of 1641-1647 and preserve the rights of the public to fish, fowl and navigate within all tidal waters of the Commonwealth up to and including the natural high water mark. With relatively

few legislative exceptions, these rights are preserved in perpetuity for the citizens of the Commonwealth.

Compliance with Chapter 91 is administered by the Massachusetts DEP through the Waterways Regulations at 310 CMR 9.00. These regulations establish procedures for the issuance of licenses for activities and structures located within jurisdictional areas. Maintenance, repair and minor modifications to existing, authorized structures within a jurisdictional area may be permitted without a new license or license amendment under the procedures at 310 CMR 9.22.

As it relates to this project, Chapter 91 jurisdiction potentially extends to four key components:

- non-tidal rivers and streams;
- tidal waters (flowed tidelands);
- filled tidelands; and
- landlocked tidelands.

4.18.2.4 Non-Tidal Rivers and Streams

The Waterways Regulations at 310 CMR 9.04(1)(e) establish Chapter 91 jurisdiction over the following:

> (e) any non-tidal river or stream on which public funds have been expended for stream clearance, channel improvement, or any form of flood control or prevention work, either upstream or downstream within the river basin, except for any portion of any such river or stream which is not normally navigable during any season, by any vessel including canoe kayak, raft or rowboat; The Department [DEP] may publish, after opportunity for public comment and review, a list of navigable streams and rivers….

This regulation establishes Chapter 91 jurisdiction over any navigable river or stream to which public funds have been expanded. To date, the Massachusetts DEP has not published a list of navigable rivers and streams in the Commonwealth, and neither MassDOT nor MassDEP is aware of a definitive list of non-tidal rivers and streams upon which public funds have been spent. In the absence of such a list, MassDEP states in their comment letter on the DEIS/DEIR:

"As a general rule … only the non-navigable uppermost reaches of a river basin are not subject to review."

Therefore, in order to determine the jurisdictional status of non-tidal rivers and streams, this evaluation considered the potential navigability of each river, stream, or wetland crossing within the rail corridor. The following materials were relied upon in assessing navigability:

- Stream order as determined by reference to USGS maps and "StreamStats;" using the Strahler method;
- Presence of a defined channel upstream and/or downstream of the crossing;
- Upstream and downstream conditions in terms of density of vegetation or the presence of culverts or other obstructions to navigation;

- Available survey data; and
- Field observations.

Existing and planned transportation improvements within areas potentially subject to jurisdiction under Chapter 91 pursuant to 310 CMR 9.04 were reviewed and preliminary determinations made regarding jurisdiction. These preliminary determinations are based in part on written and verbal guidance provided by MassDEP. MassDEP has the sole authority for making such determinations under Chapter 91.

4.18.2.5 Tidal Waters (Flowed Tidelands)

The Massachusetts Waterways Regulations at 310 CMR 9.02 define Flowed Tidelands as "…present submerged lands and tidal flats which are subject to tidal action." Flowed tidelands presented in this chapter are based on GIS data provided by MassGIS and Massachusetts DEP.

4.18.2.6 Filled Tidelands

The Massachusetts Waterways Regulations at 310 CMR 9.02 define filled tidelands as "former submerged lands and tidal flats which are no longer subject to tidal action due to the presence of fill."

The jurisdictional boundaries of filled tidelands are defined by the Historic High Water Mark, which is defined by 310 CMR 9.02 as:

> The high water mark which existed prior to human alteration of the shoreline by filling, dredging, excavating, or other means. In areas where there is evidence of such alteration by fill, the Department shall presume the historic high water mark is the farthest landward former shoreline which can be ascertained with reference to topographic of hydrographic surveys…

Filled tidelands presented in this chapter are based on GIS data provided by DEP.

4.18.2.7 Landlocked Tidelands

The Waterways Regulations define landlocked tidelands in 310 CMR 9.02 as:

> Any filled tidelands which on January 1, 1984 were entirely separated by a public way or interconnected public ways from any flowed tidelands, except for that portion of such filled tidelands which are presently located:
>
> (a) within 250 feet of the high water mark, or
>
> (b) within any Designated Port Area. Said public way or ways shall also be defined as landlocked tidelands, except for any portion thereof which is presently within 250 feet of the high water mark.

4.18.2.8 Designated Port Areas

The Chapter 91 and Coastal Zone Programs overlap in the case of nonwater-dependent use projects and activities proposed within Designated Port Areas (DPA) established by 301 CMR 25.00. New nonwater-dependent use projects are not permitted within DPAs except on a limited basis and without significant

detriment to the capacity of the DPA to accommodate water-dependent industrial uses in the future [310 CMR 9.32(b)]. More information regarding DPAs is provided in the Coastal Zone Management section of this chapter.

4.18.2.9 Chapter 91 Licensing Requirements

Chapter 91, Section 12A authorizes DEP to license and prescribe the terms for the construction or extension of a dam, road, bridge or other structure, or the filling of land, the driving of piles, or the making of excavations, in, over or upon the waters below high water mark of any river or stream within the commonwealth with respect to which expenditures from federal, state or municipal funds have been made for stream clearance, channel improvement or any form of flood control or prevention work, and the provisions of this chapter shall apply to all such licenses."

Massachusetts General Law Chapter 91, Section 18B as established by the Statute 2007, Chapter 168, Section 8 reaffirms this exception from licensing for filled tidelands and requires the Secretary for Energy and Environmental Affairs to issue a Public Benefit Determination for projects in landlocked tidelands within 30 days of the issuance of a final MEPA certificate pursuant to 301 CMR 13.00.

The Waterways Regulations do not require a new license or license amendment for the continued use, maintenance or minor modifications to existing, authorized fill or structures within jurisdictional areas, provided that the proposed work does not include a substantial enlargement of the existing structures or fill and the structures have been in existence since January 1, 1984.

The jurisdictional resources are further described below. New nonwater-dependent use projects are permitted on a limited basis within Designated Port Areas (DPA) if, among other instances, the project constitutes a supporting DPA use as defined at 310 CMR 9.02 as pursuant to the waterways regulations at 310 CMR 9.32(1) (b) (4). Furthermore, as confirmed by MassDEP in their comment letter on the Draft EIS/EIR, "replacement, reconstruction or other modification" to existing railroad beds is allowed, even in a Designated Port Area, provided there is limited net encroachment per 310 CMR 9.31(2)(b) and (c). A detailed description of DPAs is provided later in this chapter.

In the case of landlocked tidelands, no license is required under 310 CMR 9.00, but the Secretary for Energy and Environmental Affairs is required to issue a Public Benefits Determination under 301 CMR 13.00.

The Waterways Regulations require a license for all construction activities, placement of fill and changes in use within present and former tidelands and the navigable portions of non-tidal rivers and streams when such streams have been improved through the expenditure of public funds for stream clearance, channel improvement or flood control upstream or downstream of the proposed work. The DEP, following review of a completed application and plans and a public comment period, issues licenses for proposed construction, placement of fill or changes in use. The proposed project is regulated under Chapter 91 as an infrastructure crossing facility. The regulations at 310 CMR 9.12 require the Secretary of Energy and Environmental Affairs to make a determination of water dependency for the project. Such a finding of water dependency is anticipated for the bridges based on geography alone.

Any project element requiring a new license must meet the applicable basic requirements established by 310 CMR 9.32 through 9.54. Table 4.18-1 lists the basic licensing requirements.

Table 4.18-1 Compliance with Basic Requirements Listed in 310 CMR 9.31(1) for Non-Tidal Rivers and Streams

Requirement in 310 CMR 9.31(1)	Referenced Regulation	Requirement Description	Standard	Applicability / Compliance
(a)	310 CMR 9.32	Categorical restrictions on fill and structures	No new fill is permitted in flowed tidelands for non-water dependent use projects.	All existing and proposed crossings are water dependent infrastructure crossing facilities pursuant to 310 CMR 9.02 and 310 CMR 9.12(2)(d).)
(b)	310 CMR 9.33	Environmental protection standards	Projects must comply with all applicable state environmental protection requirements.	The project would obtain all required state and federal permits and approvals.
(c)	310 CMR 9.34	Conformance with municipal zoning and harbor plan	Projects must comply with applicable local zoning.	MassDOT is not subject to local zoning.
			Projects must comply with applicable Municipal Harbor Plans (MHP)	The project complies with the plans and recommendations of the approved New Bedford/Fairhaven MHP as described in Section 4.18.6.5. The project is consistent with the Fall River Harbor and Downtown Economic Development Plan as described in Section 4.18.6.5.
(d)	310 CMR 9.35(2)	Standards to preserve water-related public rights: Public Rights Applicable to All Waterways	This standard prohibits projects from significantly interfering with: Public rights of navigation which exist in all waterways; Free passage over and through the water; and Access to town landings.	Existing culverts crossing non-tidal rivers and streams provide limited navigation. The existing bridges are generally licensed structures and provide passage for small vessel navigation. Proposed culvert and bridge improvements would maintain or enhance existing navigability at jurisdictional crossings. Table 4.18-2 lists individual non-tidal river and stream crossings and describes the potential effect on public rights to navigation and free passage over and through the water.

Requirement in 310 CMR 9.31(1)	Referenced Regulation	Requirement Description	Standard	Applicability / Compliance
(d)	310 CMR 9.35(3)	Standards to preserve water-related public rights: Public Rights Applicable to Tidelands and Great Ponds	Projects "shall not significantly interfere with public rights of fishing and fowling which exist in tidelands and Great Ponds…" Projects shall not significantly interfere with on-foot passage and in the case of non-water dependent use projects shall include accommodations for public access across the site.	The project does not include any work within existing flowed tidelands or Great Ponds and therefore would not interfere with such public rights.
(d)	310 CMR 9.35(4)	Compensation for Interference with Public Rights in Commonwealth Tidelands and Great Ponds	Any water dependent use projects which include fill or structures for private use of Commonwealth tidelands shall provide compensation to the public for interfering with its broad rights to use such lands for any lawful purpose.	The project is a public infrastructure project as defined at 310 CMR 9.02 and therefore does not include any fill or structures for private use of Commonwealth Tidelands of Great Ponds.
(d)	310 CMR 9.35(5)	Management of Areas Accessible to the Public	Any project which includes tidelands or Great Ponds accessible to the public shall provide for long-term management of such areas which achieves effective public use and enjoyment while minimizing potential conflicts with other legitimate uses.	The project does not include any tidelands or Great Ponds accessible to the public.
(e)	310 CMR 9.36(1)	Standards to protect water-dependent uses	The Project shall preserve the availability and suitability of tidelands, Great Ponds and other waterways that are in use for water-dependent purposes, or which are reserved primarily as locations for maritime industry or other specific types of water-dependent use.	See 310 CMR 9.36(2) through (5) below

Requirement in 310 CMR 9.31(1)	Referenced Regulation	Requirement Description	Standard	Applicability / Compliance
(e)	310 CMR 9.36(2)		The project shall not significantly interfere with littoral or riparian property owners' rights to approach their property from a waterway and to approach the waterway from said property.	The project does not include any new non-tidal river and stream crossings and would therefore not significantly interfere with any littoral or riparian property owners' rights of access. Existing crossings would be maintained or upgraded to support passenger rail traffic. Where feasible, upgrades will widen culverts to improve wildlife passage resulting in a net benefit to navigation.
(e)	310 CMR 9.36(3)		The project shall not significantly disrupt any water-dependent use in operation, as of the date of license application, at an off-site location proximate to the vicinity of the project site.	The project would enhance the capacity for the existing water-dependent infrastructure crossing facilities to support public transportation and this public service project.
(e)	310 CMR 9.36(4)		The project shall not displace any water-dependent use that occurred on the site within the last five (5) years.	The existing railroad crossings are all located on land owned and/or operated as a railroad for many years. The project would restore, maintain or enhance these existing water-dependent infrastructure crossing facilities only water dependent use.

A determination of water dependency is an important part of demonstrating the project's compliance with Chapter 91 because water-dependent use projects are presumed to meet the proper public purpose requirement and may allow DEP to issue individual licenses without a public hearing, if appropriate, expediting the approval process in these instances.

Many of the existing bridges and track over non-tidal rivers and streams lack existing licenses for one of three reasons:

- The waterbody is not subject to Chapter 91 and therefore no license is required;
- The bridge and associated fill and structures were authorized by act of the Massachusetts General Court in chartering the original railroad;
- They were built prior to the promulgation of 310 CMR 9.00 and did not require a license.

The regulations at 310 CMR 9.22 provide a regulatory mechanism to authorize several categories of maintenance, repair and minor modification to existing authorized structures since January 1, 1984. These are:

- **Maintenance and Repair**–defined by 310 CMR 9.22(1) as including but not limited to: replacement of railroad track, stabilization of road or rail beds, reconstruction of culverts and catch basins, and other maintenance or repair of existing public transportation facilities and associated drainage systems, as necessary to preserve or restore the serviceability of such facilities for the original use, provided that maintenance and repair shall not include substantial enlargement of such facilities, such as roadway widening, adding shoulders, or upgrading intersections.

This is interpreted to mean that repair, replacement and maintenance activities may be permitted to restore the serviceability of the tracks, bridges, culverts, etc. provided the work does not include addition of new tracks within the jurisdictional area not contemplated by the original license.

- **Minor Project Modification**–defined by 310 CMR 9.22(3) to include: Structural alterations which are confined to the existing footprint of fill and structures being altered and which represent an insignificant deviation from the original license specifications in terms of size, configuration, materials or other relevant design or fabrication parameters.

In the case of authorized jurisdictional crossings that are determined by DEP to be jurisdictional, minor modifications may typically be obtained for work that a) reduces or maintains the footprint of existing fill or structures; and b) maintains or increases the space available for navigation.

4.18.2.10 Designated Port Areas

The 1978 MCZMP identified twelve Designated Port Areas (DPA) within existing developed harbors in Massachusetts coastal communities. The stated purpose for identifying these areas was to establish specific developed ports that are uniquely suited to host marine-based commercial and industrial activities.

The MCZMP establishes state policies recognizing the unique characteristics of the designated port areas and seeks to protect them from pre-emption by uses that are nonwater-dependent uses through the

federal consistency certification process created by the MCZMP and the standards for nonwater-dependent use projects subject to Chapter 91. The regulations at 301 CMR 25.00 formalize the boundaries of the DPAs and establish specific procedures for periodic review and adjustment. There have been several adjustments to the DPAs since 1978, including the elimination of the Plymouth Cordage DPA and other changes.

The Chapter 91 and Coastal Zone Programs overlap in the case of nonwater-dependent use projects and activities proposed within Designated Port Areas (DPA) established by 301 CMR 25.00. Nonwater-dependent use projects are not permitted within DPAs except on an interim basis without significant detriment to the capacity of the DPA to accommodate water-dependent industrial uses in the future.

The location of Chapter 91 resources, Massachusetts Coastal Zone and Designated Port Areas used in this chapter were provided by MassGIS, Massachusetts DEP and Massachusetts Office of Coastal Zone Management.

4.18.3 Existing Conditions

4.18.3.1 Non-Tidal Rivers and Streams

The jurisdictional review of non-tidal rivers and streams conducted for this FEIS/FEIR considered all culvert and bridge crossings in the project corridor to confirm the presence of a watercourse at each crossing. There are 139 bridges or culverts along the corridor. Culverts that convey drainage under public roads, stormwater in upland areas, and drainage parallel to the tracks were eliminated from further review because they have no potential for navigability. After eliminating these from consideration, 42 crossings of rivers and streams along the right-of-way were considered further for potential Chapter 91 jurisdiction. Table 4.18-2 lists the 42 crossings and provides the rationale for the Chapter 91 jurisdictional determination. Based on this analysis, there are 24 Chapter 91 jurisdictional waterway crossing locations, consisting of 15 bridges and 9 culverts. Figures 4.18.3 through 4.18.19 show the locations of these structures as well as the 25 structures not subject to Chapter 91 licensing.

4.18.3.2 Tidal Waters (Flowed Tidelands)

No work for the South Coast Rail project is proposed within flowed tidelands.

4.18.3.3 Filled Tidelands

The South Coast Rail project includes the reconstruction of track, ballast, bridges and culverts within filled tidelands and the construction of two new stations and two layover facilities within filled tidelands. The location and extent of filled tidelands relative to the South Coast Rail project elements was determined by mapping the historic mean high water mark generated by the Massachusetts Chapter 91 Mapping Project as distributed by MassGIS.

Table 4.18-2 Chapter 91 Jurisdictional Status of Non-Tidal River and Stream Crossings

Milepost	Identification	Town	Name of Waterbody	Stream Order	Description	Potentially Navigable	Rationale
Stoughton Line							
0.87	Undergrade bridge for Forge Pond	Canton	Pequit Brook	3	Pond connector for Forge Pond and Kingsley Pond.	YES	stream order, horizontal and vertical clearance
1.64	Undergrade bridge for Beaver Meadow Brook [Mill Brook]	Canton	Beaver Meadow Brook	3	Perennial stream flowing east to west, connecting Beaver Meadow Brook to ponds.	YES	stream order, horizontal and vertical clearance
4.47	CV-ST 4.47	Stoughton	Unnamed tributary	1	Intermittent stream flowing east to west in developed area.	NO	dense vegetation beyond culvert upstream
6.80	Undergrade bridge for Cowessett Brook [Whitman Brook]	Easton	Whitman Brook	2	Perennial stream flowing west to east in rural area.	YES	stream order, horizontal and vertical clearance
7.23	CV-ST 7.23	Easton	Unnamed tributary to Whitman Brook	2	Intermittent stream flowing west to east in rural area.	NO	narrow shallow channel downstream and downstream precludes navigation
7.42	CV-ST 7.42	Easton	Unnamed tributary to Whitman Brook	1	Intermittent stream flowing west to east in suburban area.	NO	upstream ponding at the culvert provides limited open water, upstream channel small and shallow, downstream flow is diffuse with no defined channel
7.95	Undergrade bridge for Small Creek [Quesset Brook at Shovel Shop Pond] BRIDGE E-06-032	Easton	Quesset Brook	3	Perennial stream flowing west to east in urban area.	NO	while bridge provides adequate clearance and likely > 6 in water depth (annually), adjacent culverts downstream preclude navigation
10.95	CV-ST 10.95	Easton	Black Brook	2	Perennial stream flowing west to east in rural area.	YES	stream order and presence of open water, channel

This mapping project was a collaborative effort between DEP and the Massachusetts Office of Coastal Zone Management intended to catalog and geo-reference historic maps, charts and surveys of the Massachusetts coast to identify the earliest known shoreline that existed prior to human alteration by placement of fill, damming or other means. The resulting historic high water mark is a combination of data identifying the most likely historic shoreline for the Commonwealth. While this data does not carry statutory or regulatory authority per se, in practice, DEP presumes the historic high water mark and limits of jurisdiction generated by this project represent the oldest most credible shoreline that existed prior to human alteration.

The location of filled tidelands, Massachusetts Coastal Zone and Designated Port Areas used in this chapter were provided by MassGIS, Massachusetts DEP and Massachusetts Office of Coastal Zone Management. The location of the presumed historic high water mark and South Coast Rail project elements in filled tidelands are shown on Figures 4.18.9 through 4.18.19.

4.18.3.4 Landlocked Tidelands, and Coastal Zone and Designated Port Areas Boundaries

Figures 4.18.11 through Figure 4.18.18 depict the Coastal Zone boundaries and the DPAs present within the study area. The limits of the DPAs listed in this chapter and the Coastal Zone boundaries were determined using preliminary GIS data provided by the Massachusetts Coastal Zone Management Program. Landlocked Tidelands are identified in Figures 4.18-11, 4.18-12 and 4.18-18.

4.18.4 Impacts by Element

This chapter provides a description of each project element and outlines the known and potential jurisdictional areas subject to Massachusetts Chapter 91 and the MCZP. The two Build Alternative alignments are shown in Figure 4.18-1 (Stoughton Alternative) and Figure 4.18-2 (Whittenton Alternative). (It should be noted that Section 9 of the Rivers and Harbors Appropriation Act of 1899 (33 U.S.C. 403; Chapter 425, March 3, 1899; 30 Stat. 1151) prohibits the construction of any bridge, dam, dike or causeway over or in navigable waterways of the United States without Congressional approval (see Chapter 8, *Regulatory Compliance*). Administration of Section 9 has been delegated to the Coast Guard. Structures authorized by State legislatures may be built if the affected navigable waters are totally within one State, provided that the plan is approved by the Chief of Engineers and the Secretary of Army (33 U.S.C. 401). Section 10 of the Act prohibits the unauthorized obstruction or alteration of any navigable water of the United States. This section provides that the construction of any structure in or over any navigable water of the United States, or the accomplishment of any other work affecting the course, location, condition, or physical capacity of such waters is unlawful unless the work has been approved by the Chief of Engineers.)

The Stoughton and Whittenton Alternatives each include an electric and a diesel variant (See Chapter 2). Both alternatives would involve development along the same alignment and include the same stations and layover sites. In addition to the development of the alignment, stations and layover facilities, the electric alternatives would involve development of traction power substations, and therefore would potentially affect more Coastal Zone and Chapter 91 resources than would the diesel alternatives. As such, this chapter is focused on evaluation of the Stoughton and Whittenton Electric Alternatives as the worst-case potential impact.

4.18.4.1 No-Build (Enhanced Bus) Alternative

The No-Build Alternative would consist of enhancing current bus service along existing roads and highways. Three existing Park and Ride facilities would be modified as part of the No-Build Alternative:

- West Bridgewater Park and Ride, located near the southwest corner of the intersection of Routes 106 and 24;
- Mount Pleasant Street Park and Ride, located on the northwest corner of the intersection of King's Highway and Route 140 in New Bedford;
- Galleria Park and Ride, located adjacent to the Silver City Galleria shopping mall in Taunton.

None of the elements proposed under the No-Build Alternative are located within Chapter 91 or Coastal Zone jurisdiction. Therefore, no impacts would occur.

4.18.4.2 Southern Triangle Study Area (Common to all Build Alternatives)

The Build Alternatives use existing segments of the railroad right-of-way along the New Bedford Main Line and Fall River Secondary (together referred to as the Southern Triangle). This section describes the portions of these rail lines that are located within the coastal zone, and the portions subject to regulation under Chapter 91. The northern elements of the Build Alternatives within the coastal zone are described in subsequent sections, as are the proposed station sites and layover facilities. These resources are relative to the tidal portions of the Taunton and Acushnet Rivers, generally limited to the adjacent waters of New Bedford Inner Harbor and Mount Hope Bay.

Fall River Secondary

The existing Fall River Secondary freight track extends from Myricks Junction in Berkley to Battleship Cove in Fall River (Figure 4.18-1 and 4.18-2). The corridor crosses several areas of filled tidelands in Fall River, several non-tidal rivers and streams potentially subject to Chapter 91 and portions of the Massachusetts Coastal Zone in Freetown and Fall River.

Work includes reconstructing existing track, addition of a second track, ballast and culvert and bridge replacement. The electric alternative includes constructing an overhead catenary system to provide motive power that would be installed within the railroad right-of-way. Stations and Layovers for the Fall River Secondary are discussed in the Stations and Layover Facilities sections.

Chapter 91 Areas

The Fall River Secondary crosses approximately 4,100 feet of filled tidelands in seven locations (see Figures 4.18-14 through 4.18-19 and Table 4.18-3). Research performed in consultation with the DEP Waterways Program staff was unable to locate licenses for several locations where the track crosses filled tidelands. Because these tidelands were filled and the track was originally constructed in the 1850s, remaining in continuous use since that time, their continued use and permitted maintenance or minor modifications may be authorized under 310 CMR 9.05 provided no unauthorized structural alteration has occurred since January 1, 1984.

The Build Alternatives do not include any work within Fall River Harbor or the tidal portions of the Taunton River. The Fall River Secondary includes three non-tidal river crossings potentially subject to Chapter 91 Jurisdiction. This crossing (see Figure 4.18-14) is consistent with Chapter 91 jurisdiction because the river is navigable during certain times of year by a small boat such as a canoe or kayak. Table 4.18-4 lists the crossing and provides a summary of the jurisdictional status and rationale for the determination.

Table 4.18-3 Project Elements in Filled Tidelands: Fall River Secondary

Location ID[1]	Length (ft)	Municipality	Authorization
FR 1	840	Fall River	License not available; continued use, maintenance and minor modifications may be permitted pursuant to 310 CMR 9.05 and 310 CMR 9.22.
FR 2	1270	Fall River	
FR 3	50	Fall River	
FR 4	370	Fall River	
FR 5	160	Fall River	
FR 6	900	Fall River	
FR 7	530	Fall River	

1 See Figures 4.18-15 and 4.18-19.

Table 4.18-4 Non-Tidal River and Stream Crossings–Fall River Secondary

Waterbody	Municipality	Potentially Jurisdictional	Rationale	Presently Licensed	Anticipated Ch. 91 approval
Assonet River (Cedar Swamp River)	Lakeville	Yes	Navigable river/stream	No	New License

Coastal Zone Areas

Approximately 6.6 miles of the Fall River Secondary (in three segments) is located within the Coastal Zone (see Figures 4.18-14 through 4.18-19). A total of 0.5 mile of the Fall River Secondary near the southern end of the project area is located within the Mt. Hope Bay Designated Port Area, consisting of approximately 2,100 feet near Weaver's Cove (Figure 4.18-16) and 500 feet near Battleship Cove (Figure 4.18-18). The continued use and anticipated replacement/upgrade or enhancement of track within the Coastal Zone and DPAs is consistent with the regulatory policies of the Massachusetts Coastal Zone Management Plan. These improvements would maintain or enhance the capacity of the affected coastal zone and DPA to support marine based industry. A more detailed review of the project's compliance with the regulatory policies of the MCZMP is provided in section 4.18.6.

New Bedford Main Line

The existing New Bedford Main Line freight track extends from Weir Junction in Taunton to the State Pier in New Bedford (see Figures 4.18-1 and 4.18-2. The corridor crosses several areas of filled tidelands south of Wamsutta Street in New Bedford and eight Chapter 91 jurisdictional non-tidal rivers and streams.

Work includes reconstructing existing track, addition of a second track, ballast and culvert and bridge replacement. Electric alternatives include an overhead catenary system to provide motive power that would be installed within the railroad right-of-way. Stations and Layovers for the New Bedford Main Line are discussed in later sections.

Chapter 91 Areas

The New Bedford Main Line crosses approximately 4,300 feet of filled tidelands in four locations, all located south of Wamsutta Street in New Bedford (see Figure 4.18-13 and Table 4.18-5). These jurisdictional areas include existing track and a portion of proposed Whale's Tooth Station.

The construction of the New Bedford Main Line south of Wamsutta Street in New Bedford was originally authorized by Waterways License 166, issued on June 18, 1873 subsequent to Chapter 20 of the Acts of 1873. Review of DEP licensing records identified this license as authorizing the existing track from the Acushnet Street crossing to the terminus adjacent to Leonard's Wharf.

Table 4.18-5 Project Elements in Filled Tidelands–New Bedford Main Line

Location ID[1]	Length (ft)	Municipality	Authorization
NB 1	790	New Bedford	License 166, June 18, 1873
NB 2	1,740	New Bedford	License 166, June 18, 1873
NB 3	1,370	New Bedford	License 166, June 18, 1873
NB 4	400	New Bedford	License 166, June 18, 1873

1 See Figure 4.18-13.

The New Bedford Main Line also crosses eight non-tidal rivers and streams that are likely subject to Chapter 91 jurisdiction. These eight rivers are listed in Table 4.18-6. Of these eight crossings, a license has been identified for only the Taunton River, although it is possible that the existing track was authorized by the Massachusetts legislature as part of any of several approvals for the original construction of the track now collectively called the New Bedford Main Line.

The Waterways Regulations do not require a new license or license amendment for the continued use, maintenance or minor modifications to existing authorized fill or structures within jurisdictional areas, provided that the proposed work does not include a substantial enlargement of the existing structures or fill and the structures have been in existence since January 1, 1984.

The following sections describe the proposed work at the eight crossing and provide a summary of the potential approvals necessary under Chapter 91 and the Coastal Zone Management Program.

Taunton River—The Taunton River is a major regional river, is navigable at this crossing and is presumed to have had public funds expended for stream clearance, channel improvement and flood control. Accordingly, the river is subject to Chapter 91 jurisdiction.

The proposed work at this Taunton River Crossing (Figure 4.18-7, Tile 2) includes replacing the existing wooden pile supported trestle conveying a single track to single span concrete structure supporting two tracks. The work would remove the existing wooden piles and increase the width of the structure within areas of Chapter 91 jurisdiction. The proposed work would improve navigation by removing the existing piles supporting the four spans, but is also anticipated to reduce the space available for navigation by reducing the clearance by approximately 7.5 inches. These changes combined would likely require a new waterways license under Chapter 91.

Unnamed Tributary–Cotley River—The culvert designated CV-NB 14.52 (see Figure 4.18-8) conveys an unnamed tributary to the Cotley River beneath the right-of-way. This crossing would be replaced with a larger structure and would require a new license because (1) the replacement structure would exceed the footprint of the existing structure to accommodate a second set of tracks and (2) the right-of-way at this location does not constitute an existing public service project stipulated by 310 CMR 10.05(3)(c).

Proposed Bridge and Culvert Replacement Subject to Chapter 91

Table 4.18-6 Non-Tidal River and Stream Crossings–New Bedford Main Line

Milepost	Waterbody	Presently Licensed	Proposed Alteration	Number of Tracks Existing	Number of Tracks Future	Anticipated Chapter 91 Application
New Bedford Main Line						
11.80	Taunton River (Bridge T-01-075)	Yes	Bridge replacement: existing piles would be removed and one new cast-in-place concrete pier would be constructed in the center span. New abutments would be constructed behind existing abutments which would then be removed.	1	2	New License
14.52	Unnamed tributary to Cotley River (CV-NB 14.52)	No	Replacement/expansion of existing culvert.	1	2	New License
15.17	Cotley River (Bridge B-08-004)	No	Bridge replacement: New abutments would be constructed behind the existing abutments, which would then be removed.	1	2	New License
15.70	Cotley River (Bridge B-08-005)	No	Bridge replacement: New abutments would be constructed behind the existing abutments, which would then be removed.	1	2	New License
17.89	Unnamed tributary to Assonet River [Cedar Swamp River] (CV-NB 17.89)	No	Replacement of existing culvert, not presently designed.	1	1	Maintenance
18.60	Assonet River (Cedar Swamp)No. 1 (Bridge L-01-018)	No	Bridge replacement: existing piles to be replaced by one mid-stream concrete pier. New abutments to be constructed outside existing structure which would then be removed.	1	1	New License
21.65	Fall Brook (Bridge F-09-028)	No	Bridge replacement: new abutments would be constructed behind existing abutments, which would then be removed.	1	1	Minor modification
26.96	Unnamed (CV-NB 26.96)	No	Replacement of existing culvert, not presently designed.	1	1	Maintenance

Cotley River (1)—This Cotley River crossing (Figure 4.18-8, Tile 1) is subject to Chapter 91 jurisdiction because it is navigable during at least part of the year. The proposed work would require a new Chapter 91 license because the project includes widening the crossing from one track to two. This substantial enlargement does not typically meet the regulatory criteria for maintenance or minor modifications permitted under 310 CMR 9.22.

Cotley River (2)—This Cotley River crossing (Figure 4.18-8, Tile 2) is subject to Chapter 91 jurisdiction because it is navigable during at least part of the year. The proposed work would require a new Chapter 91 license because the project includes widening the crossing from one track to two. This substantial enlargement does not typically meet the regulatory criteria for maintenance or minor modifications permitted under 310 CMR 9.22.

Cedar Swamp River—The Cedar Swamp River crossing (Figure 4.18-9, Tile 1) is subject to Chapter 91 jurisdiction because it is navigable during at least part of the year. The proposed work would require a new Chapter 91 license because the project includes widening the crossing from one track to two and the anticipated reduction of space available for navigation by reducing of clearance beneath the bridge by an estimated 6.75 inches. This substantial enlargement does not typically meet the regulatory criteria for maintenance or minor modifications permitted under 310 CMR 9.22 and a new license would be required.

Freetown Brook—Freetown Brook, also known as Fall Brook (Figure 4.18-9, Tile 2), is jurisdictional because its approximately 50-foot cross-section would appear to make it navigable at least part of the year. The proposed work would require a new license because the project includes modifications at this location.

Unnamed Tributary to Assonet River—The culvert designated CV-NB 17.89 (see Figure 4.18-8) conveys non-tidal rivers and streams presumed to be subject to Chapter 91 jurisdiction. This culvert is planned to be replaced by similarly sized structures, presumed to meet the regulatory criteria for maintenance authorized by 310 CMR 9.22(1).

Unnamed Watercourse in Acushnet Cedar Swamp—The culvert designated CV-NB 26.96 (see Figure 4.18-10) conveys non-tidal rivers and streams presumed to be subject to Chapter 91 jurisdiction. This culvert is planned to be replaced by similarly sized structures, presumed to meet the regulatory criteria for maintenance authorized by 310 CMR 9.22(1).

Coastal Zone Areas

Approximately 1,600 feet of the project is within the Coastal Zone associated with the Acushnet River and New Bedford Harbor. This jurisdictional area is all south of Wamsutta Street where the track crosses over the John F. Kennedy Highway (Route 18) and Acushnet Avenue.

Approximately 500 feet of the project near the southern end of the New Bedford Main Line is located within the New Bedford/Fairhaven DPA. The DPA boundary is approximately 70 feet east of the proposed Whale's Tooth Station. The location and extent of this DPA is shown on Figures 4.18-11 and 4.18-12. Work proposed within the DPA is limited to reconstruct the "tail track" south of the station, which would allow trains to access Whale's Tooth Station. These activities are consistent with the regulatory policies of the Massachusetts Coastal Zone Management Plan because they maintain or support the future use of this rail corridor as an accessory use to existing and potential water-dependent marine industrial uses within the DPA. A more detailed review of the project's compliance with the

Massachusetts Coastal Zone Management Plan is presented in Section 4.18.6. Work within the Massachusetts Coastal Zone, including this DPA, will require a Federal Consistency Certification by the Massachusetts Coastal Zone Management Program.

Northeast Corridor

The existing Northeast Corridor would be used for the Build Alternatives from Boston's South Station to Canton Junction. The existing double-track line supports both electric- and diesel-powered regional freight and passenger service. The Build Alternatives would use existing infrastructure between South Station and Canton Junction, and as such, would not involve new construction.

Stoughton Electric Alternative

Chapter 91 Areas

The Stoughton Electric Alternative uses existing rail corridors that were previously developed connecting the Northeast Corridor with the New Bedford Main Line. The existing right-of-way extends from Canton Junction in Canton to Weir Junction in Taunton (see Figures 4.18-1 and 4.18-2). The track from Canton Junction to Stoughton Station is presently an active passenger rail corridor. South of Stoughton Station, the railroad right-of-way remains largely intact; however, most of the track and ballast have been removed and the condition of the culverts and bridges varies. Work proposed within this corridor includes new track, ballast, culvert and bridge replacement, and in the case of electric alternative, an electric centenary system within the right-of-way to provide electric motive power.

The South Coast Rail project elements subject to licensing and therefore required to comply with 310 CMR 9.37(2) include certain non-tidal river and stream crossings. The majority of the non-tidal river and stream crossings is not adjacent to the shoreline and would not be expected to be subject to inundation due to a sea level rise of up to the 16 inches predicted by 2050. There are 13 crossings of non-tidal rivers that are subject to Chapter 91. See Table 4.18-7 for a listing of these crossings. The following section describes the work proposed at Forge Pond, Taunton River and Mill River crossings and summarizes the Chapter 91 jurisdiction.

Kingsley Pond/Forge Pond—The existing ballasted stone arch bridge spanning this hydraulic connection between Kingsley and Forge Ponds (Figure 4.18-3) would be replaced by a single span concrete structure supporting two tracks. While the alternatives using the Stoughton Line would require a second set of tracks, the proposed work is not anticipated to substantially expand the footprint of the structure. The proposed design is expected to be completed without the placement of any new fill within the waterway and without substantially reducing the space available for navigation. If these criteria can be met within the footprint of the existing structure, the work could be approved as maintenance or a minor project modification under the regulations at 310 CMR 9.22.

Beaver Meadow Brook—The Beaver Meadow Brook (Figure 4.18-3) crossing was designed to accommodate two tracks but presently contains only a single track supported by an historic arch bridge. The project includes the construction of a new span over the waterway supported by the existing abutments. A new license would be required because the work would constitute a substantial structural alteration defined at 310 CMR 9.02. While the crossing has not yet been designed, the additional span over the Beaver Meadow Brook would approximately double the footprint of structure over this waterbody.

Table 4.18-7 Proposed Bridge and Culvert Replacement Subject to Chapter 91–Stoughton Line

Milepost	Waterbody	Presently Licensed	Proposed Alteration	Number of Tracks Existing	Number of Tracks Future	Anticipated Chapter 91 Application
Stoughton Line						
0.87	Pequit Brook [Forge Pond]	No	No change to historic arch structure. Addition of second track, expansion of footprint over waterway, no change in navigability.	1	2	New License
1.64	Beaver Meadow Brook	No	No change to abutment location. New structure proposed above or adjacent to existing historic arch.	1	2	New License
6.80	Cowessett Brook [Whitman Brook]	No	New abutments would be constructed behind existing abutments, which would then be removed.	1	1	Maintenance
10.95	Black Brook (CV-ST 10.95)	No	Replacement of existing culvert, not presently designed.	1	1	Maintenance
11.59	Unnamed tributary to Black Brook (CV-ST 11.59)	No	Replacement of existing culvert, not presently designed.	1	1	Maintenance
12.68	Black Brook (CV-ST 12.68)	No	New bridge would be constructed to replace washed out culvert.	1	1	New License (if deemed navigable)
16.00	Unnamed tributary to Pine Swamp Brook (CV-ST 16.00)	No	Replacement of existing culvert, not presently designed.	1	1	Maintenance
17.37	Pine Swamp Brook #1 (CV-ST 17.37)	No	Replacement of existing culvert, not presently designed.	1	1	Maintenance
17.96	Pine Swamp Brook #1 (CV-ST 17.96)	No	Replacement of existing culvert, not presently designed.			
19.50	Taunton River (Bridge T-01-071)	Lic. 3118 / Oct. 19, 1906	Reconstruction of existing crossing outside existing structure, removal of existing abutments.	1	1	New License or License Amendment
19.70	Taunton River (Bridge T-01-072)	Lic. 3118 / Oct. 19, 1906	Existing piles to be replaced by one mid-stream concrete pier. New abutments to be constructed outside existing structure which would then be removed.	1	1	New License or License Amendment
19.80	Taunton River (Bridge T-01-073)	Lic. 2909 / Nov. 1, 1904	Existing piles to be replaced by one mid-stream concrete pier. New abutments to be constructed outside existing structure which would then be removed.	1	1	New License or License Amendment

Milepost	Waterbody	Presently Licensed	Proposed Alteration	Number of Tracks Existing	Number of Tracks Future	Anticipated Chapter 91 Application
20.00	Mill River (Bridge T-01-074)	Lic. 3118 / Oct. 19, 1906	Reconstruction of existing crossing outside existing structure, removal of existing abutments.	1	1	New License or License Amendment

Taunton River—The Taunton River (Figure 4.18-7) is subject to Chapter 91 because it is navigable and presumably public funds have been expended for flood control either upstream or downstream of the existing rail crossings. The Stoughton line crosses the Taunton River at three locations between Dean Street and Weir Junction. Each of these existing crossings contains a single track on pile-supported steel and timber structures. These bridges include a recently installed private water supply pipe maintained by Aquaria Water, Inc. to supply water to a desalination plant.

The proposed replacement bridges would each support a single track on two-span bridges within the approximate footprint of existing structures and would include a replacement water supply line for the Aquaria desalination plant. The proposed construction at each of these crossings is anticipated to result in a net improvement to navigation because the work would include demolishing and removing timber piles supporting the existing structures. The proposed Taunton River bridges would reduce the vertical clearance between the Taunton River and the underside of the structure. The proposed work could be approved, at DEP discretion, as maintenance or a minor project modification provided the final design is determined by DEP to result in a net improvement to navigation. It is anticipated that these three bridges would require a new license or amendment of the existing license.

Mill River—The Mill River (Figure 4.18-7, Tile 1) is jurisdictional because it is navigable by small boat during at least part of the year. Its path through developed areas of Taunton makes it very likely that public funds have been expended for flood control, triggering Chapter 91 jurisdiction. The existing Mill River crossing is a single span open steel and timber bridge conveying a single track. The proposed replacement bridge would upgrade this crossing, but retain a single track. The preliminary design includes removing existing bridge and abutments resulting in an effective widening of approximately 25 feet, a substantial increase in the space available for wildlife movement, and potentially navigation. Preliminary design shows a small decrease in the clearance beneath the bridge. It is anticipated that the new bridge would require a new license or amendment of the existing license.

Additional Bridge and Culvert Replacements—The Stoughton Line improvements would include the replacement of six culverts and a Bridge over the Cowessett Brook. With the possible exception of the culvert designated CV-ST 11.59, these structures are anticipated to be replaced within the footprint of the existing fill and structures without any substantial structural alteration or substantial change in use as defined in the regulations. Accordingly, these improvements are anticipated to be approved by MassDEP as maintenance activities authorized pursuant to 310 CMR 9.22. The culvert at milepost 11.59 was washed out several years ago and would be replaced by a new bridge over Black Brook. If this section of Black Brook is deemed navigable by MassDEP, this bridge would require a new license.

Coastal Zone Areas

The Stoughton Line is entirely within inland communities and does not include any work within filled tidelands, flowed tidelands or the Massachusetts Coastal Zone.

Whittenton Electric Alternative

In addition to the segments it shares with the Stoughton Electric Alternative, the Whittenton Electric Alternative utilizes an abandoned rail corridor known as the Whittenton Branch to connect the Stoughton Line and the Attleboro Secondary north of Weir Junction in order to avoid Pine Swamp. The Whittenton Branch corridor runs from Raynham Junction in Raynham to Whittenton Junction in Taunton. The Whittenton Branch is a previously developed right-of-way that is no longer in rail service.

The track has been removed from the corridor, but much of the ballast and the bridge over the Mill River remain largely intact.

Chapter 91 Areas

Proposed work includes track construction and ballast and bridge replacement over the Mill River in Taunton. The Mill River in this area is a non-tidal river or stream navigable by canoe and kayak for at least part of the year, and therefore subject to Chapter 91 jurisdiction. There is not presently a license for this crossing.

The existing crossing consists of a four-span concrete pile-supported bridge with stone abutments. The preliminary design for the replacement bridge would provide a two-span structure with one concrete pile, which would result in a reduction in surface area covered by the existing bridge piles, and would result in greater river bottom surface area and bank area. The bridge over the Mill River would be reconstructed with fewer in-water piers than the current bridge, which would enhance navigability. The work is presumed to include removing the existing structures within the river and only a nominal change in the clearance beneath the bridge. This work could be approved as maintenance necessary to restore the serviceability of the existing public transportation structure under 310 CMR 9.22(1) because the work does not include adding a second track.

Coastal Zone Areas

The Whittenton Branch and Attleboro Secondary do not include any work within filled tidelands, flowed tidelands, or within the Massachusetts Coastal Zone.

Stations

Four of the proposed station sites are located on filled tidelands or are within the Massachusetts Coastal Zone: Battleship Cove (Figure 4.18-19 and 4.18-20), Fall River Depot (Figure 4.18-19 and 4.18-21), Freetown (Figure 4.18-15 and 4.18-22), and Whale's Tooth (Figure 4.18-13 and 4.18-23). Table 4.18-8 lists each station and identifies the applicable jurisdiction. The figures show each of the stations within the context of the project and within Chapter 91 and CZM jurisdiction.

Table 4.18-8 Project Elements in Filled Tidelands or Coastal Zone–Station Sites

Station Site	Waterbody	Municipality	Jurisdictional
Battleship Cove	Mount Hope Bay	Fall River	Landlocked Tidelands Coastal Zone
Fall River Depot	Mount Hope Bay	Fall River	Coastal Zone (partial)
Freetown	Taunton River	Freetown	Coastal Zone (partial)
Whale's Tooth	New Bedford Harbor	New Bedford	Landlocked Tidelands Coastal Zone

The following sections describe the anticipated station work within jurisdictional areas and corresponding approvals required.

Battleship Cove Station Site

The Battleship Cove station (Figure 4.18-19 and 4.18-20) would be a new train station constructed along the Fall River Secondary that would serve all Build Alternatives. It would be located on Water Street in Fall River, near the southern terminus of the Fall River Secondary. A conceptual diagram of the station is provided in Figure 4.18-20. This approximately 2.2-acre site is a previously developed parcel within the

Ponta Delgada Plaza. The station would be a platform-only station that would operate during peak hours only. It would serve the downtown area of Fall River and the Battleship Cove tourist area. The station would be designed to encourage walk-in and drop-off/pick-up customers. There is no dedicated parking currently planned at this station.

The Battleship Cove station would be located partially on landlocked tidelands because the station site is located greater than 250 feet from the existing mean high water of the Taunton River and the site was separated by interconnected public ways on January 1, 1984. The construction of the Battleship Cove station would therefore not require a new waterways license.

The station would be located entirely within the coastal zone, while only a portion of the station would be located within the Mount Hope Bay Designated Port Area. The proposed station construction would require a Federal Consistency Certification under the Massachusetts Coastal Zone Management Program because it includes work within the Coastal Zone. The proposed Battleship Cove station is anticipated to be consistent with the regulatory policies.

Fall River Depot Station Site

Fall River Depot station would be a new train (Figure 4.18-19 and 4.18-21) station constructed along the Fall River Secondary for all Build Alternatives. It would be located near the intersection of North Davol Street and Pearce Street, approximately 1 mile north of downtown Fall River. A conceptual diagram of the station is provided in Figure 4.18-21. Part of this approximately 8-acre site was previously developed as an historic train station. The new station is envisioned to be a multi-modal transportation center with new mixed-use development and parking facilities. The station would serve walk-in, bike-in, and drive-in customers.

Fall River Depot station would not be located within filled tidelands and would not be subject to Chapter 91. At the Fall River Depot Station site, Davol Street is the first major transportation infrastructure adjacent to the coast. As a result, the first 100 feet of the site’s frontage on Davol Street are located within the coastal zone associated with the Taunton River. The majority of the station site is located landward of the coastal zone boundary.

The proposed station construction would require a Federal Consistency Certification under the Coastal Zone Management Program because it includes work within the Massachusetts Coastal Zone. The proposed station construction is anticipated to be consistent with the regulatory policies.

Freetown Station Site

Freetown station would be a new train (Figure 4.18-15) station constructed to serve the Fall River Secondary for all Build Alternatives. It would be located along South Main Street in Freetown, at a site currently occupied by a self-storage business. A conceptual diagram of the station is provided in Figure 4.18-22. The approximately 18-acre site is near the Fall River Executive Park and the River Front Park. The station would serve drive-in customers and customers shuttled between the station and these nearby industrial parks.

Freetown station would not be located within filled tidelands and therefore would not be subject to Chapter 91. At the Freetown station site, South Main Street is the first major transportation infrastructure adjacent to the coast. As a result, the first 100 feet of the site’s frontage are located

within the coastal zone associated with the Taunton River (the entrance driveway). The majority of the station site is located landward of the coastal zone boundary.

The proposed driveway station construction would require a Federal Consistency Certification under the Coastal Zone Management Program because it includes work within the Massachusetts Coastal Zone. The proposed station construction is anticipated to be consistent with the regulatory policies.

Whale's Tooth Station Site

Whale's Tooth station would be a new train (Figure 4.18-13) station constructed in New Bedford along the New Bedford Main line and would serve all Build Alternatives. It would be located near the intersection of Acushnet Avenue and Hillman Street, near the southern terminus of the New Bedford Main line. A conceptual diagram of the station is provided in Figure 4.18-23. The City of New Bedford has constructed a parking lot on the approximately 14-acre site in anticipation of the South Coast Rail project. The station would include intermodal connections, potentially linking to ferry services. The station would serve walk-in, bike-in and drive-in customers.

The majority of the Whale's Tooth station would be located on landlocked filled tidelands because the station site was entirely separated from the existing mean high water mark of New Bedford Harbor by interconnected public ways on January 1, 1984, and is at least 250 feet landward of the existing mean high water mark. Accordingly, the station would not require a Waterways license. However, the station would require a Public Benefit Determination (see Section 4.18.5).

The station would be located entirely within the Coastal Zone associated with New Bedford Inner Harbor, but outside the New Bedford/Fairhaven DPA. The proposed station construction would require a Federal Consistency Certification under the Coastal Zone Management Program because it includes work within the Massachusetts Coastal Zone. The proposed station construction is anticipated to be consistent with the regulatory policies.

Layover Facilities

Two layover facilities are planned for the Southern Triangle: one near the southern end of the Fall River Secondary and another near the southern end of the New Bedford Main Line. The two proposed sites, listed below in Table 4.18-9, require evaluation for compliance with Chapter 91 and Coastal Zone management requirements. Coastal zone consistency and impacts to filled tidelands are described below for the Wamsutta, Weaver's Cove East layover sites, as applicable.

Table 4.18-9 Project Elements in Filled Tidelands–Layover Sites

Facility Name	Waterbody	Municipality	Jurisdictional
Wamsutta	New Bedford Harbor	New Bedford	Landlocked Tidelands Coastal Zone
Weaver's Cove East	Taunton River	Fall River	Filled Tidelands Coastal Zone

The following sections describe the location, jurisdiction and proposed work required for these layover facilities.

Fall River –Weaver's Cove East Layover Facility Site

The Weaver's Cove East layover facility (Figure 4.18-16) would be constructed along the Fall River Secondary and would serve all Build Alternatives. It would be located off of Main Street between the

existing Fall River Secondary freight line and the Taunton River, approximately 2.5 miles from the southern terminus of the Fall River Secondary. The Weaver's Cove East Layover Facility is subject to licensing and therefore required to comply with 310 CMR 9.37(2). It would be located approximately 20 feet above the current shoreline and would not be expected to experience inundation even under the highest predicted sea level rise of 6.6 feet by 2100.

Consultation with DEP Waterways' staff indicated that the Department considers that the Weaver's Cove East layover facility to be located within filled tidelands. The jurisdictional boundary is based on the shoreline shown on two historic maps provided by the DEP prepared in 1865 and 1874 (Figure 4.18-24 and 4.18-25). Both of these maps postdate the construction of the railroad. It is likely that the railroad impounded water in the vicinity of the proposed layover facility and this impoundment is represented on these historic maps. As such, the construction of the proposed layover facility would require a new Chapter 91 license. The Waterways Regulations are designed to protect and promote the public's interest in tidelands through the inclusion of provisions to conserve the capacity for water-dependent uses. The use of the site for layover needs is classified by DEP as a nonwater-dependent Infrastructure Facility (310 CMR 9.55). This classification may waive some of the above-referenced provisions, as long as feasible mitigation or compensation measures are provided such as the protection of maritime commerce or recreation and associated public access, reduction of flood and erosion-related hazards on lands subject to the 100-year flood or projected sea level rise, and the attainment of water quality goals.

The layover facility would be located entirely within the coastal zone associated with the Taunton River but outside the Mount Hope Bay DPA. Accordingly, the proposed layover facility would require a Federal Consistency Certification under the MCZMP. The proposed facility is anticipated to be consistent with the regulatory policies of the MCZMP.

New Bedford –Wamsutta Layover Facility Site

The Wamsutta layover facility (Figure 4.18-12) would be constructed along the New Bedford Main Line and would serve all Build Alternatives. It would be located near the intersection of Wamsutta Street and Herman Melville Boulevard, near the southern terminus of the New Bedford Main line. This location is just north of the Whale's Tooth Station site described above. The site is currently an active CSX rail yard used for freight. The existing and proposed rail yard is located on top of a capped hazardous waste facility.

The proposed Wamsutta layover facility would be located in landlocked tidelands and would be exempt from licensing under 310 CMR 9.04(2). The construction of the Wamsutta layover facility would require a Public Benefit Determination under 301 CMR 13.00.

The layover facility would be located entirely within the coastal zone associated with New Bedford Inner Harbor but is not within the new Bedford/Fairhaven DPA. The construction would require a Federal Consistency Certification under the Massachusetts Coastal Zone Management Program. The proposed facility is anticipated to be consistent with the regulatory policies of the MCZMP.

4.18.5 Public Benefit Determination

Portions of the South Coast Rail project are subject to the requirements of Chapter 168 of the Acts of 2007 because they are located on landlocked filled tidelands. The identification of landlocked tidelands is described above and is based on cartographic data published by MassGIS on behalf of DEP and OCZM.

The South Coast Rail project exceeds EIR review thresholds as defined in 301 CMR 11.03 and requires a Public Benefit Determination in accordance with the regulations at 301 CMR 13.00.[1] The Act requires projects subject to MEPA to consider a project's potential impacts on groundwater and in cases where projects are located in areas of known low groundwater include measures to avoid, minimize or mitigate potential impacts.

When making a Public Benefit Determination, the Secretary is required to consider the:

- Purpose and effect of the development;
- Impact on abutters and the surrounding community;
- Enhancement of the property;
- Benefits to the public trust rights in tidelands or other associated rights;
- Community activities on the development site;
- Environmental protection and preservation;
- Public health and safety;
- General welfare; and
- Protection of Groundwater.

The Secretary is also instructed by 301 CMR 13.00 to consider the differences between tidelands, landlocked tidelands, and great ponds when assessing the public benefit and shall consider the practical impact of the public benefit on development.

The South Coast Rail project elements that are located on filled tidelands, located at least 250 feet landward of existing flowed tidelands, and completely separated from flowed tidelands by one or more intervening roads are:

- Battleship Cove Station, Fall River;
- Whale's Tooth Station, New Bedford; and
- Wamsutta Layover Facility, New Bedford.

The following sections describe how each of the these stations and the layover facility provide appropriate public benefits and are adequately protective of the public's inherent rights in present and former waterways, held in trust by the Commonwealth for the benefit of the public.

MassDOT's purpose for the South Coast Rail project is "to more fully meet the existing and future demand for public transportation between Fall River/New Bedford and Boston, and to enhance regional mobility, while supporting smart growth planning and development strategies in affected communities."

[1] The public benefit determination discussed in this section is a state requirement unrelated to the U.S. Army Corps of Engineers public interest review as part of Clean Water Act Section 404 permitting.

Battleship Cove Station

The Battleship Cove Station (Figure 4.18-19 and 4.18-20) would be a new station constructed at the southern terminus of the Fall River Secondary, on Water Street in Fall River. This site is adjacent to the previously developed Ponta Delgada Plaza. The station would be a platform-only station that would operate during peak hours. It would serve downtown Fall River and the Battleship Cove tourist area. The station would be designed to encourage walk-in and drop-off/pick-up customers. Dedicated parking is not planned for this station.

The Battleship Cove Station site is approximately 825 feet from the nearest flowed tidelands of the Taunton River. A portion of the site is located on filled tidelands entirely separated from the flowed tidelands by Water Street.

MassDOT is currently developing plans for modified access ramps to Route 79 which would cross the proposed station. These ramps, if constructed, would change adjacent land uses and traffic patterns, and would change the visual environment in the vicinity of the station.

Purpose and Effect of the Development

The purpose of the Battleship Cove Station is to provide commuter rail access to the downtown and Battleship Cove areas of Fall River, providing new transportation access to the regional MBTA services. The station is intended to operate during peak morning and evening hours.

The effects of the development would be the creation of a new public transportation facility providing regional commuter rail service to downtown Fall River and the Battleship Cove area where none presently exists; and construction of approximately 10,000 square feet of platform within an area of filled tidelands.

Impact on Abutters and Community

The Battleship Cove Station is expected to result in a net benefit to abutting properties and the Fall River community. Potential adverse impacts to abutters are expected to be minimal because the adjacent private uses are light commercial/ industrial and warehousing. The proposed station is not expected to interfere with these uses and would result in small net benefit by revitalizing the existing rail infrastructure adjacent to the site.

Potential impacts to the community are expected to be beneficial, resulting from a new transportation link to the regional MBTA system. There would be no impact on the existing park.

Enhancement of the Property

The proposed Battleship Cove Station would enhance the site by rehabilitating the existing rail infrastructure along this section of the Fall River Secondary and activating the property for public transportation use.

Benefits to the Public Trust Rights in Tidelands or Other Associated Rights

The Battleship Cove Station would provide net benefit to the public trust rights in filled tidelands at the site by providing new public access and public transportation uses to the Fall River Secondary and adjacent land. The traditional public trust rights to tidelands include fishing, fowling, and navigation.

While these activities are not possible on the site due to its location approximately 825 feet from the nearest flowed tidelands, the logical extension of such rights in filled tidelands protected by Chapter 91 include the public's rights to pedestrian access and other lawful purposes.

The proposed station and associated public transportation uses would meet these goals. While much of the site contains an open grassy landscaped area adjacent to the Ponta Delgada Monument and plaza and is open to the public, access would not be affected by the station.

Community Activities on the Site

The Battleship Cove Station would increase community activities at the site by providing new access to the regional rail transportation network. The MBTA estimates that approximately 240 daily passengers would use the station.

Environmental Protection/Preservation

The Battleship Cove Station construction would meet all local, state and federal environmental protection requirements and comply with all applicable regulations, as identified in the extensive public review process.

Public Health and Safety

The South Coast Rail project would promote public health and safety through a site design that provides a safe and universally accessible facility for public use. Providing passenger rail service to the Battleship Cove Station and adjacent downtown Fall River area would result in net benefits to public health and safety resulting from a reduction in single passenger vehicle trips, air pollution and regional traffic.

General Welfare

The Battleship Cove Station would promote the general welfare by providing area residents with new public access to the existing regional transportation system. MassDOT would use public funds to provide direct and tangible benefits to the residents and visitors to the Battleship Cove area. The station has been designed to promote use by local residents. The potential for traffic impacts has been mitigated by limiting the number of parking spaces at the station site to the required handicapped-accessible spaces only, and by promoting pick-up/drop-off and local bus connections.

Protection of Groundwater

The Battleship Cove Station site is not within an area of known low groundwater, and is not anticipated to have any adverse impacts to the existing groundwater conditions. The station would be a platform constructed essentially at-grade. No basement, extensive excavation, or groundwater cut-off wall are proposed during construction and no short- or long-term impacts to groundwater are anticipated.

Whale's Tooth Station

Whale's Tooth Station would be a new train station constructed in New Bedford (Figure 4.18-13 and 4.18-23). It would be located near the intersection of Acushnet Avenue and Hillman Street, near the southern terminus of the New Bedford Main Line. The City of New Bedford has constructed a parking lot on the approximately 14-acre site in anticipation of the South Coast Rail project. The station would

include intermodal connections, potentially linking to ferry services. The station would serve walk-in, bike-in and drive-in customers.

The majority of the Whale's Tooth Station would be located on landlocked filled tidelands because the station site is entirely separated from the mean high water mark of New Bedford Harbor by interconnected public ways and is at least 250 feet landward of the mean high water mark. The station would require a Public Benefit Determination, but not a Waterways license. The following sections describe the public benefits of the proposed Whale's Tooth Station.

Purpose and Effect of the Development

The purpose of the Whale's Tooth Station is to provide new passenger rail or bus access to the New Bedford downtown waterfront area, improving access to the MBTA and regional public transportation network. The station would be adjacent to an existing City of New Bedford parking lot and would be accessible to passengers walking, biking, or driving to the station.

The effects of the development would be the creation of a new public transportation facility providing commuter rail service to the downtown New Bedford area, and activation of filled tidelands for public use for construction of the proposed station and vehicle circulation areas.

Impact on Abutters and Community

The Whale's Tooth Station is expected to result in minimal adverse impacts to abutters and a net benefit to the New Bedford community. Adverse impacts to abutters are expected to be minimal because the adjacent properties consist primarily of Route 18 (a six-lane divided highway) and industrial/trucking properties to the west and south, vacant land and industrial properties to the east, and the Greater New Bedford Career Center to the north.

None of these existing uses are likely to be disrupted either by construction or operation of the proposed station. The Greater New Bedford Career Center users would benefit from improved access to the regional transportation network by providing their clientele with improved access to career opportunities along the proposed passenger rail corridor.

The New Bedford community at large would also benefit from the proposed station by gaining short-term construction related jobs and long-term improved access to the regional transportation network. No short-term adverse impacts to the community are expected.

Enhancement of the Property

The Whale's Tooth Station would enhance the property by providing new public transportation infrastructure adjacent to an existing paved parking lot.

Benefits to the Public Trust Rights in Tidelands or Other Associated Rights

The Whale's Tooth Station would provide a net benefit to the public trust rights in filled tidelands at the site by providing new access to the planned passenger rail network. The City of New Bedford has constructed a new parking lot on the site in anticipation of the project. The proposed station would enhance the public's use of the landlocked tidelands by increasing utilization of the site and providing access to additional regional transportation options.

Community Activities on the Site

The Whale's Tooth Station would increase community activities at the site by increasing utilization of the existing 14-acre paved parking facilities at the site.

Environmental Protection/Preservation

The Whale's Tooth Station construction would meet all local, state and federal environmental protection requirements and comply with all applicable regulations, as identified in the extensive public review process.

Public Health and Safety

The South Coast Rail project would promote public health and safety through a site design that provides a safe and universally accessible facility for public use. Providing passenger rail service to the site and the downtown New Bedford area would result in net benefits to public health and safety resulting from a reduction in single passenger vehicle trips, air pollution, and regional traffic.

General Welfare

The Whale's Tooth Station would promote the general welfare by providing area residents with new public access to the existing regional transportation system. MassDOT would use public funds to provide direct and tangible benefits to the residents and visitors to New Bedford. The station's proximity to Route 18, a six lane divided highway, and existing local bus services would take advantage of the existing road network reducing potential adverse transportation impacts that could result from the South Coast Rail project. The 14-acre surface parking lot constructed by the City of New Bedford at the site would minimize potential impacts to parking in the vicinity of the site.

Protection of Groundwater

The Whale's Tooth Station site is not within an area of known low groundwater, and would not be anticipated to have any adverse impacts to the existing groundwater conditions. The station would be a single platform constructed at grade. No basement, extensive excavation or groundwater cut-off walls are proposed during construction and no short- or long-term impacts to groundwater are anticipated.

Wamsutta Layover Facility

The Wamsutta Layover Facility (Figure 4.18-12 and 4.18-13) would be constructed along the New Bedford Main Line. It would be located near the intersection of Wamsutta Street and Herman Melville Boulevard, near the southern terminus of the New Bedford Main Line. This location is just north of the Whale's Tooth Station site described above. A portion of the site is currently an active CSX rail yard used for freight. The existing and proposed rail yard is located on top of a capped hazardous waste landfill.

The Wamsutta Layover Facility would be entirely within landlocked tidelands because the site is entirely separated from the water sheet of New Bedford Harbor by Herman Melville Boulevard (a public way in existence on January 1, 1984) and it is located at least 250 feet from the existing mean high water mark.

The following sections describe the public benefits resulting from the construction of that portion of the proposed Wamsutta Layover Facility within landlocked tidelands.

Purpose and Effect of the Development

The purpose of the Wamsutta Layover Facility is to provide an overnight storage site for equipment needed for the early morning trains departing New Bedford for Boston. In most cases, these trains would have completed one of the last southbound runs of the prior day. Making use of a terminal layover facility avoids the need to run empty equipment to Boston for overnight storage and then back to New Bedford for the first northbound train. This important operation detail would reduce fuel consumption, operation and maintenance costs, and potential environmental impacts to air quality and noise associated with extra late-night and early morning trains.

Potential impacts to the community are expected to be minimal because the proposed site is currently an active CSX freight rail yard located along the waterfront in an area dominated by commercial, industrial and warehouse properties.

Impact on Abutters and Community

The Wamsutta Layover Facility is expected to have minimal adverse impacts to abutters, a net benefit to the New Bedford community and a substantial benefit to abutters to the New Bedford Main Line. Adverse impacts to abutters are expected to be minimal because the site is currently used as an active freight rail yard and construction would be limited to:

- Reconstructing the existing rail infrastructure;
- Installing electric utilities to serve the facility and a drainage system designed to collect and treat stormwater runoff prior to discharge from the site;
- Constructing a small operations building with crew facilities and a small number of parking spaces to support train crews and operations staff.

The Wamsutta Layover Facility would result in a net benefit to each community adjacent to the New Bedford Main Line and the Stoughton Line because the facility would prevent the need to shuttle empty passenger trains north in the evening and south before the first scheduled northbound train, reducing the potential for air quality and noise impacts on these communities.

Enhancement of the Property

The proposed Wamsutta Layover Facility would marginally enhance the property by replacing one rail use with another.

Benefits to the Public Trust Rights in Tidelands or Other Associated Rights

The Wamsutta Layover Facility would improve the capacity of the site to protect the public trust rights in filled tidelands by converting a private freight rail yard to a public transportation facility. As a matter of public safety, the existing use precludes public access for any purpose. While the proposed facility would also prohibit public access to these filled tidelands, the change in use would benefit trust rights in these lands by providing a vital transportation infrastructure facility.

Community Activities on the Site

The Wamsutta Layover Facility is not expected to increase community activities at the site because all public access would continue to be prohibited as a matter of public safety.

Environmental Protection/Preservation

The Wamsutta Layover Facility construction and operation would meet all local, state and federal environmental protection requirements and comply with all applicable regulations, as identified in the extensive public review process.

Public Health and Safety

The South Coast Rail project would promote public health and safety through implementing a site design that provides a safe and universally accessible facility for operator use while restricting public access. The proposed facility would continue to serve as a cap for the soils containing oil and hazardous materials present at the site. The site would be fenced and lighted to further protect public health and safety. Additionally, siting an overnight layover facility at the New Bedford Main Line terminus would eliminate the need to shuttle empty trains north following the last run of the evening and back to New Bedford for the first morning commute, reducing the potential for air quality and noise impacts.

General Welfare

The Wamsutta Layover Facility would promote the general welfare by activating the filled tidelands at the site for a public purpose, reducing extra train trips which would otherwise be required, resulting in fewer potential environmental impacts and substantial saving in fuel and operations and maintenance costs for the life on the project.

Protection of Groundwater

The proposed Wamsutta Layover Facility is not within an area of known low groundwater, and is not expected to have any discernible impact on groundwater at the project site because the site is a capped hazardous materials site and is designed to prevent infiltration of surface runoff to groundwater.

Public Benefits Determination Summary

MassDOT's project purpose is "to more fully meet the existing and future demand for public transportation between Fall River/New Bedford and Boston, and to enhance regional mobility, while supporting smart growth planning and development strategies in affected communities." The project would have a substantial public benefit by improving transportation to the under-served South Coast communities.

The South Coast Rail project elements proposed within landlocked tidelands have been sited and preliminarily designed to protect the public interests in tidelands and result in public benefits as required by Chapter 168 of the Acts of 2007 and in accordance with the regulations at 301 CMR 13.00. The project would result in substantial net benefits to the public interest in filled tidelands by revitalizing and expanding public infrastructure in a manner which meets all applicable state and federal environmental protection standards while minimizing potential impacts to abutters to these stations and layover facility and the community.

4.18.6 Coastal Zone Management

The Massachusetts Coastal Zone Management Plan and regulations implement the federal Coastal Zone Management Act of 1972, as amended (16 U.S.C. 1451 et seq.). The Coastal Zone Management Act established federal statutory authority to the management of the nation's coastal resources balancing economic development with environmental conservation. The Massachusetts Coastal Zone Management Act (MGL Chapter 21A, Sections 2 and 4A) established local authority to implement the Massachusetts Coastal Zone Management Plan (CZMP) through regulations at 301 CMR 20.00 through 301 CMR 25.00. The following regulations are most pertinent to the South Coast Rail project:

- 301 CMR 21.00 requires a federal consistency certification issued by the Office of Coastal Zone Management for projects in the coastal zone deemed likely to affect the coastal zone and require a federal action.

- 301 CMR 23.00 establishes state procedures for the preparation of Municipal Harbor Plans. Approved plans provide municipalities a mechanism for modifying certain requirements of Chapter 91 Licensing.

- 301 CMR 25.00 establishes state authority to delineate Designated Port Areas within the coastal zone to protect the unique capacity of developed ports and port infrastructure to support water-dependent industrial activities.

These regulations, in concert with the Waterways Regulations (310 CMR 9.00), create a regulatory framework for planning, licensing and implementing projects in the Massachusetts Coastal Zone. The South Coast Rail project includes track, stations and layover facilities within the Massachusetts Coastal Zone and would require compliance with each of these regulations.

The Massachusetts Coastal Zone Management regulations at 310 CMR 21.98 establish twenty program policies and nine management principles that projects subject to federal consistency certification must comply with. The following sections provide a summary of each of the twenty-five program policies and three management principles established by 301 CMR 21.98 and describes how the project is consistent with each applicable policy or management principle.

The program’s twenty-eight policies and principles are divided into the following 9 categories:

- water quality;

- habitat;

- protected areas;

- coastal hazards;

- port and harbor infrastructure;

- public access;

- energy;

- ocean resources; and
- growth management.

This section lists each policy and management principle as contained in the regulations at 301 CMR 21.00 and demonstrates that the project can be designed and constructed consistent with them.

4.18.6.1 Water Quality

This section addresses the South Coast Rail project's compliance with water quality standards and identifies pollution prevention and low impact development (LID) measures at proposed station sites and layover facilities.

Compliance with state water quality standards and policies is a requirement for federal consistency under the CZMP and the regulations at 301 CMR 21.98. This regulation establishes the CZMP's programmatic policies and management principles which form the basis for federal consistency.

Water Quality Policy #1

Ensure that point-source discharges in or affecting the coastal zone are consistent with federally approved state effluent limitations and water quality standards.

Water Quality Policy #2

Ensure that nonpoint pollution controls promote the attainment of state surface water quality standards in the coastal zone.

Chapter 4.17, *Water Resources*, provides a comprehensive review of the project's compliance with applicable state and federal water quality standards regarding point-source, nonpoint-source, and subsurface discharges at proposed stations and layover facilities. The South Coast Rail project has been designed to meet these environmental protection requirements through compliance with all applicable federal and state regulations governing sources or air and water pollution and wetland protection.

The South Coast Rail project's compliance with the Wetlands Protection Act stormwater regulations are described in Chapter 4.17, *Water Resources*. Compliance with the NPDES Construction General Permit would be achieved through the preparation and filing of a NPDES Notice of Intent and a Stormwater Pollution Prevention Plan (SWPPP) for each station or layover facility site. Compliance with operational stormwater requirements would be achieved through the use of LID measures designed to control the volume, rate, and quality of stormwater runoff discharged from each station or layover facility. LID measures planned for the proposed stations and layover facilities are described in detail in Chapter 4.17, *Water Resources*. The design and construction of the project will be subject to numerous levels of local, state and federal review. This multi-layer permitting process will help ensure that the project is constructed and operated in accordance with these standards.

Water Quality Policy #3

Ensure that activities in or affecting the coastal zone conform to applicable state and federal requirements governing subsurface waste discharges.

Subsurface Waste Discharges

Layover facilities would have limited water use for sanitary facilities. Effluent from these uses would be discharged to municipal sanitary treatment facilities. The South Coast Rail project does not involve subsurface waste discharges.

Air Pollution

The South Coast Rail project would result in a net reduction in air pollution and a net benefit to regional air quality as described in detail in Chapter 4.9, *Air Quality*. The South Coast Rail project is not anticipated to require any new local, state, or federal permit related to air pollution.

Water Pollution

The South Coast Rail project would meet all applicable local, state, and federal requirements regarding potential water pollution and MassDOT would obtain all needed permits under these regulations as described in Chapter 4.17. No point source discharges are proposed. All storm water collected at stations and layover facilities would be treated in accordance with the Massachusetts Stormwater Regulations and, for layover facilities, in accordance with applicable NPDES discharge requirements.

Wetland Protection

The South Coast Rail project would protect state and federally regulated wetlands by adherence to all applicable regulations. The project has been designed to avoid, minimize, and mitigate wetland impacts to the greatest extent practicable and is anticipated to receive permits under the Massachusetts Wetlands Protection Act, Section 401 of the Clean Water Act (Water Quality Certificate) and Section 404 of the federal Clean Water Act. The project would require a Variance under the Wetlands Protection Act pursuant to 310 CMR 10.05(10) subject to approval by the MassDEP Commissioner. The Commissioner may waive certain regulations when mitigating measures are proposed that would allow the project to be conditioned so as to contribute to the public interests in wetlands.

Chapter 4.16, *Wetlands*, provides a complete description of the anticipated wetland impacts and proposed mitigation measures.

4.18.6.2 Habitat

Habitat Policy #1

Protect coastal resource areas including salt marshes, shellfish beds, dunes, beaches, barrier beaches, salt ponds, eelgrass beds, and fresh water wetlands for their important role as natural habitats.

The proposed project would not alter any coastal resource area including salt marshes, shellfish beds, dunes, beaches, barrier beaches, salt ponds or eelgrass beds. In addition, no impacts to freshwater wetlands are proposed within the Coastal Zone.

Habitat Policy #2

Restore degraded or former wetland resources in coastal areas and ensure that activities in coastal areas do not further wetland degradation but instead take advantage of opportunities to engage in wetland restoration.

The Build Alternatives would be designed to comply with this policy. A complete description of the alternatives' potential impacts to wetland resources is presented in Chapter 4.16, *Wetlands*.

4.18.6.3 Protected Areas

Protected Areas Policy #1

Preserve, restore, and enhance complexes of coastal resources of regional or statewide significance through the Areas of Critical Environmental Concern program.

None of the Build Alternatives include any work within a coastal ACEC nor would it affect natural coastal resources. ACECs are discussed in Chapter 4.10, *Protected Open Space and Areas of Critical Environmental Concern*.

Protected Areas Policy #2

Protect state and locally designated scenic rivers and state classified scenic rivers in the coastal zone.

The Taunton River has been designated as a "Partnership Wild and Scenic River." The proposed work within the Taunton River would be designed to the extent practicable with the 2005 Taunton River Stewardship Plan consistent with the National Park Service requirement of the Wild and Scenic Rivers Act.

Protected Areas Policy #3

Ensure that proposed developments in or near designated or registered historic districts or sites respect the preservation intent of the designation and that potential adverse effects are minimized.

Each Build Alternative would be designed to comply with applicable historic preservation standards and include efforts to avoid, minimize and mitigate potential impacts to historic resources. Chapter 4.8, *Cultural Resources*, provides a complete description of the potential impacts to historic resources.

4.18.6.4 Coastal Hazards

Coastal Hazard Policy #1

Preserve, protect, restore, and enhance the beneficial functions of storm damage prevention and flood control provided by natural coastal landforms, such as dunes, beaches, barrier beaches, coastal banks, Land Subject to Coastal Storm Flowage, salt marshes, and land under the ocean.

This policy is not applicable to any of the Build Alternatives because they do not impact coastal landforms.

Coastal Hazard Policy #2

Ensure construction in waterbodies and contiguous land areas will minimize interference with water circulation and sediment transport. Approve permits for flood or erosion control projects only when it has been determined that there will be no significant adverse effects on the project site or adjacent or downcoast areas.

None of the Build Alternatives includes work within coastal waterbodies and none would interfere with water circulation or sediment transport in any coastal waterbody.

Coastal Hazard Policy #3

Ensure that state and federally funded public works projects proposed for location within the coastal zone will:

- not exacerbate existing hazards or damage natural buffers or other natural resources;
- be reasonably safe from flood and erosion related damage;
- not promote growth and development in hazard-prone or buffer areas, especially in Velocity zones and ACECs; and
- not be used on Coastal Barrier Resource Units for new or substantial reconstruction of structures in a manner inconsistent with the Coastal Barrier Resource/Improvement Acts.

The South Coast Rail project would not significantly alter natural buffers in the Coastal Zone and would not promote development in hazard-prone or buffer areas. A small portion of the Weaver's Cove Layover Facility site is within the FEMA flood zone. Project elements proposed for this area are reasonably safe from flood and erosion-related damage.

Coastal Hazard Policy #4

Prioritize public funds for acquisition of hazardous coastal areas for conservation or recreation use, and relocation of structures out of coastal high hazard areas, giving due consideration to the effects of coastal hazards at the location to the use and manageability of the area.

The policy is not applicable to the alternatives.

4.18.6.5 Port and Harbor Infrastructure

The Municipal Harbor Planning process is voluntary, established by the regulations at 301 CMR 23.00 under which municipalities may implement local planning goals for their waterfronts. Harbor plans are prepared in coordination between local officials, the OCZM, DEP, and other state agencies either controlling real property or planning state actions in the harbor planning area.

An approved Municipal Harbor Plan (MHP) is intended to guide state agency actions related to waterfront development, permitting and planning and provides a formal mechanism for local input to the Chapter 91 licensing process. Approved plans may substitute numerical provisions regarding building height, setbacks, open space, and ground floor uses within Commonwealth tidelands.

The South Coast Rail project includes construction activities and changes in use within the geographic planning area for two MHPs:

- New Bedford/Fairhaven Municipal Harbor Plan, and
- Fall River Municipal Harbor and Downtown Economic Development Plan.

The following sections describe the South Coast Rail project's consistency with these MHPs. Subsequent sections demonstrate compliance with the policies contained in Ports and Harbors.

New Bedford/Fairhaven Municipal Harbor Plan

The New Bedford/Fairhaven MHP was prepared through a collaborative effort by the Cities of New Bedford and Fairhaven, the OCZM, MassDEP, and the Seaport Advisory Council. The New Bedford/Fairhaven MHP was approved by the Secretary of Energy and Environmental Affairs on June 14, 2012.

The harbor planning area, shown on Figures 4.18-11 and 4.18-12, includes the existing track extending south from Coggeshall Street (north of the I-195 interchange) to the southern terminus of the New Bedford Main Line near the Whale's Tooth Station. The harbor planning area extends approximately 2,000 to 3,000 feet landward from the watersheet of New Bedford Harbor.

This planning area includes the proposed sites for the Wamsutta Layover Facility and the Whale's Tooth Station. To the extent that these facilities are subject to licensing under Chapter 91, the proposed project elements must be consistent with the approved harbor plan to comply with the provisions of 310 CMR 9.34

Pursuant to 301 CMR 23.05(3), MassDOT has been an active participant in the development of the New Bedford/Fairhaven MHP as it relates to the South Coast Rail project. In February 2010, MassDOT provided written comments to the OCZM that the plan was consistent with their proposed plans and activities.

One of the major initiatives supported by the New Bedford/Fairhaven MHP is: "Improved Transportation Connections including …establishing a passenger rail link to Boston…"

The plan's specific recommendations state that: "The restoration of passenger and freight rail service to the North Harbor creates the landside conditions essential for successful development of expanded port terminal facilities in this area."

The plan recognizes the importance of restoring rail service as a critical component of transportation and industrial infrastructure in the port of New Bedford. The South Coast Rail project supports the New Bedford/Fairhaven Green Ports Initiative and provides intermodal connection to the ferries serving Martha's Vineyard, Cuttyhunk, Woods Hole, and Nantucket via a locally-operated shuttle bus system.

The New Bedford/Fairhaven MHP identifies the combined Whale's Tooth Station as a suitable location to support commuter rail, local and regional bus service, taxis, and waterfront trolley service, and potentially accommodate future rail and pedestrian links to a water terminal.

The New Bedford/Fairhaven MHP concludes by stating that: "The addition of public passenger transport rail enhancements to the existing rail infrastructure at the CSX rail facility represents a significant potential expansion to the economy of the entire region"

In summary, the New Bedford/Fairhaven MHP was developed in collaboration with state agency stakeholders and was reviewed by MassDOT prior to submittal. The plan and the Secretary's Approval Decision recognize the importance of the planned rail improvements to the success of the harbor planning area, the City of New Bedford, and the region.

Fall River Municipal Harbor and Downtown Economic Development Plan

In October 2002, the City of Fall River completed an Economic Development Plan in consultation with a diverse group of regional stakeholders including the OCZM and MassDEP. The Economic Development Plan included the following Statement of Purpose: "The purpose of the Fall River Harbor and Downtown Economic Development Plan is to increase the economic diversity of the community through the expanded use and revitalization of the harbor, the harborfront, and nearby areas within the downtown. The Plan seeks to establish a clear vision for these areas and to create a pragmatic strategy for accomplishing that vision."

The plan was prepared with the goal of obtaining approval by the Massachusetts Secretary of Energy and Environmental Affairs under the provisions of Municipal Harbor Plan Approval (301 CMR 23.00). While the Economic Development Plan was submitted to the Secretary for approval, it was not approved pending further revisions. Therefore, the Economic Development Plan does not meet the regulatory criteria for approved harbor plans and does not serve as formal regulatory guidance for the licensing process.

The South Coast Rail project has been planned and preliminarily designed in a manner consistent with the Fall River Harbor and Downtown Economic Development Plan in terms of supporting water dependent uses and improving public access to the Fall River waterfront while avoiding non-water dependent uses in the DPA or filled tidelands subject to licensing.

The South Coast Rail project includes the reconstruction of track, ballast, water-dependent infrastructure facility crossings and the construction of one new passenger station at Battleship Cove. The station site is well located to meet an overriding vision of the Harbor and Economic Development Plan for the downtown waterfront: "The vision for the waterfront would achieve a higher quality of life by expanding active uses, becoming more accessible to all residents and attracting an increasing number of visitors."

Additionally, the Battleship Cove Station site furthers two specific goals of the harbor plan:

- "The harborfront and the downtown should be enhanced as a visitor destination," and
- "The transportation infrastructure should be focus of appropriate reinvestment that better connects people to their destinations, and supports comprehensive economic goals."

The Battleship Cove Station is centrally located between the densely populated residential neighborhood bounded by Broadway, South Main Street and Kennedy Park. It would be adjacent to the City Gates at Ponta Delgada Park and adjacent to the Water Street/Ferry Street corridor connecting Heritage State Park and Kennedy Park.

The City of Fall River, with assistance from MassDOT, is presently exploring ways to improve pedestrian connections along Fall River's urban waterfront. Critical links being explored at this time include new pedestrian connections between Broadway and Canal Streets to the Battleship Cove Station site and improvements along Water and Ferry Streets. These connections, considered in the context of the planned station, would significantly improve pedestrian access to the waterfront. The Battleship Cove Station would provide new access to the regional transportation network encouraging residents to use these new connections and deliver new visitors to Fall River.

4.18.6.6 Consistency with Designated Port Areas

Massachusetts regulations at 301 CMR 25.00, promulgated pursuant to MGL Chapter 21A, Sections 2 and 4A, established state authority to delineate DPAs within developed industrial waterfronts. The purpose of delineating DPAs is to identify geographic areas of particular state, regional and national significance with respect to the promotion of commercial fishing, shipping and other vessel-related activities associated with waterborne commerce, and of manufacturing, processing, and production activities. Eleven DPAs were subsequently identified by the OCZM and approved by the Secretary of Energy and Environmental Affairs.

The South Coast Rail project includes work in the Mount Hope Bay in Fall River (Figure 4.18-16) and New Bedford/Fairhaven DPAs (Figures 4.18-11 and 4.18-12). These figures show the location of the proposed stations and layover facilities and the regulatory boundaries of these DPAs. The only South Coast Rail project elements within these DPAs are the existing track segments listed in Table 4.18-10.

Table 4.18-10 Project Elements in Designated Port Areas

Designated Port Area	Project Element	Location
Mount Hope Bay	2,000 ± LF of track	South of Weaver's Cove
	500 + LF of track	North of Battleship Cove Station
New Bedford/Fairhaven	500 + LF of track	South of Wamsutta Layover Facility

The South Coast Rail project has been designed to avoid construction of stations and layover facilities within the Mount Hope Bay (Fall River) and New Bedford/ Fairhaven DPAs. The only project-related work proposed within these DPAs is the reconstruction of existing track, ballast, and associated infrastructure.

The CZM regulations include the following port and harbor infrastructure policies and management principles related to projects located in the Massachusetts Coastal Zone:

Ports Policy #1

Ensure that dredging and disposal of dredged material minimize adverse effects on water quality, physical processes, marine productivity and public health.

Ports Policy #2

Obtain the widest possible public benefit from channel dredging, ensuring that designated ports and developed harbors are given highest priority in the allocation of federal and state dredging funds. Ensure that this dredging is consistent with marine environment policies.

These policies are not applicable to the South Coast Rail project because no dredging or disposal of dredged material is proposed within any DPA.

Ports Policy #3

Preserve and enhance the capacity of Designated Port Areas (DPAs) to accommodate water-dependent industrial uses, and prevent the exclusion of such uses from tidelands and any other DPA lands over which a state agency exerts control by virtue of ownership, regulatory authority, or other legal jurisdiction.

The proposed reconstruction of the existing track, ballast and related infrastructure would result in a direct benefit to the DPAs' capacity to support water-dependent industrial uses by improving the railroad transportation infrastructure serving these ports. The South Coast Rail project would improve the load capacity on the New Bedford Main Line from Taunton to the Port of New Bedford and Fall River and provide additional freight transportation capacity to these ports. These improvements would improve the capacity of the DPAs to support water-dependent industrial uses without developing land within the DPA for non-water dependent uses.

Ports Management Principle #1

Encourage, through technical and financial assistance, expansion of water-dependent uses in designated ports and developed harbors, re-development of urban waterfronts, and expansion of visual access.

The proposed improvements within the Mount Hope Bay (Fall River) and New Bedford/Fairhaven DPAs would provide substantial financial assistance to these ports by replacing and upgrading existing rail infrastructure. These upgrades would substantially improve the load capacity of the existing tracks serving these ports increasing the capacity for the DPAs to serve as sea/land intermodal freight node and improve their potential to serve water-dependent industrial uses. The South Coast Rail project has been designed to avoid the construction of any non-water dependent use facilities within the DPAs while substantially improving transportation infrastructure.

The proposed track reconstruction would not adversely affect public views of the shoreline because the work is limited to the reconstruction of existing at-grade railroad infrastructure. No new stations or layover facilities are proposed in any DPA.

4.18.6.7 Public Access

Public Access Policy #1

Ensure that developments proposed near existing public recreation sites minimize their adverse effects.

Public Access Management Principle #1

Improve public access to coastal recreation facilities and alleviate auto traffic and parking problems through improvements in public transportation. Link existing coastal recreation sites to each other or to nearby coastal inland facilities via trails for bicyclists, hikers, and equestrians, and via rivers for boaters.

Redevelopment of commuter rail facilities in Fall River and New Bedford would provide mass transit access to coastal recreational facilities. A station in Fall River is planned to directly service the Battleship Cove Historical Park. Commuter rail service between these coastal areas and Boston would help to alleviate commuter automobile traffic and parking problems. The developed nature of the coastal areas in the project area is not suitable for trail development. The rail embankment does not have sufficient width to incorporate a trail system, and the proximity to high speed rail traffic would not be prudent from a safety perspective. The use of existing, active rail segments within the Coastal Zone does not preclude development of any proposed public access paths in this area.

Public Access Management Principle #2

Increase capacity of existing recreation areas by facilitating multiple uses and by improving management, maintenance and public support facilities. Resolve conflicting uses whenever possible through improved management rather than through exclusion of uses.

This Management Principle is not applicable to the alternatives.

Public Access Management Principle #3

Provide technical assistance to developers of private recreational facilities and sites that increase public access to the shoreline.

This Management Principle is not applicable to the alternatives.

Public Access Management Principle #4

Expand existing recreation facilities and acquire and develop new public areas for coastal recreational activities. Give highest priority to expansions or new acquisitions in regions of high need or limited site availability. Assure that both transportation access and the recreational facilities are compatible with social and environmental characteristics of surrounding communities.

This Management Principle is not applicable to the alternatives.

4.18.6.8 Energy

Energy Policy #1

For coastally dependent energy facilities, consider siting in alternative coastal locations. For non-coastally dependent energy facilities, consider siting in areas outside of the coastal zone. Weigh the environmental and safety impacts of locating proposed energy facilities at alternative sites.

This policy is not applicable to the alternatives.

Energy Management Principle #1

Encourage energy conservation and the use of alternative sources such as solar and wind power in order to assist in meeting the energy needs of the Commonwealth.

The proposed project would support this Management Principle by encouraging the use of public transportation and reducing dependency on automobiles. This project would provide the opportunity to use alternative energy sources such as wind or solar power at the proposed stations or for future transit-oriented development.

4.18.6.9 Ocean Resources

Ocean Resources Policy #1

Support the development of environmentally sustainable aquaculture, both for commercial and enhancement (public shellfish stocking) purposes. Ensure that the review process regulating aquaculture facility sites (and access routes to those areas) protects ecologically significant resources (salt marshes, dunes, beaches, barrier beaches, and salt ponds) and minimizes adverse impacts upon the coastal and marine environment.

This policy is not applicable to the alternatives.

Ocean Resources Policy #2

Extraction of marine minerals will be considered in areas of state jurisdiction, except where prohibited by the MA Ocean Sanctuaries Act, where and when the protection of fisheries, air and marine water quality, marine resources, navigation and recreation can be assured.

This policy is not applicable to the alternatives.

Ocean Resources Policy #3

Accommodate offshore sand and gravel mining needs in areas and in ways that will not adversely affect shorelines areas due to alteration of wave direction and dynamics, marine resources and navigation. Mining of sand and gravel, when and where permitted, will be primarily for the purpose of beach nourishment.

This policy is not applicable to the alternatives.

4.18.6.10 Growth Management

Growth Management Principle #1

Encourage, through technical assistance and review of publicly funded development, compatibility of proposed development with local community character and scenic resources.

The proposed restoration of passenger rail service to Fall River and New Bedford is compatible with the local character and scenic resources and Harbor Master Plan. Fall River and New Bedford are preparing Master Plans that incorporate commuter rail service. Additional information on the project's smart growth corridor plan and the compatibility of the proposed development with the surrounding land uses can be found in the *South Coast Rail Economic Development and Land Use Corridor Plan.*[2]

Growth Management Principle #2

Ensure that state and federally funded transportation and wastewater projects primarily serve existing developed areas, assigning highest priority to projects that meet the needs of urban and community development centers.

The Build Alternatives would improve the transportation options for the existing developed areas of Fall River and New Bedford, and link these areas with the developed urban centers of Boston and Taunton. Enhancing transportation choice is one of the sustainable development principles that is addressed in the *South Coast Rail Economic Development and Land Use Corridor Plan.*[3]

Growth Management Principle #3

Encourage the revitalization and enhancement of existing development centers in the coastal zone through technical assistance and federal and state financial support for residential, commercial and industrial development.

---

[2] Commonwealth of Massachusetts. 2009. South Coast Rail Economic Development and Land Use Corridor Plan, DRAFT June 29, 2009. Executive Office of Transportation and Public Works, and Executive Office of Housing and Economic Development. Prepared by Goody Clancy: Boston.

[3] Commonwealth of Massachusetts. 2009. South Coast Rail Economic Development and Land Use Corridor Plan, DRAFT June 29, 2009. Executive Office of Transportation and Public Works, and Executive Office of Housing and Economic Development. Prepared by Goody Clancy: Boston.

The Build Alternatives are consistent with this is policy since improvement of transportation options serving Fall River and New Bedford would encourage residential, commercial and industrial development within these coastal communities. Transit-oriented development is specifically addressed in the *South Coast Rail Economic Development and Land Use Corridor Plan.*[4]

4.18.6.11 Summary

Depending on the alternative selected, the project is expected to require several licenses for bridges, stations and layover facilities. Additional approvals would be required for bridge, track and ballast improvements at existing railroad crossings of non-tidal rivers and streams. The jurisdiction of many of these crossings would be determined during further consultation with DEP and the United States Coast Guard.

The alternatives are anticipated to comply with the policies and principles of the Massachusetts Coastal Zone Management Program. The alternatives would support water-dependent industrial uses within the New Bedford and Mt. Hope Bay DPAs by maintaining a critical transportation system supporting these uses.

The Build Alternatives would require a Federal Consistency Certification under the Massachusetts Coastal Zone Management Plan. It is anticipated that the alternatives would be consistent with the applicable policies.

4.18.7 Planning for Sea Level Rise

The Secretary's Certificate on the DEIR and the Waterways Regulations at 310 CMR 9.37(2) require MassDOT to consider potential sea level rise in designing and licensing projects subject to Chapter 91.

The Massachusetts Climate Change Adaptation Report prepared by the Executive Office of EEA and the Office of Coastal Zone Management provides a comprehensive review of potential sea level rise in Massachusetts. This report considered the potential changes in sea level based on several generally accepted climate models and their predictions representing a range of model inputs (i.e., high and low emission rates, precipitation, atmospheric CO_2 and temperatures). Based on this analysis the report cites a potential change in sea level of 8 to 16 inches (0.6 to 1.6 feet) by 2050 and approximately 23 to 79 inches (1.9 to 6.6 feet) by 2100.

The South Coast Rail project elements subject to licensing and therefore required to comply with 310 CMR 9.37(2) are limited to certain non-tidal river and stream crossings and the Weaver's Cove East Layover Facility. The majority of the non-tidal river and stream crossings is not adjacent to the shoreline and would not be expected to be subject to inundation due to a sea level rise of up to the 16 inches predicted by 2050.

The Weaver's Cove East Layover Facility would be located approximately 20 feet above the current shoreline and would not be expected to experience inundation even under the highest predicted sea level rise of 6.6 feet by 2100.

[4] Ibid.

5 INDIRECT EFFECTS AND CUMULATIVE IMPACTS

5.1 INTRODUCTION

MassDOT's stated purpose of the South Coast Rail project is to more fully meet the existing and future demand for public transportation between Fall River/New Bedford and Boston, Massachusetts to enhance regional mobility, while supporting smart growth planning and development strategies in affected communities.

The South Coast region includes 31 Massachusetts communities with a combined population of approximately 740,000. The regional population is projected to grow to more than 928,000 by 2035, making the South Coast one of the fastest growing regions of the state. As documented in the *South Coast Rail Economic and Land Use Corridor Plan*[1] (Corridor Plan), the South Coast Rail project is anticipated to result in economic benefits and growth in jobs and households within the South Coast region. While these changes are economically beneficial, induced growth is likely to affect land use and other resources. MassDOT has therefore incorporated smart growth planning into the project to provide communities with the opportunity to organize new growth and direct it away from sensitive areas of ecological value. The region envisions a future with renewed and expanded urban centers, new walkable neighborhoods, and natural areas that are preserved for future generations.

The following indirect effects and cumulative impacts analysis is consistent with the CEQ and other agency guidance documents, including:

- Considering Cumulative Effects Under the National Environmental Policy Act[2]
- Guidance on the Consideration of Past Actions in Cumulative Effects Analysis[3]
- Interim Guidance: Questions and Answers Regarding Indirect and Cumulative Impact Considerations in the NEPA Process[4]
- Consideration of Cumulative Impacts in EPA Review of NEPA Documents[5]

The indirect (or secondary) effects analysis is focused on induced household and employment growth that may result from increased transportation access in the South Coast region. The cumulative impact analysis evaluates changes within the study area as a result of past, present, and reasonably foreseeable future actions combined with the South Coast Rail project.

5.1.1 Regulatory Context and Definitions

The requirement to analyze the direct, indirect and cumulative impacts of proposed federal actions was established in the CEQ regulations implementing NEPA. This section summarizes key definitions and

requirements related to indirect effects and cumulative impacts from the CEQ NEPA regulations, agency guidance documents, and court decisions. It should be noted that "effects" and "impacts" as used in the CEQ regulations are synonymous and can be positive or negative (40 CFR 1508.8).

5.1.1.1 Direct Effects

According to the CEQ's regulations implementing NEPA, direct effects are "caused by the action and occur at the same time and place" (40 CFR 1508.8). Direct effects are typically well understood and predictable. Examples of common direct effects for transportation projects include residential and business displacements, filling of wetlands to construct rail infrastructure, and removal of a historic structure.

5.1.1.2 Indirect Effects

Indirect effects "are caused by the action and are later in time and/or farther removed in distance, but are still reasonably foreseeable." Indirect effects "may include growth-inducing effects and other effects related to induced changes in the pattern of land use, population density or growth rate, and related effects on air and water and other natural systems, including ecosystems" (40 CFR 1508.8). The National Cooperative Highway Research Program's (NCHRP) *Report 466: Desk Reference for Estimating the Indirect Effects of Proposed Transportation Projects* identifies two primary types of indirect effects—induced growth (or growth influencing) and encroachment-alteration.

Induced growth type indirect effects are changes in the location and/or magnitude of future development attributed to changes in accessibility caused by the transportation project. Accessibility is the ease of movement from an origin (to all other places) or as a destination (from all other places). Transportation improvements change accessibility by reducing the time cost of travel between destinations. Changes in accessibility can affect the location decisions of residents and businesses if favorable economic, regulatory and infrastructure conditions are also supportive of new development. An example of an induced growth type indirect effect is commercial development occurring around a new rail station and the environmental impacts associated with this development. The transportation project is a necessary condition for this development to occur (by providing new or improved access), but is not a sufficient condition. In order for the development to occur, it also requires favorable conditions that may include:

- economic conditions that support development (e.g., markets, acceptable rate of return on investment in land purchase, design, construction, and other costs);
- zoning and other land use controls and policies suitable for the type of development suggested by market conditions;
- other infrastructure that supports development (e.g., water and sewer service); and
- amenities (e.g., good schools, access to recreational opportunities).

Encroachment-alteration indirect effects are physical, chemical or biological changes in the environment as a result of the project removed in time or distance from the direct effects. An example of an encroachment-alteration indirect effect would be a long-term decline in the viability of a population of a particular species as a result of habitat fragmentation caused by the project. Encroachment-alteration effects such as habitat fragmentation or changes in water quality are addressed in the resource-specific chapters of this FEIS/FEIR (e.g. Biodiversity, Wildlife and Vegetation, Water Resources, etc.).

Regardless of the type of indirect effect, case law has established that NEPA documents need to address indirect effects that are likely or probable.[6] Speculation on indirect effects that are merely possible is not required. In Sierra Club v Marsh 769 F. 2d 763 (1985), the Court set forth a three-part test to determine if a particular set of impacts is definite enough to take into account, or too speculative to warrant consideration:

- With what confidence can one say that the impacts are likely to occur?
- Can one describe them now with sufficient specificity to make their consideration useful?
- If the decision maker does not take them into account now, will the decision maker be able to take account of them before the agency is so firmly committed to the project that further environmental knowledge, as a practical matter, will prove irrelevant to the government's decision?

Where economic development is an explicit part of the project purpose, the indirect effects analysis should also consider the environmental effects of this development.

5.1.1.3 Cumulative Impacts

A cumulative impact is "the impact on the environment which results from the incremental impact of the action when added to other past, present, and reasonably foreseeable future actions regardless of what agency (Federal or non-Federal) or person undertakes such other actions. Cumulative impacts can result from individually minor but collectively significant actions taking place over a period of time" (40 CFR 1508.7). According to the FHWA's *Interim Guidance: Questions and Answers Regarding the Consideration of Indirect and Cumulative Impacts in the NEPA Process,*[7] cumulative impacts include the total of all impacts to a particular resource that have occurred, are occurring, and will likely occur as a result of any action or influence, including the direct and reasonably foreseeable indirect impacts of a proposed project.

Cumulative impact analysis is inherently resource-specific and frequently regional in scale. CEQ's *Considering Cumulative Effects under the National Environmental Policy Act* envisions cumulative impact analysis as a tool for evaluating the implications of project-level decisions on the status or health of regional resources. According to the USEPA, an adequate cumulative effects analysis of impacts that are due to past, present, and reasonably foreseeable future actions needs to consider the following factors: 1) whether the environment has been degraded, and if so, to what extent; 2) whether ongoing activities in the area are causing impacts; and 3) the trends for activities and impacts in the area.[8]

To determine what information is relevant to include in a cumulative impact analysis, sufficient scoping and research should reveal those actions that are "relevant to reasonably foreseeable significant adverse impacts" and are "essential to a reasoned choice among alternatives," and can be obtained without exorbitant cost.[9]

A cumulative impact analysis should identify:

[9] Connaughton, J.L., "Guidance on the Consideration of Past Actions in Cumulative Effects Analysis." Memorandum to Heads of Federal Agencies. June 24, 2005.

- the area in which the effects of the proposed project will be felt;
- the impacts that are expected in that area from the proposed project;
- other past, present, and reasonably foreseeable actions that have or are expected to have impacts in the area;
- the impacts or expected impacts from these other actions; and
- the overall impact that can be expected if the individual impacts are allowed to accumulate.

"Reasonably foreseeable future actions" for the purpose of cumulative impact analysis are probable or likely, not merely possible.

5.1.2 Massachusetts Environmental Policy Act Requirements

The MEPA regulations at 301 CMR 11.07(6) (h) require that an EIR evaluate the cumulative effects of a proposed project. The Secretary's Certificate on the ENF required that the DEIR include several specific analyses and information, listed below.

- The DEIR should present an analysis of the secondary and cumulative impacts, both positive and negative, related to induced growth in communities affected by the rail and bus alternatives, and explain how implementation of the Corridor Plan is expected to mitigate potential adverse impacts.
- Each of the alternatives should be evaluated under three different scenarios, including the full build with mitigation, i.e., implementation of the Corridor Plan. The full range of potential environmental impacts associated with implementation of this plan should be evaluated including impacts to biodiversity, wetlands, endangered species, air quality and greenhouse gas (GHG) emissions, transportation, municipal infrastructure, and water resources.
- The DEIR should define the study area for evaluation of secondary growth impacts and explain the rationale for the boundaries selected.
- The DEIR should discuss different scenarios for induced growth and explain how this has been incorporated in modeling for the alternatives analysis
- The DEIR should discuss different scenarios and include projections of where growth is expected to occur, and at what rate, under each of the alternatives.
- The DEIR should identify areas where sprawl may occur under certain alternatives and include mitigation plans to concentrate development and protect natural resources.
- The DEIR should evaluate the alternatives on the basis of other smart growth principles, including conservation of open space and use of existing infrastructure.
- The DEIR should discuss the trade-offs inherent in project alternatives, such as increased impacts on certain resources for environmental benefits in other areas.

- The DEIR should include details on specific mechanisms that will be used to ensure that the smart growth goals of the project will be realized, including funding commitments and mechanisms for conservation of PPAs and acquisition and development of PDAs.

- The DEIR should describe in detail how land use will be controlled and priority conservation areas permanently protected.

- The DEIR should clarify indicators and metrics to be used for evaluation of smart growth, and propose a long-term monitoring and evaluation plan.

- The DEIR should describe specific strategies and resources, including state funding commitments, to ensure successful implementation of the Corridor Plan.

- The DEIR should describe the tools and resources needed by individual communities to take advantage of the economic development potential of the proposed rail line in a manner that protects critical resources and is consistent with the Commonwealth's Sustainable Development Principles.

- The DEIR should also include information on any municipal land use or policy commitments that have been made.

- With respect to secondary growth impacts, each alternative should be analyzed under three different scenarios: (1) the baseline condition, which evaluates environmental conditions in the absence of the proposed rail under the assumption that current travel and development patterns continue and there are no changes in municipal zoning, (2) build without mitigation, which evaluates impacts, including induced growth, associated with each alternative in the absence of transit-oriented development (TOD), green building, zoning changes, transfer of development rights, wetlands restoration, habitat protection, or other mitigation measures, and (3) build with mitigation, which evaluates impacts associated with the alternatives assuming implementation of the Corridor Plan, TOD in and around the stations, habitat protection (including priority protection areas, PPAs) and other proposed mitigation.

- The DEIR should include an assessment of costs associated with implementation of the smart growth aspects of the project for each alternative, to fully understand the overall costs and rationale for selection of alternatives.

The Secretary's Certificate on the DEIR requested additional information on smart growth mitigation measures and the implementation of the Corridor Plan. This information is provided in Section 5.5.

5.1.3 Organization of this Chapter

Section 5.2 presents the methods used to assess indirect effects and cumulative impacts for each of the alternatives. Section 5.3 presents indirect effects assessment for the No-Build Alternative and the build alternatives under two scenarios—without smart growth measures, and with the implementation of the South Coast Rail Economic Development and Land Use Corridor Plan (the Plan). Section 5.3 also provides a description of the Plan and the smart growth measures that are included in the South Coast Rail alternatives. Section 5.4 provides an analysis of the cumulative impacts of the South Coast Rail alternatives on natural, social, cultural, and physical resources.

5.2 METHODOLOGY

5.2.1 Indirect Effects

This section identifies the methodology and assumptions for the analysis of indirect effects.

5.2.1.1 Introduction

Potential indirect effects (beneficial and adverse) of the Build Alternatives were evaluated with and without smart growth measures (including TOD). The Corridor Plan was the guiding land use development plan for this analysis. The Commonwealth provides a number of grant programs that support smart growth from economic development to land preservation. The Massachusetts Executive Office of EEA has developed a Smart Growth/Smart Energy Toolkit,[10] which includes tools, model bylaws, and other resources to help local planners control sprawl/encourage smart growth.

The analyses consider reasonably foreseeable indirect effects, from project initiation in 2016 through the planning period ending in 2035, from implementing the South Coast Rail project. Induced growth that would result from the Build Alternatives includes the creation of new residential development and jobs. In order to assess the indirect effects of this induced growth, two scenarios were developed to allocate growth in the South Coast region. The first scenario, Scenario 1, allocates induced growth under business as usual conditions, includes baseline conditions, and assumes that induced growth would occur in a traditional pattern.

The second scenario, Scenario 2, assumes that growth would be directed to Priority Development Areas (PDAs) and away from PPAs, based on the planning efforts of each municipality in the South Coast region. It includes the baseline growth, project-induced growth, and goals of the Corridor Plan. For some analyses, Scenario 2 was evaluated based on high and low levels of implementation of smart growth measures. The allocation of each growth scenario was then viewed in terms of its impact on natural, social, cultural, and physical resources as compared to the No-Build Alternative.

Each analysis relies on data provided in the Corridor Plan, information provided by the three regional planning agencies (RPAs) in the South Coast region, and information developed by MassDOT. The analysis identifies potential changes in land use, infrastructure requirements (water, sewer, etc.) under each scenario and the social and economic environment that would likely result from growth induced by the new transit system. Based on the anticipated changes in land use, potential impacts to selected environmental resources are estimated.

Each of the two build scenarios have been evaluated regionally for a range of potential impacts, based on the option with the largest projected ridership: the Stoughton Electric Alternative. The Whittenton Alternative was not evaluated, because its effects would be similar in magnitude and location to the Stoughton Electric Alternative. The indirect effects analysis in this FEIS/FEIR therefore assumes that these two alternatives are equivalent because the same level of induced growth distributed among the municipalities is expected.

5.2.1.2 Study Area

The study area for the indirect effects assessment is based on the area where induced growth would be likely to occur as a result of the South Coast Rail project (the "commuteshed"). The commuteshed includes the 31 Massachusetts communities in the Corridor Plan and four communities in southeastern Rhode Island that could potentially be served by a rail station in Fall River (Table 5.2-1). All communities are within a reasonable commuting distance of the proposed rail corridors and transit stations.

Table 5.2-1 Indirect Effects Study Area Municipalities

Regional Planning Agency	Municipalities	
Metropolitan Area Planning Council	*Canton*[1]	*Sharon*
	Foxborough	*Stoughton*
Old Colony Planning Council	*Bridgewater*	
	Easton	
	Stoughton[2]	
Southeast Regional Planning and Economic Development District	Acushnet	New Bedford
	Attleboro	*North Attleborough*
	Berkley	*Norton*
	Dartmouth	Raynham
	Dighton	Rehoboth
	Fairhaven	Rochester
	Fall River	Seekonk
	Freetown	Somerset
	Lakeville	Swansea
	Mansfield	Taunton
	Marion	Wareham
	Mattapoisett	Westport
	Middleborough	
Rhode Island	Bristol	Tiverton
	Portsmouth	Warren

1 Communities in italics are the "SCR 10" northern communities.
2 Stoughton is shared between Metropolitan Area Planning Council and Old Colony Planning Council.

5.2.1.3 No-Build (Enhanced Bus) Alternative

Conditions under the future No-Build Alternative (in 2035), based on the regional plans of the MAPC, the OCPC, and SRPEDD, have been developed to establish baseline conditions by which to assess the effects of the Build Alternatives under the scenarios discussed below. Smart growth measures already adopted by communities, irrespective of the South Coast Rail project, have also been incorporated in this baseline.

5.2.1.4 Scenario 1 – Indirect Effects without Smart Growth Measures

The analysis considers reasonably foreseeable indirect effects from implementing the South Coast Rail project without smart growth strategies, including TOD. Induced growth, both within immediate proximity of station areas and in nearby communities that are served by each station, has been estimated based on literature review and regional growth projections:

- Growth projections of jobs and households from SRPEDD, OCPC, and MAPC;
- Induced growth estimates of jobs and households from the Transportation Economic Development Impact System Model (TREDIS)[11] were projected by calculating the percentage of total 2030 Scenario 1 growth comprised by each municipality's 2030 No-Build Alternative and 2030 Scenario 1 growth projections, and applying the municipality-specific percentage from the 2035 No-Build Alternative to project 2035 Scenario 1 growth;
- Distribution of jobs and households in the region from the Corridor Plan and SRPEDD, MAPC, OCPC, and Regina Villa Associates; and
- Job growth projections were not previously available for Dartmouth and Wareham. Therefore the following assumptions were applied to calculate projected 2035 job growth in these municipalities. In order to arrive at projected 2035 job growth, the 2000 municipal population was multiplied by the average 2035 job growth per capita of nearby towns.

MassDOT has developed projections for induced growth in jobs and households broken down into three regions: Suffolk County/Cambridge, SCR 10[12] (the northern communities) and SCR 21[13] (the South Coast communities). Projections were also made for the four Rhode Island communities that are expected to have commuters utilizing the potential new transit service. This is growth that would not occur without the transit investment. In 2010, MassDOT prepared new regional projections of population and employment growth. The RPAs then updated their projections at the municipal level based on these revised figures.

Induced Jobs

The TREDIS model provides projections for new jobs according to the North American Industry Classification System (NAICS) employment classification system. Comparisons between the location quotients of the current distribution of jobs by consolidated NAICS job codes with the estimated distribution of the induced jobs allowed for projections to be made for the number and sub-regional geographic distribution of new jobs.

Data used to inform the allocation include:

- ridership data provided by the Central Transportation Planning Staff (CTPS) from the Boston Region Metropolitan Planning Organization, RPA demographic projections, and regional economic data sets;
- existing employment centers by sector: for example, the communities with the highest regional share of manufacturing jobs are expected to attract the majority of new manufacturing jobs;
- current trends: communities that have strong growth in particular job sectors are expected to continue attracting jobs from those sectors; and

[11] The Transportation Economic Development Impact System Model (TREDIS) is a web-based analysis system used to analyze planned transportation investments. The model works by utilizing a series of modules that compare project impacts and project benefits.

[12] SCR 10 communities: Attleboro, Bridgewater, Canton, Easton, Foxborough, Mansfield, North Attleborough, Norton, Sharon, and Stoughton.

[13] SCR 21 communities: New Bedford, Acushnet, Berkley, Dartmouth, Dighton, Fairhaven, Fall River, Freetown, Lakeville, Marion, Mattapoisett, Middleborough, Raynham, Rehoboth, Rochester, Seekonk, Somerset, Swansea, Taunton, Wareham, and Westport.

- zoning, infrastructure capacity, land availability, and transportation access: industrial parks and other job centers that have the appropriate zoning, infrastructure, and land available for expansion are likely to capture a significant share of this new growth.

To estimate the number of induced jobs under Scenario 1, total jobs were first projected by the model for the sub-regions and then distributed to the municipal level.

Unlike housing, which tends to be distributed more diffusely throughout the region, jobs are more strongly tied to existing job centers and less so to proposed station sites. Manufacturing jobs, for example will be clustered in industrial parks and other areas so zoned. Health occupations tend to congregate in hospitals and other medical campus settings. Consolidated NAICS job sector codes were used to group jobs into larger categories. For example, the NAICS codes between 541 and 551 were combined to create the Professional, Scientific, and Technical Services category—one of the sectors estimated to experience significant growth related to the restoration of transit service. A job share for each consolidated NAICS sector was then calculated for each city and town.

SRPEDD analyzed labor and workforce data for the consolidated job sectors for all communities between 2001 and 2008. An eight-year sector average was developed for each category for each municipality. These data reveal which communities have clusters of industry and, because it is an average over the eight-year time period, smooths out any anomalous years and captures recent trends. The eight-year jobs sector average by community was used to allocate the induced jobs in SCR 10 and SCR 21 communities.

To incorporate the expected influence of the transportation routes, a normative scoring system was used to take into account the relative influence the route alternative is likely to have on a given municipality. This system was developed by a working team consisting of the RPAs and project consultants. A community designated as likely to be strongly influenced, moderately influenced, or to experience limited influence. Communities were designated as strongly influenced if they would contain a new station or if the access to transportation service is improved. Moderate influence designations went to communities likely to experience less significant influence—those that are reasonably close to greatly expanded service or those communities that would see modest improvements in service. Finally, communities were assigned to limited influence if little or no change is expected to existing transportation service or if they are remotely located from new service.

Fifty percent of the induced jobs assigned to the communities that would experience a limited influence were then reassigned equally to the strongly influenced communities. The limited influence communities are the farthest away from the service improvements and would have the least benefit from transit improvements. On the other hand, the strongly influenced communities are expected to see more housing development and job opportunities as a result of the South Coast Rail project.

Because the TREDIS model's study area did not include any communities in Rhode Island, an estimate of the induced job growth for the Rhode Island communities was made by calculating the proportional growth the communities' Massachusetts neighbors would receive. Bristol and Portsmouth were assigned the same growth rate as Swansea; Tiverton to Westport; and Warren to Seekonk.

Induced Households

Similar to the effects on job creation, expanded and improved transportation access would increase the potential for new households to locate in the region. Some households are likely to be attracted to new

employment opportunities. Other households would be attracted to the relatively less expensive housing markets farther south of the Greater Boston area. Expected household growth for each of the alternatives was calculated by the Economic Development Research Group, Inc. A summary report, including a description of their methodology, is included in Appendix 5.2-A.

Factors considered in allocating induced households included:

- Ridership origination. Using ridership data produced by CTPS, areas that are now within a 20-minute drive of new stations are expected to generate new households. Communities within the northern portion of the corridor are already within a 20-minute commute to the stations of the Old Colony Line to the east and the Northeast Corridor to the west. Induced growth in this geography is more likely to be concentrated closer to new transit stations.

- Service time. Train and bus service times double in frequency north of the Southern Triangle (in Taunton).

- Housing costs. Housing costs generally decrease south of Mansfield providing more opportunity for home ownership and larger homes.

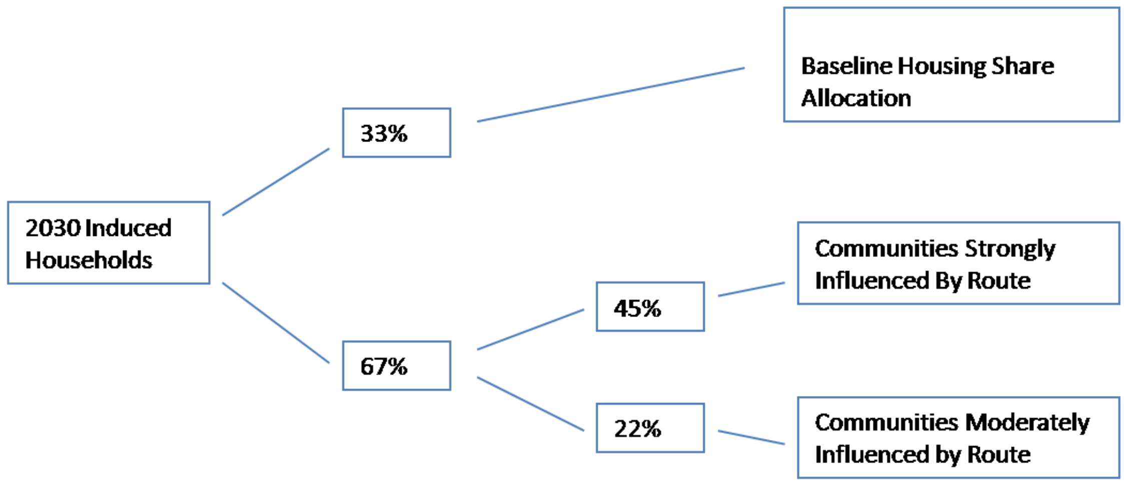
- Employment center midpoints. Large concentrations of jobs are found in Greater Boston, Providence, Fall River, New Bedford, Taunton, and Attleboro. Households with two workers often seek to live in the midpoint for the two commutes.

- Population concentration and growth trends. New household locations are likely to follow existing growth trends and are less likely to be absorbed into communities approaching build out.

- Zoning, infrastructure and land availability. The availability of land zoned for residential development and infrastructure capacity to support new development are other important factors. Some communities have zoning and capacity for additional multifamily units, while the more semi-rural communities are zoned for large lots and rely on private wells and septic tanks for wastewater disposal.

An expert team of RPA representatives and project consultants arrived at a general agreement at a working session on August 26, 2009, on how to use household concentrations over time to capture trends in housing location throughout the South Coast region. Similar to the jobs allocation, it uses a normative assessment of how likely each community is to be affected by the various transportation routes. Communities were designated as likely to be strongly influenced, moderately influenced, or to experience limited influence.

The following flowchart illustrates how households were allocated under Scenario 1.



Because household growth estimates are broken into the two SCR sub-regions, the allocation at the municipal level was undertaken for the SCR 10 and SCR 21 communities separately. First, each municipality's share of the households in 2010 was calculated based on U.S. Census data. Second, each municipality's share of projected growth in households from 2010-2035 was calculated. These two shares were averaged to create a baseline housing share that captures existing housing concentrations and projected growth in households. One-third (33 percent) of the induced households were allocated according to this baseline share. This part of the allocation depends on existing and projected regional housing characteristics and not on any specific alternative. The remaining two-thirds (67 percent) were allocated according to the expected influence of the Build Alternatives. This process takes into account residential development opportunities in some communities within easy drive-time distances of the new stations. At the same time, this approach discounts the expected impacts for the communities farther away from a particular route.

Each community was assigned a designation of strongly influenced, moderately influenced, or limited influence for each of the Build Alternatives. The RPAs and project consultants assigned these values to South Coast study area municipalities. Communities were designated as strongly influenced if they would contain a new station or if the access to transportation service is improved. Moderate influence designations went to communities likely to experience less significant impacts—those that are reasonably close to greatly expanded service or those communities that would see modest improvements in service. Finally, communities were assigned to limited influence if little or no change is expected due to local transportation service or if they are remotely located from new service. The remaining two-thirds of the households were allocated based on these designations—45 percent of the original total went to the strongly influenced communities and the remaining 22 percent of the original total were allocated to the moderately influenced communities. Previously, 33 percent of the households were allocated according to the baseline share, which results in a 100 percent allocation of households.

An estimate of the induced household growth for the Rhode Island communities was made by calculating the proportional growth the communities' Massachusetts neighbors would receive. Bristol

and Portsmouth were assigned the same growth rate as Swansea; Tiverton to Westport; and Warren to Seekonk.

5.2.1.5 Scenario 2 – Indirect Effects with Smart Growth Measures

The Corridor Plan outlines a future of more sustainable development patterns across the South Coast region. This smart growth plan envisions housing and jobs clustered in areas appropriate for development, while preserving important natural resource lands such as fields, forests, farmland, and wetlands. Outcomes of the Corridor Plan would include the creation of new multifamily housing developments and neighborhoods of tightly clustered single family homes in closer proximity to transportation options and mixed use centers that contain professional offices, retail stores, restaurants, and employment opportunities. Denser, mixed use development patterns would yield measurable benefits for the environment. Local governments can support the smart growth vision by altering current zoning laws to permit denser development and streamline permitting requirements. The Commonwealth supports smart growth efforts through grant programs and technical advice. Information on its Smart Growth/Smart Energy Program can be found at http://www.mass.gov/envir/smart_growth_toolkit/. USEPA also as programs supporting smart growth, see: http://www.epa.gov/dced/index.htm. The Corridor Plan identifies PDAs and PPAs, capturing the strongest candidates for development and preservation, as shown on the Corridor Map (Figure 5-1). The goals outlined on this map can be realized through coordinated state investments and local actions, such as rezoning and regulatory changes.

As part of the environmental review process the impacts of the No-Build Alternative were compared to the Build Alternatives. There are many potential smart growth scenarios that could unfold through 2035. It is impossible to predict with any certainty the future development or preservation outcomes for particular PPAs. However, it is possible to explore one theoretical smart growth scenario for the purposes of comparing the impacts between the No-Build and Build Alternatives. Any such exercise necessarily requires a series of assumptions to be made regarding the type and location of future growth. The following assumptions were made before constructing the smart growth model:

- Infrastructure constraints will be overcome within reason; the Commonwealth help will support infrastructure investments to realize more compact development;
- Local rezoning can be expected to occur for PDAs to accommodate higher levels of development and different permitted uses; and
- A greater mix of multifamily and smaller-lot single-family units will be developed under the smart growth scenario.

This analysis considers the reasonably foreseeable indirect effects of the South Coast Rail project with smart growth strategies (i.e., measures that MassDOT can implement and/or growth management strategies that are anticipated to be adopted by study area municipalities by 2035). It was assumed that proposed stations are designed to optimize TOD opportunities with the full range of smart growth measures as provided in the Corridor Plan and regional long-range plans.

The smart growth scenario includes all projected baseline (No-Build) and induced growth in jobs and households across the South Coast region. A working group of consultants and planners from the three RPAs constructed this theoretical model with the assistance of Geographic Information Systems (GIS) mapping techniques and ground-truthing by regional planners.

Under the smart growth scenario, jobs were allocated by the RPAs into traffic analysis zones (TAZs) based on the share of jobs projected in 2035. This allocation will permit future impact analyses of the induced jobs in the context of traffic and GHG emissions. Growth was redistributed using the process described in this section.

At the heart of the Corridor Plan is the Corridor Map, which identifies appropriate places for development and preservation (PDAs and PPAs). The smart growth model uses these districts as the base geographies for the reallocation of housing and jobs. All state-endorsed PDAs were designated to receive a portion of the reallocation, as were some regionally identified PDAs. Regional PDAs were included in the model if they were particularly well suited for smart growth development, such as downtowns. If a community did not have a state-endorsed PDA, the RPA included a regional priority area from the community that, in their professional judgment, represented the strongest opportunity for smart growth development.

The literature examining smart growth policies and planning has shown that approximately 30 percent of households[14] are attracted to the characteristics that comprise smart growth development—chiefly, compact, mixed-use development, and proximity to public transit, among other benefits. Originally, MassDOT proposed to reallocate 30 percent of the projected growth from the PPAs and Neutral Areas into PDAs. Reflecting the proposed state and local smart growth actions as identified in the Corridor Plan focus on the priority areas, the 30 percent reallocation assumption was modified to reflect this more nuanced approach to development and preservation activities. The working assumption is to shift 50 percent of the current predicted growth (baseline plus induced) of households and jobs in PPAs and 25 percent of the current predicted growth (baseline plus induced) of households and jobs in the neutral areas to the PDAs. This actually results in slightly less than the original 30 percent reallocation because less growth has been projected for the outlying protection areas.

Figure 5-2 illustrates how households and jobs were allocated under Scenario 2. The following "rules" were used in the Scenario 2 re-allocations:

- Acres of developable land were calculated for the PDAs.
- Only PDAs that have potential for residential or mixed-use development were considered for the reallocation of households and PDAs that are solely residential did not receive any reallocated jobs.
- The RPA current trends projections from 2010 to 2035 include households at the TAZ level. For each TAZ that falls outside a PDA, 30 percent of the projected growth from 2010 to 2035 under the No-Build scenario was redirected to the PDAs.
- A TAZ was considered within a PDA if 50 percent or more of its land area falls within the PDA border.
- If a municipality cannot hold projected growth in its PDA, a transfer was made to another PDA. The first transfer was intra-municipal. New households were shifted from non-PDA TAZs to the PDAs within a municipal boundary.

Figure 5-2 Household and Job Allocation Model under Scenario 2

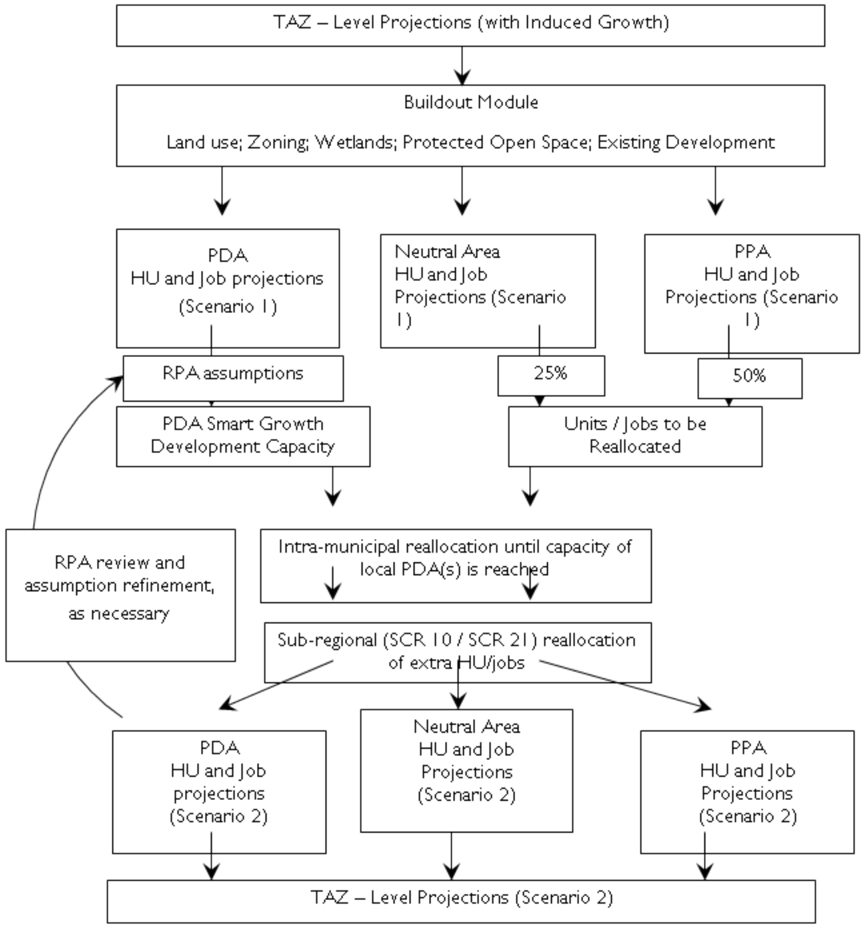

Table 5.2-2 Metrics Used to Evaluate Environmental Impacts of Induced Growth (per household)

	Metric[1]			
Resource	**Scenario 1: No Smart Growth**	**Scenario 2: Smart Growth (high scenario)**	**Scenario 2: Smart Growth (low scenario)**	**Sources**
GHG Emissions	11.83 tpy	-	11.83 tpy	eQUEST
Land Conversion[2]	0.56 acre	0.39 acre	0.44 acre	Losing Ground and American Journal of Public Health
Loss of Farmland[3]	0.13 acre	0.091 acre	0.10 acre	Losing Ground and American Journal of Public Health
Loss of Forest Land[4]	0.30 acre	0.21 acre	0.24 acre	Losing Ground and American Journal of Public Health
Loss of Wetland	7.35 sf	5.15 sf	5.81 sf	MassGIS
Biodiversity Impact	3:1 ratio	2.10:1 ratio	2.37:1 ratio	Losing Ground and American Journal of Public Health
Water Demand	162.5 gal	-	141.4 gal	MassDEP and USEPA[5]
Traffic	66 VMT/day	66 VMT/day	VMT/household/day	MPAC and MassGIS[6]

1 The number of households per community would be multiplied by this metric to estimate the potential future impacts, for each scenario.
2 These factors are averaged across the South Coast region. Community-specific factors are presented in Appendix 5.3-A.
3 These factors are averaged across the South Coast region. Community-specific factors are presented in Appendix 5.3-A.
4 These factors are averaged across the South Coast region. Community-specific factors are presented in Appendix 5.3-A.
5 U.S. Environmental Protection Agency. How to Conserve Water and Use it Effectively. http://www.epa.gov/nps/chap3.html (November 2009).
6 Conversion is based on municipality-specific factors prepared by MPAC, based on 16 million Registry of Motor Vehicles inspection records analyzed by MassGIS.

- Farmland. Future land development in the South Coast will likely involve the conversion of farmlands to residential and commercial uses. The Massachusetts Audubon Society's (MassAudubon) Losing Ground[15] study undertook an analysis of the conversion of farmland for new housing from 1999-2005 for the Commonwealth. This recent trend data provided an estimate of how much farmland might be consumed in each town as it absorbs new residential growth. A forecast was then made of the potential loss of farmland due to future development, based on development history and the size of a typical lot in each community in accordance with municipal zoning. Because similar data for relevant Rhode Island

[15] DeNormandie, J. (2009). *Losing Ground: Beyond the Footprint*. Lincoln, MA. Massachusetts Audubon Society.

communities was not readily available, an estimate of the potential loss of farmland there was made based on the experience of Massachusetts towns with similar residential densities.

- Wetlands. Residential housing development typically results in minor impacts to wetlands because of local, state, and federal legal protections. However, the construction of a subdivision might include new roadways, which could fill wetlands. In most cases, a developer would be required to mitigate the wetland loss by creating a wetland on another part of the property. To estimate the extent of wetland loss that could result from new residential growth, data were reviewed from a MassGIS analysis showing how land use changed between 1999 and 2005. Smart Growth developments, which are generally denser and feature multi-family housing, would reduce wetlands impacts. It is expected that the development of a typical housing unit would disturb 0.00017 acre of wetlands.

- Biodiversity. The potential effects of growth on biodiversity are difficult to quantify, but it is known that development destroys habitat and has a disruptive effect on ecological processes. The protection of land as open space is an important strategy. An assessment of the mixture of habitat and natural community types across a region provides insight into biodiversity. MassAudubon's Losing Ground report conducted an analysis of habitat fragmentation in USEPA ecoregions across Massachusetts. This analysis was used to estimate the direct and indirect impacts on biodiversity as a result of new development in the South Coast region. It is expected that for every 1 acre of development that 3 acres of biodiversity are impacted.

- Infrastructure. Residential housing growth will have a direct effect on communities' needs to supply or support water and wastewater infrastructure. MassDEP estimates that household water demand is approximately 65 gallons per person per day though demand does fluctuate by community. It was assumed that as new residential growth occurs, similar ratios of water and wastewater use per household will hold. Communities that rely on private wells and septic systems are not expected to bear new public costs for growth, but growth could still increase demands on constrained resources.

- Air Quality. Induced growth will result in the additional GHG emissions in the South Coast region. An analysis was conducted for a typical house constructed in the year 2035. The model provided estimated carbon dioxide emissions related a prospective home's electric and gas consumption. An analysis of the mobile source GHG emissions is presented based on a reallocation of population and employment to the TAZ level.

Assumptions for Scenario 2 (Future Growth Scenario with Smart Growth)

This scenario assumes that the measures outlined in Chapter 7 of the Corridor Plan: Implementation of the Corridor Plan are fully implemented by the state and study area municipalities. These measures have been adopted by the Development Cabinet of the administration and include implementation commitments from all Secretariats. Measures include strategic investments of discretionary state funding consistent with the Corridor Map, providing ongoing technical assistance to South Coast region municipalities to aid in changing local land use codes and regulations, creating a regional transfer of development rights (TDR) program, and capturing new tax revenues to balance state and local needs.

Strategic investments of discretionary state funding have been identified to encourage zoning and land use changes to support the Corridor Plan. Significant funding flows from the state to municipalities through a variety of grant and loan programs. By using the Corridor Plan priorities as the guide for these

investments, state agency investments will be better coordinated and will serve as an incentive that will prompt local actions consistent with the Corridor Plan. Technical assistance will be provided to expand affordable housing and economic development opportunities, open space preservation, and station area planning. A regional TDR program to steer growth into areas appropriate for development of PDAs and outside of PPAs will be created. The Commonwealth will help to support the Massachusetts Division of Fish and Wildlife's Eastern Box Turtle Conservation Plan by providing technical assistance to communities within critical areas for habitat protection. This assistance could include providing model conservation subdivision bylaws (cluster development or open space residential design bylaws) or transfer of development rights bylaws to protect critical habitat areas. Scenario 2 also includes implementing the Station Area Plans that are outlined in the Corridor Plan. TOD will cluster jobs and housing around the stations, creating new green neighborhoods. Table 5.2-3 provides a summary of build out anticipated in and around proposed transit stations.

Table 5.2-3 Station Area Development under Scenario 2

Station	Alternative	Residential (units)	Commercial (sf)
Battleship Cove	All	0	0
Dana Street	Whittenton	N/A	N/A
Easton Village	All	150-200	15,000 – 30,000
Fall River Depot	All	200	200,000
Freetown	All	200	25,000
King's Highway	All	350	250,000
North Easton	All	125	0
Raynham Place	All	400-600	90,000 – 200,000
Stoughton	All	300-350	10,000 – 25,000
Taunton	Stoughton	125-175	Complementary uses
Taunton Depot	All	150-200	0
Whale's Tooth	All	1,400	500,000

Source: Goody Clancy 2009. South Coast Rail Economic Development and Land Use Corridor Plan. Goody Clancy: Boston, MA. June 2009.
Note: The Dana Street station as part of the Whittenton Alternatives was not envisioned at the time the Corridor Plan was prepared.

Potential impacts on environmental resources that could be attributed to induced growth under the smart growth scenario in the study area include:

- Land Use. Development that is outlined in the Corridor Plan would be considered part of the smart growth scenario. It was assumed that compact, mixed-use, and infill housing development is expected to account for approximately 30 percent of induced growth, which is expected to reduce new land development by approximately 21 percent[16] for the low scenario and 30 percent for the high scenario. It is anticipated that communities which support the development of dense multi-family, clustered single-family housing, and transit-orientated development and utilize other smart growth incentives could reduce land use impacts up to 30 percent and achieve the high scenario. The low scenario entails a sizeable improvement over traditional growth patterns, but assumes that not all communities will implement smart growth policies enumerated in the Corridor Plan.

[16] Burchell, R.W. and S. Mukherj. (2003). Conventional Development Versus Managed Growth: The Costs of Sprawl. *American Journal of Public Health*, 93 (9), 1537.

- Farmland. Under the smart growth allocation, it is estimated that 21 percent fewer acres of agricultural land would be converted for development.

- Wetlands. Smart growth development, which is generally denser and features clustered and multi-family housing, would reduce wetlands impacts by an estimated 21 percent per a previous study.

- Biodiversity. To estimate how compact development patterns would reduce impacts on biodiversity, it was assumed that a 21 percent reduction in land consumption for development would have a commensurate benefit in land to support biodiversity in the South Coast region.

- Infrastructure. Smart growth development patterns are expected to reduce the consumption of water for use outdoors. However, multi-family and clustered housing are built on smaller lots and would have smaller lawns for watering and fewer paved areas to wash. It is estimated that smart growth would reduce household water consumption by approximately 13 percent.

- Air Quality. The model provided estimated carbon dioxide emissions related a prospective home's electric and gas consumption.

5.2.2 Cumulative Impacts

This section describes the methodology used to evaluate the cumulative impacts of the South Coast Rail project.

5.2.2.1 Introduction

The South Coast Rail project is anticipated to result in direct or indirect, adverse and/or beneficial effects to a range of resources, as described in Chapter 4. Additional effects may result from induced growth, as described in the indirect effects portion of this chapter. Some of the minor or major effects of the South Coast Rail project may when combined with the effects of other past, present, or future actions result in substantive impacts to environmental or social (human) resources. These combined effects are referred to as cumulative impacts and are further discussed in this section.

5.2.2.2 Methodology

Cumulative impacts of the Build Alternatives under both Scenarios 1 and 2 were analyzed as compared to the No-Build Alternative. The evaluation was conducted for a selected set of resources within certain temporal and spatial boundaries, in reference to historical trends or affects from specific other projects, and that are (for the most part) regulated by various governmental agencies.

Resources Evaluated

Chapter 4 describes the potential direct and indirect encroachment-alteration effects of the South Coast Rail project for a broad range of resources, including environmental (e.g., air, water), ecosystems (e.g., biodiversity, wetlands), and human environment (e.g., historical and archaeological resources, economics). Some resources are expected to be little affected by the Build Alternatives; others may be substantively affected positively or negatively, either directly or indirectly. Some resources have experienced substantial historical impact from other projects or human activity, may experience substantial future impact from other projects or activities, or are of specific interest to decision-makers, regulators, and residents of the South Coast region. A cumulative impacts evaluation of certain

resources was also required by the MEPA Certificate on the ENF. The cumulative impacts evaluation focuses on air quality, biodiversity, economy, land use, protected open space, threatened and endangered species, water quality, and wetlands. Other resources evaluated in Chapter 4 did not meet the selection criteria, are expected to be little affected by the Build Alternatives, and/or do not hold specific interest to stakeholders.

Temporal and Spatial Boundaries

The cumulative impacts analysis defines a time frame and geographic range for the evaluation, and takes into account changes from other projects within this time frame that contribute to cumulative impacts on the resources listed above. Historical impacts have been evaluated for two time periods:

- For most resources, prior changes have been evaluated for the period 1990 to 2008. The year 1990 was selected as the starting date because this is a prior census year, it was in the midst of a period of economic downturn, and it establishes a reasonable baseline condition.

- Some resources have been evaluated over a longer time period where useful data are available. For example, prior impacts to wetlands have been evaluated to 1983, the year that the Massachusetts Wetlands Protection Act (WPA) regulations were established. MassAudubon has published a series of reports documenting changes in land use from 1981.

Current impacts have been evaluated based on 2008/2009 conditions, taking into consideration publication delays for the availability of the most recent data. Future impacts have been evaluated to 2035, the horizon year of the South Coast Rail project.

Spatial boundaries for the analyses varied by resource according to the specific characteristics of the resource, regulatory jurisdictions, and the availability of meaningful data.

- **Land Use**—Land use was evaluated at the local (municipal) and regional levels.

- **Air Quality**—The air quality of the South Coast region is strongly influenced by predominant winds from the southwest and west, bringing air pollutants from upwind states Connecticut, Rhode Island, and New York.[17] Based on regulatory agency jurisdictions and reporting conventions, the three counties within the South Coast Rail study area (Bristol, Norfolk, and Plymouth) are considered to constitute the airshed.

- **Biodiversity**—Biodiversity was evaluated at the ecosystem level (the Bristol Lowlands Ecoregion), considering the biotic communities present in the South Coast region but using the geographic boundaries of the 31 South Coast communities.

- **Economy**—The economy was evaluated at three levels: local (municipal), regional (South Coast Rail study area), and state.

- **Protected Open Space**—Protected open space was evaluated at the local and regional levels.

[17] DEP. 2008. *Final Massachusetts State Implementation Plan to Demonstrate Attainment of the National Ambient Air Quality Standard for Ozone*. Commonwealth of Massachusetts, Executive Office of Energy and Environmental Affairs, Department of Environmental Protection: Boston.

- **Threatened and Endangered Species**—Threatened and endangered species were evaluated at the ecosystem level, but also considering the range of each identified species.
- **Water Quality**—This resource was evaluated at the watershed level.
- **Wetlands**—Wetlands were evaluated at the watershed level when useful data were available. State or regional data were used for historical perspective.

Trends and Reasonably Foreseeable Future Actions

The analysis used readily available data sources for past and future changes, including the MassAudubon *Losing Ground* report series, EEA data and publications, MassDEP wetland change mapping, federal and state agency major permit applications, and other readily available resources. For each resource, the analysis took into consideration:

- Past changes to the selected resources that resulted from development trends or major projects within the study area such as:
  - Fall River Airport closure,
  - Amtrak electrification,
  - New Bedford Wastewater Treatment Plant remediation,
  - Freetown industrial development, and
  - Great Woods development.
- Future changes to the selected resources from anticipated growth based on historic or recent trends, or specific projects, including all reasonably foreseeable projects (i.e., those that are undergoing or have completed major environmental permitting actions or MEPA and/or NEPA reviews), such as:
  - Fall River Executive Park,
  - Route 24 Exit 8A,
  - New Bedford Airport safety improvements,
  - Mashpee Wampanoag Casino, and
  - Other proposed developments.

Regional transportation planning was taken into consideration to the greatest extent possible. The most current regional plan covers the period from 2013 to 2016, and is mostly composed of road and bridge resurfacing and reconditioning projects.[18]

[18] Southeastern Massachusetts Metropolitan Planning Organization. 2009. *FFY 2013-2016 Transportation Improvement Program*. Prepared by the Southeastern Regional Planning and Economic Development District: Taunton, MA.

None of the projects in the plan include new road construction. Although several are identified as congestion relief projects, and specifically reference air quality improvements, quantified impacts to the resources evaluated in this cumulative impacts analysis are not provided. Some projects, identified as "congressional earmarks waiting for project approval and full funding" are also listed, and include projects such as Route 79 Improvements in Fall River and highway interchange and freight rail improvements throughout the South Coast region. It also identifies the relocation of Route 79 in Fall River to create a 4-land urban boulevard with a landscaped median and improved access to developable areas along the waterfront. Similar improvements are identified for Route 18 in New Bedford. Potential impacts associated with these projects are incorporated in the general resource trends described in the cumulative impact assessment.

Although not a "reasonably foreseeable future action" in the traditional sense of cumulative impacts analysis, the possible effects of climate change on resources such as biodiversity, threatened and endangered species, and wetlands has been taken into consideration to the extent possible.

The cumulative impacts evaluation analyzes the past and future changes to the selected resources from development trends and other specific projects within the resource-specific study areas, together with the added impacts of the South Coast Rail alternatives for each alternative and for the two scenarios.

Federal, state, or local governmental agencies regulate most of the resources evaluated for cumulative impacts. The regulatory programs drive many of the trends for improving resource values (e.g., air quality, water quality, and wetlands area) and are therefore important in determining resource impacts of the South Coast Rail and other regional projects. Regulatory programs typically prohibit impacts except as authorized by a permit, are charged with reviewing permit applications, and, generally, only authorize activities that provide the least impact to the resource while still meeting the proposed project's purpose and need. For this cumulative impacts evaluation, existing permitted facilities and proposed actions indicate the current and likely future impacts to the resources.

The agencies responsible for administering these programs are typically charged with managing the resources on a project-by-project basis but in the context of the common good. For example, the federal government has a "no net loss" policy on wetlands; project proponents seeking permits to fill wetland areas are commonly required to offset losses by replacing filled wetlands at a negotiated ratio, such as 2:1 or 3:1. These replacement ratios recognize the inherent unpredictability in creating or restoring replacement wetlands that offset the wetland functions from the project-specific loss, as well as the necessary passage of time between establishing adequate wetland hydrology, and succession to vegetative stability and ultimately functional maturity. This passage of time is particularly lengthy for forested wetlands. Thus, certain regulated resources can experience improvements, rather than degradations, over time.

5.3 DESCRIPTION OF IMPACT SCENARIOS

This section describes the three scenarios evaluated in this chapter: the No-Build Alternative and Scenarios 1 and 2 under the Build Alternatives. Tables 5.3-1 and 5.3-2 present the results of the allocation of induced households and jobs to the municipal level. These results are presented in Figures 5-3 through 5-7. This model was created as part of a theoretical exercise to demonstrate how development patterns could be shifted if the Commonwealth and local municipalities work together to further the goals of the Corridor Plan, in conjunction with local support in the form of zoning and permitting changes.

5.3.1 No-Build (Enhanced Bus) Alternative

This alternative assumes that growth in the South Coast region by 2035 occurs as projected by the three RPAs. These growth projections were developed in 2010 and are based on U.S. Census Bureau data, state requirements, economic trends, and local circumstances. The No-Build Alternative projects that the study area would gain 75,212 households by 2035, with the largest increases in Fall River (7,236), New Bedford (5,290), and Taunton (5,062). The smallest amount of household growth is projected for Marion (285) and Somerset (678).

Under the No-Build Alternative, significant job growth would be experienced throughout the South Coast region and is projected to be greatest in Dartmouth (5,191), Foxborough (4,558), Taunton (4,153), and Canton (3,369), among numerous others that are anticipated to increase their employment base by between 1,800 and 3,340 (Table 5.3-2). However, some municipalities are projected to experience a decrease in their employment base, most significantly in Attleboro (-2,751) and Fall River (-1,518). Overall, municipalities in the South Coast region are projected to add 37,864 new jobs by 2035.

5.3.2 Scenario 1 (Future Growth Scenario without Smart Growth)

Scenario 1 considers baseline growth of the No-Build Alternative plus induced growth from the Build Alternatives. It assumes that no additional smart growth measures would be implemented other than those already incorporated into municipal zoning or state planning.

Residential growth that would be introduced to the South Coast region as a result of the Build Alternatives under Scenario 1 is projected to total 2,804 households. The vast majority of these new households would be located in just a few municipalities: Fall River (533); New Bedford (449); Fairhaven (361); and Westport (205). All other municipalities in the South Coast region are projected to increase by less than 120 households with four communities anticipated to introduce fewer than 10 new households over the No-Build Alternative (Table 5.3-1).

Under Scenario 1, the Build Alternatives are projected to introduce or help retain 1,341 jobs in the South Coast region (Table 5.3-2). Some municipalities such as Attleboro, Fall River, and Fairhaven are projected to decrease their employment base by 2035 over the No-Build Alternative. However, under Scenario 1 of the Build Alternatives, it has been projected that approximately 257 jobs would be retained over the No-Build Alternative. Easton, New Bedford, and Taunton are projected to introduce an additional 137 to 147 new jobs under Scenario 1 of the Build Alternatives over the No-Build Alternative by 2035. The majority of municipalities in the South Coast region are projected to experience a change of less than 40 jobs over the No-Build Alternative.

5.3.3 Scenario 2 (Future Growth Scenario with Smart Growth)

Under Scenario 2, the distribution of the growth (induced and baseline) would shift to be concentrated in the PDAs. Induced growth would be concentrated around Foxborough (749), Fall River (393), New Bedford (334), and Bridgewater (265). Foxborough, Bridgewater, and Attleboro are projected to experience significant growth over the No-Build Alternative and Scenario 1 (Table 5.3-1). The Smart Growth scenario would shift growth (induced and baseline) out of rural communities and ten South Coast region municipalities are projected to experience negative household growth under Scenario 2 of the Build Alternatives. The most significant decline is projected for Westport with a decrease of 230 households by 2035. In total, projections indicate an increase of 2,802 households over the No-Build Alternative, slightly less than under Scenario 1.

Total	75,212	78,016	2,804	78,014	2,802

Source: MAPC, OCPC, SRPEDD.

Projections indicate that approximately 1,339 new jobs would be introduced to South Coast region municipalities under Scenario 2. The vast majority of induced growth job would be concentrated in Foxborough which is projected to increase its employment base by 1,134 over the No-Build Alternative and 1,074 over Scenario 1 of the Build Alternatives. More than half of South Coast region municipalities are projected to lose some of their employment base by 2035 over the No-Build Alternative. However, projections indicate a decrease of between 15 and 113 jobs (Table 5.3-2).

5.3.4 Indirect Effects

This section describes potential environmental impacts that may result under the No-Build and Build Alternatives. This analysis presents a hypothetical comparison of the potential impacts and benefits of the South Coast Rail project. The metrics identified in this section are not anticipated to be exact predictions of indirect effects, but are intended to enable informed comparison and contrast between and among project alternatives.

Potential impacts are relatively similar under the No-Build Alternative and Scenario 1 of the Build Alternatives. Both generally assume that development would continue in a fashion similar to existing conditions and/or in accordance with municipal goals. However, smart growth measures would not be implemented. The low and high scenarios of Scenario 2 under the Build Alternatives assume that a certain amount of smart growth would be implemented to help contain sprawl and impacts to natural resources. Under the low and high scenarios, potential adverse environmental impacts from land development would be less than under the No-Build Alternative or Scenario 1.

Table 5.3-2 Projected Total Job Growth by Community (2035)

5.3.4.1 Land Use

Future development is anticipated to convert undeveloped land to developed areas, including residential, retail, commercial and industrial uses. This analysis evaluates the loss of undeveloped land that would occur by 2035 based on the projected increase in households, using the metrics identified in Table 5.2-2. Commercial, retail, and other land use types are not considered in the analysis. Table 5.3-3 presents the total number of acres that would be developed under the No-Build and Build Alternatives. Appendix 5.3-A identifies land use impacts in study area municipalities under the No-Build and Build Alternatives.

Table 5.3-3 Land Use Impacts by 2035 (Acres of Loss)

Alternative	Scenario 1	Scenario 2 (low)	Scenario 2 (high)
No-Build	38,892	38,892	38,892
Stoughton and Whittenton	40,184	31,631	27,995
Change from No-Build	+1,292	-7,261	-10,897

Municipalities across the South Coast region have different zoning regulations in place that dictate the density of future development. For example, Lakeville zoning regulations require an average of 1.23 acres per household while Canton requires only 0.14 acre per household. As a result, municipalities that are projected to increase the most significantly may require less land than municipalities where less development is anticipated. The low and high scenarios under Scenario 2 assume that growth would be concentrated around station areas and central business districts to support smart growth principles.

No-Build Alternative

The No-Build Alternative is anticipated to result in the loss of 38,892 acres of land for new residential development. The largest losses would occur in Westport (2,325), Taunton (2,278), Middleborough (2,184), and Dartmouth (2,119) while the smallest losses would occur in Marion (168), Somerset (271), and Canton (371). Twelve of the 35 municipalities in the study area would require between 1,000 and 2,000 acres to support projected residential development under the No-Build Alternative.

Scenario 1

Projected residential development under Scenario 1 is projected to require an additional 1,292 acres over the No-Build Alternative for a total of 40,184 acres. Similar to the No-Build Alternative, a significant share of the necessary land would be located in Dartmouth, Middleborough, Taunton, and Westport. Other municipalities that would now require more than 2,000 acres to support projected development under Scenario 1 but not the No-Build Alternative include Portsmouth, RI (2,038) and Rehoboth (2,023). Nineteen municipalities in the study area would require less than 1,000 acres to support projected residential development by 2035. Marion and Somerset would both require less than 300 acres to support projected residential growth.

Scenario 2

Under the low scenario, approximately 31,631 acres would be required to support projected residential development by 2035, a decrease of 7,261 acres over the No-Build Alternative. Twenty-three study area municipalities would require less than 1,000 acres to support projected residential growth. The six

municipalities that would require more than 2,000 acres to support projected residential development under the No-Build Alternative and Scenario 1 would require less than 2,000 acres under the low scenario of Scenario 2.

A total of 25 study area municipalities would require less than 1,000 acres to support projected residential development should smart growth measures be implemented to their fullest. A total of 27,995 acres would be needed to support projected residential development in 2035, a decrease of almost 11,000 acres from the No-Build Alternative and 3,636 acres from the low scenario of Scenario 2.

5.3.4.2 Forest Land

Forest land forms a major element of the South Coast region landscape and provides species habitat, recreation opportunities, and environmental benefits such as carbon sequestration. Forest land, unless protected by restrictions, is particularly vulnerable to development. Table 5.3-4 provides a summary of the total anticipated conversion of forest land to developed land by 2035 in the South Coast study area municipalities to help support projected residential development.

Land area that would be developed under the No-Build Alternative and Scenario 1 of the Build Alternatives assumes that current zoning regulations would continue without the implementation of smart growth measures. As a result, more forest land would need to be developed to help support projected residential growth than would be necessary under Scenario 2 which focuses on concentrated development based on smart growth principles. Appendix 5.3-A identifies forest land impacts in study area municipalities under the No-Build and Build Alternatives.

Table 5.3-4 Forest Land Impacts by 2035 (Acres of Loss)

Alternative	Scenario 1	Scenario 2 (low)	Scenario 2 (high)
No-Build	**19,965**	**19,965**	**19,965**
Stoughton and Whittenton	**20,584**	**16,169**	**14,403**
Change from No-Build	**619**	**-3,796**	**-5,562**

No-Build Alternative

The No-Build Alternative is anticipated to result in the loss of 19,965 acres of forest land to support projected residential development in study area municipalities. Four municipalities would experience a loss of more than 1,000 acres of forest land: Taunton (1,367); Middleborough (1,252); Dartmouth (1,074); and Westport (1,060). All other study area municipalities would require less than 900 acres of forest land to be converted to support projected residential development by 2035. The least amount of forest land to be converted for residential use would be in Marion (134) and Somerset (81).

Scenario 1

Under Scenario 1, approximately 20,584 acres of forest land would be converted to support projected residential development across study area municipalities, 619 more acres than under the No-Build Alternative. The same four municipalities as identified in the No-Build Alternative would require the conversion of more than 1,000 acres to support projected residential development in 2035. Fourteen study area municipalities would require the conversion of less than 500 acres of forest land to support projected residential development. Somerset and Canton would both require less than 200 acres of forest land.

Scenario 2

Under the low scenario, approximately 16,169 acres of forest land would be converted to support projected residential development across study area municipalities, a decrease of 4,415 acres over Scenario 1 and 3,796 acres over the No-Build Alternative. Only two municipalities would require the conversion of more than 1,000 acres of forest land to support projected residential development: Middleborough (1,010) and Taunton (1,095). Nine study area municipalities would require the conversion of less than 300 acres of forest land to support projected residential development.

Under the high scenario, no study area municipalities would require the conversion of more than 1,000 acres of forest land to support projected residential development by 2035. Eleven study area municipalities would experience the conversion of less than 300 acres to support such development, two more municipalities than under the low scenario. Under this scenario, which assumes that smart growth principles would be implemented to the greatest extent possible, approximately 5,562 acres less than under the No-Build Alternative and 6,181 acres less than under Scenario 1 of forest land would be converted to support projected residential development across the South Coast region.

5.3.4.3 Farmland

Farmland is a specific land use type that is of concern in the predominantly rural, agricultural communities of the South Coast region. Land that is held for farmland purposes provides economic benefits and a certain quality of life for people involved in farming activities. Farmland, unless protected by restrictions, is particularly vulnerable to development. Table 5.3-5 provides a summary of the total anticipated conversion of farmland to developed land by 2035 in study area municipalities to help support projected residential development. Appendix 5.3-A identifies farmland impacts in study area municipalities under the No-Build Alternative as well as Scenarios 1 and 2 of the Build Alternatives.

Table 5.3-5 Farmland Impacts by 2035 (Acres of Loss)

Alternative	Scenario 1	Scenario 2 (low)	Scenario 2 (high)
No-Build	9,907	9,907	9,907
Stoughton & Whittenton	10,249	7,903	7,142
Change from No-Build	342	-2,004	-2,765

No-Build Alternative

The No-Build Alternative is anticipated to result in the loss of 9,907 acres of farmland for new residential development. The largest losses would occur in Westport (1,060), Rehoboth (745), Middleborough (670), Portsmouth, RI (668), and Dartmouth (667). Twelve study area municipalities would experience the loss of less than 100 acres of farmland to support projected residential development.

Scenario 1

The loss farmland across the South Coast region to support projected residential development in 2035 under Scenario 1 would be similar to that experienced under the No-Build Alternative. Under the "business as usual" scenario, an additional 342 acres of farmland over the No-Build Alternative would be necessary to support projected residential development.

Scenario 2

Under the low scenario, approximately 2,000 fewer farmland acres would be converted to support projected residential development by 2035 than under the No-Build Alternative. A total of approximately 7,903 farmland acres would be converted for residential use. Twelve study area municipalities would require the conversion of less than 100 farmland acres to support this development. Land conversion in seven municipalities would represent the vast majority of converted farmland; four of which are located in Rhode Island.

Of all project alternatives, the high scenario would require the least amount of farmland to support projected residential development. Should smart growth measures be implemented to the greatest extent possible, as identified in the Corridor Plan, approximately 7,142 farmland acres would be converted to support projected residential growth. This is approximately 761 and 3,107 fewer farmland acres than under the low scenario and Scenario 1.

5.3.4.4 Wetlands

Although wetlands are stringently protected under local, state, and federal laws and regulations, these programs allow wetlands to be altered under certain circumstances, if proponents comply with relevant performance standards. Generally, small losses of wetlands are permissible if there are no practicable alternatives and compensatory mitigation is provided. This analysis assumes that there would be, on average, a small amount of direct wetland alteration for each new household; indirect impacts to wetlands that result from development and could possibly degrade their functions and values were not estimated.

USACE and USEPA have a policy of “no net loss” of wetland functions and values. Accordingly, this analysis assumes that projected wetland losses would be permittable and unavoidable consequences of secondary developments resulting from the South Coast Rail project, and that compensatory mitigation would be required and implemented to offset those wetland losses.

Table 5.3-6 provides a summary of the total anticipated loss of wetlands as a result of residential development by 2035. Appendix 5.3-A identifies wetland impacts in study area municipalities under the No-Build and Build Alternatives.

Table 5.3-6 Direct Wetland Impacts by 2035 (Acres of Loss)

Alternative	Scenario 1	Scenario 2 (low)	Scenario 2 (high)
No-Build	12.8	12.8	12.8
Stoughton and Whittenton	13.3	10.1	9.4
Change from No-Build	0.5	-2.7	-3.4

No-Build Alternative

The No-Build Alternative is anticipated to result in the loss of 12.8 wetlands acres to support new residential development. Only Fall River would experience the loss of more than one wetland acre. Twenty-eight study area municipalities are anticipated to lose 0.50 acre or less of wetland acres to support projected residential development by 2035.

Scenario 1

Under Scenario 1, an additional 0.50 wetland acre would be necessary to help support projected residential development over the No-Build Alternative. Because of the number of municipalities in the study area and small change from the No-Build to Scenario 1 of the Build Alternatives in terms of the acreage of wetlands necessary, the typical increase is significantly less than 0.1 acre. An additional 0.9 acre would be necessary to support projected residential development in Fall River by 2035.

Scenario 2

The low scenario would require approximately 2.7 fewer wetland acres to support projected residential development by 2035 than the No-Build Alternative. The implementation of smart growth measures would reduce wetland impacts by approximately 3.2 acres over Scenario 1, where development would continue as under existing conditions. Wetland impacts in Fall River would be less than 1 acre under the low scenario and required acreage would also decrease in all other study area municipalities.

Should smart growth measures be implemented to the fullest extent possible as identified in the Corridor Plan, wetland impacts would decrease to 9.4 acres, approximately 3.4 acres and 3.9 acres less than under the No-Build Alternative and low scenario, respectively. Many study area municipalities would experience less than 0.2 acre of wetland impacts should residential development be concentrated in PDAs and away from PPAs.

5.3.4.5 Biodiversity

New development is anticipated to result in the loss of biological diversity within the South Coast region by reducing the abundance of plants and animals. Development may affect plants and animals in both terrestrial and aquatic habitats through the direct loss of habitat, the creation of barriers to the movement of organisms, the reduction of habitat quality, and the reduction in the size of available habitats. The net results of these changes may reduce the size of populations, eliminate some populations, or potentially eliminate some species. These effects are directly correlated with the loss of natural undeveloped land, but also a result of new infrastructure (roads, utilities) required to support new development.

Table 5.3-7 provides a summary of the total biodiversity impacts anticipated by 2035 under each project alternative. Appendix 5.3-A identifies biodiversity impacts in study area municipalities under the No-Build and Build Alternatives.

Table 5.3-7 Biodiversity Impacts by 2035 (Acres with Decreased Value)

Alternative	Scenario 1	Scenario 2 (low)	Scenario 2 (high)
No-Build	116,675	116,675	116,675
Stoughton and Whittenton	120,551	74,967	58,706
Change from No-Build	3,876	-41,708	-57,969

No-Build Alternative

The No-Build Alternative is anticipated to affect biodiversity according to a 3:1 ratio. For every 1 acre of undeveloped land that is converted for development, there will be an impact on the biodiversity of an

additional 3 acres of land.[19] The greatest impacts on biodiversity would occur in communities where there is projected to be large amounts of new residential development. The No-Build Alternative would reduce the biodiversity value of an estimated 116,675 acres of land within the study area. Only Marion and Somerset are anticipated to have impacts that are less than 1,000 acres. Should residential development occur as projected, six municipalities would experience biodiversity impacts of between 5,900 and 7,000 acres: Dartmouth; Middleborough; Rehoboth; Taunton; Westport; and Portsmouth, Rhode Island.

Scenario 1

Under Scenario 1, the ratio of biodiversity impacts are anticipated to be the same as under the No-Build Alternative. Biodiversity impacts under Scenario 1 would increase by almost 4,000 acres than under the No-Build Alternative. Should residential development occur as anticipated, approximately 120,551 acres would experience biodiversity impacts.

Scenario 2

The low scenario assumes that the biodiversity impact ratio would decrease to 2.37:1 from the 3:1 ratio under the No-Build Alternative and Scenario 1 of the Build Alternatives. Under the low scenario, the implementation of smart growth measures would decrease biodiversity impacts by almost 42,000 acres over the No-Build Alternative. All study area municipalities would experience biodiversity impacts of less than 4,500 acres, a significant decrease than under the No-Build Alternative and Scenario 1. Six municipalities would experience biodiversity impacts of less than 1,000 acres, three of which are located closer to Boston and already experience significant development.

Assuming that smart growth measures are implemented to the greatest extent possible as identified in the Corridor Plan, the biodiversity impact ratio would decrease to 2.10:1. As a result, total biodiversity impacts would decrease even further than under the low scenario. Under the high scenario, approximately 58,706 acres would experience biodiversity impacts by 2035. This is slightly less than 58,000 acres less than under the No-Build Alternative. The high scenario would impact slightly less than 16,000 acres than under the low scenario. Significant reductions in biodiversity impacts would occur in municipalities where PDAs exist and/or TOD plans or other smart growth measures are in place or anticipated, such as Taunton, Stoughton, Rehoboth, Westport, and Portsmouth, Rhode Island.

5.3.4.6 Infrastructure

New development would place increased demand on municipal infrastructure, particularly water and sewer services. This section evaluates the increase demand for water resulting from projected residential growth in the South Coast region. Many study area municipalities rely on groundwater sources and impose water restrictions under most summer conditions due to limited supply. As a result, new development has the potential to place significant demand on water resources if appropriate measures are not put in place. Table 5.3-8 provides a summary of the change in water demand anticipated by 2035 under the No-Build and Build Alternatives.

[19] DeNormandie, J. (2009). *Losing Ground: Beyond the Footprint*. Lincoln, MA. Massachusetts Audubon Society.

Table 5.3-8 Water Demand by 2035 (Gallons per Household)

Alternative	Scenario 1	Scenario 2*
No-Build	12,221,993	12,221,993
Stoughton and Whittenton	12,677,600	11,029,902
Change from No-Build	455,607	-1,192,091

Note: Assumes that water demand will be almost the same under the low and high scenarios because the difference between the two is only two households.

No-Build Alternative

The No-Build Alternative is anticipated to continue current patterns of household water use. It assumes the current trend of 65 gallons per person per day would continue. Assuming there are 2.5 people per household, the average household's water consumption would be approximately 162.5 gallons per day (gpd). Should development continue as projected, water consumption under the No-Build Alternative is anticipated to total approximately 12,221,993 gpd by 2035. The more significant impacts on water demand will be borne by communities projected to increase notably over the next 20 years. New residential development is projected to be greatest in Fall River, New Bedford, and Taunton, therefore these communities would place the largest increased demand on water resources.

Scenario 1

Scenario 1 assumes the same water consumption patterns as under the No-Build Alternative. As a result, increased household development that is projected as a result of the Build Alternatives would place additional demand on water resources. The introduction of an additional 2,804 households would increase water demand by approximately 455,600 gpd over the No-Build Alternative by 2035.

Scenario 2

Under Scenario 2, smart growth measures for small lots, clustered single-family housing, or multifamily housing developments would have beneficial effects on water demand because there would be smaller lawns to water and fewer paved surfaces to keep clean. It is estimated that the average household's water consumption under this scenario would be approximately 141.4 gpd. Water demand under this scenario is anticipated to decrease by approximately 1,192,091 gpd and 1,647,698 gpd over Scenario 1 of the Build Alternatives and the No-Build Alternative, respectively. This represents a decrease of 13.0 percent and 9.9 percent.

5.3.4.7 Traffic

Future regional growth is anticipated to result in increased VMT. CTPS conducted regional travel demand modeling using the No-Build and Build Alternatives as inputs to the model. The model, which is based on the traditional four-step urban transportation planning process, uses 2010 as the base year and examines travel patterns on an average weekday for four time periods. It takes into consideration data on service frequency, routing, travel time, transit parking availability, and fares of all transit services as well as connectivity, length, speed, capacity, and tolls, among others associated with the roadway network. Traffic forecasts were then prepared based on the population and employment projections under the No-Build and Build Alternatives as presented in Tables 5.3-1 and 5.3-2. Table 5.3-9 provides a summary of the projected increase in vehicle miles and hours traveled under the No-Build and Build Alternatives in 2035.

Table 5.3-9 Vehicle Miles and Hours Traveled by 2035 (per day)

	Vehicle Miles Travelled (VMT)		Vehicle Hours Travelled (VHT)	
Alternative	Total	Difference from No-Build	Total	Difference from No-Build
No-Build	118,894,000		3,956,500	
Stoughton Electric	118,641,800	-252,200	3,944,200	-12,300
Whittenton Electric	118,696,500	-197,500	3,947,300	-9,200
Stoughton Diesel	118,654,800	-239,200	3,944,700	-11,800
Whittenton Diesel	118,708,500	-185,500	3,947,700	-8,800

No-Build Alternative

Under the No-Build Alternative, the South Coast region would experience substantial population and employment growth. This growth would result in increased VMT and VHT. Daily VMT in the region is projected to total approximately 11.89 million while daily VHT would increase to just under 4 million hours.

Stoughton Alternative

Under the Stoughton Electric Alternative, daily VMT would decrease by approximately 252,200 and 54,700 over the No-Build and Whittenton Alternatives, respectively. The Stoughton Electric Alternative would also reduce VHT the most significantly of the project alternatives. The model estimates that approximately 12,300 hours would be saved daily over the No-Build Alternative. Daily VHT would total approximately 3.94 million hours. Stoughton Diesel effects on traffic would be slightly less than Stoughton Electric (239,200 reduction in VMT and 11,800 reduction in VHT).

Whittenton Alternative

The Whittenton Electric Alternative would result in fewer VMT and VHT than the No-Build Alternative but not result in savings as significant as under the Stoughton Electric Alternative. A daily reduction of approximately 197,500 VMT would result from the operation of the Whittenton Electric Alternative over the No-Build Alternative. Daily VHT savings would be approximately 9,200 less than the No-Build Alternative, 3,100 fewer hours than under the Stoughton Electric Alternative. The model identifies longer travel times from New Bedford and Fall River up through Taunton as a cause of reduced demand at these stations. Vehicle miles may also increase as a result of people willing to bypass the slower segment of the Whittenton Alternative in Taunton in order to pick up the train north of the delay during the morning peak inbound commute period.

Whittenton Diesel effects on traffic would be slightly less than Whittenton Electric (185,500 reduction in VMT and 8,800 reduction in VHT).

5.3.4.8 Greenhouse Gas Emissions

Future regional growth is anticipated to result in increased emissions of regulated air quality pollutants from mobile and stationary sources, as well as increased GHG emissions (primarily CO_2). This analysis evaluates GHG emissions based on an average emission factor of 11.83 tons per year (tpy) per household and change in VMT.

GHG Emissions by Household

Although dispersed residential development under Scenario 1 can be contrasted with more compact, clustered development patterns anticipated under Scenario 2, emission factors specifically applicable to smart growth-style development were not available. This analysis therefore compares GHG emissions that may be expected from overall household growth, with the general assumption that there would be lower GHG emissions under Scenario 2 than under Scenario 1.

Regional GHG emissions would increase and reduced sequestration capacities would be experienced as undeveloped forests are cleared to accommodate new residential development with and without the South Coast Rail project. Various studies have attempted to quantify the role of forests in helping to sequester carbon from the atmosphere, but the analysis is complex and depends on multiple variables, many of which are poorly understood. The carbon sequestration capacity of individual tree species, the age of forests, the volume of trees cut down, and soil disturbance are a few examples of multiple factors that would affect carbon emissions in a certain area. Because it is very complex and not well understood, quantitative analysis of carbon sequestration was not undertaken for the South Coast Rail alternatives.

This analysis evaluates the increase in GHG emissions from residential sources that would occur by 2035 based on the anticipated increase in households, using the metrics identified in Table 5.1-2. A summary of this information is presented in Table 5.3-10 and described in greater detail in Appendix 5.3-A.

Table 5.3-10 Greenhouse Gas Emissions from Residential Development by 2035[1]

Alternative	Scenario 1	Scenario 2
No-Build	889,761	n/a
Stoughton and Whittenton	922,929	<922,929
Change from No-Build	33,168	<33,168

1 (CO_2 tons/year)

No-Build Alternative

For stationary sources of GHG emissions, current patterns of residential housing construction are expected to continue under the No-Build Alternative. Using the eQUEST model on a typical 2,000-square-foot (sf) house, estimated household GHG emissions are approximately 11.83 tpy. The No-Build Alternative is anticipated to result in an increase of 889,761 tpy of GHG emissions between 2000 and 2035. The projected increase in residential development in in Fall River, New Bedford, and Taunton would result in those communities having the greatest stationary source GHG emissions.

Scenario 1

Under Scenario 1, the Stoughton and Whittenton Alternatives are anticipated to indirectly result in an increase of 33,168 tpy in stationary source GHG emissions by 2035 over the No-Build Alternative, an increase of 4 percent. The largest GHG emissions would occur in Fall River, New Bedford, and Taunton.

Scenario 2

To estimate the change in stationary source GHG emissions from residential development, the eQUEST model was given an input of a prospective 1,500 sf home, one that might be found in a small lot or

multifamily housing development that is more likely to be introduced to study area municipalities should smart growth measures be in place. The model calculated the household GHG emissions to remain at 11.83 tpy despite the reduction in house size. As a result, the total stationary source GHG emissions are same for both scenarios.

GHG Emissions by VMT

This section provides an overview of estimated CO_2 emissions in 2035 that would result under each alternative from the change in VMT. Unlike the stationary source emission analysis above, this information is presented by alternative and for Scenario 1 only. As demonstrated in Table 5.3-11, the Stoughton Electric Alternative would result in the greatest reduction in CO_2 emissions over the No-Build Alternative. The operation of this alternative would result in the decrease of approximately 52,425 tons of CO_2 annually. The Whittenton Electric Alternative would result in a decrease of approximately 41,055 tons of CO_2 in comparison to the No-Build Alternative. The Stoughton Diesel Alternative would result in greater CO_2 reductions than the Whittenton Electric Alternative, but slightly less than the Stoughton Electric Alternative. The Whittenton Diesel would have the smallest effect on CO_2 emissions from automobile travel under Scenario 1. Although not quantified, the regional VMT and CO_2 emissions under Scenario 2 would be slightly less than the numbers presented for Scenario 1 (see discussion below for further assessment of Scenario 2).

Table 5.3-11 Greenhouse Gas Emissions from Regional Vehicle Miles Travelled by 2035, Scenario 1

	Vehicle Miles Travelled (VMT) (daily)		Carbon Dioxide (CO_2) tons/year	
Alternative	Total	Difference from No-Build	Total	Difference from No-Build
No-Build	118,894,000		24,714,942	
Stoughton Electric	118,641,800	-252,200	24,662,517	-52,425
Whittenton Electric	118,696,500	-197,500	24,673,887	-41,055
Stoughton Diesel	118,654,800	-239,200	24,665,218	-49,724
Whittenton Diesel	118,708,500	-185,500	24,676,380	-38,562

Note: VMT is anticipated to be slightly less under Scenario 2. Numbers reflect auto VMT only.

To provide some basis for comparing the effects of Scenario 1 and Scenario 2, a separate VMT analysis was conducted for the South Coast Rail communities (the regional model analysis includes most of eastern Massachusetts). The analysis used conversion factors (VMT per household per day) unique to each municipality based on projected increases in households. These municipality-specific factors were prepared by MAPC based on an analysis of 16 million Registry of Motor Vehicles inspection records. The per household VMT for each community included in this analysis includes local trips (schools, shopping, and jobs) rather than the long-distance commuting VMT that is evaluated in the regional assessment of the direct transportation effects of each alternative. Table 5.3-12 summarizes the results, with detailed tables with results for each community provided in Appendix 5.3-A.

Under the No-Build Alternative, the South Coast region would experience population growth and corresponding increases in VMT of 4,961,201 per day by 2035. The largest increases are expected in Fall River, Taunton, and Westport.

Table 5.3-12 Greenhouse Gas Emissions Increase from VMT in South Coast Rail Communities[1]

Alternative	Scenario 1	Scenario 2
No-Build	4,961,201	N/A
Stoughton and Whittenton	5,123,749	5,122,664
Change from No-Build	+162,548	+161,463

1 CO_2 tons/year

Under Scenario 1, induced growth would increase VMT by 5,123,749 per day by 2035; an increase of 162,549 more VMT per day than the No-Build Alternative. The largest increases are expected in Fall River, Taunton, and Westport.

Under Scenario 2, implementing Smart Growth measures is anticipated to shift some new development from the PPAs to targeted development areas, and to allow more dense residential and mixed-use development in the PDAs. Scenario 2 is anticipated to increase VMT by 5,122,664 per day by 2035. The largest increases are expected in Fall River, Middleborough, and Taunton. The Stoughton and Whittenton Alternatives under the Smart Growth scenario are anticipated to result in 1,805 less VMT per day than Scenario 1. Relative to the No-Build Alternative, Scenario 2 would increase VMT by 161,464 per day (3 percent).

5.3.4.9 Economic Effects

The economic analysis of the South Coast Rail project as reported in the Corridor Plan and Chapter 4.3, *Socioeconomics*, estimated the overall direct and indirect economic effects on the South Coast region as a result of implementing the Build Alternatives, based on the TREDIS model. Communities across the region can expect to benefit from additional tax revenues from growth, but they should also expect some infrastructure costs for roads, water, and wastewater systems. The following provides a qualitative assessment of potential economic effects associated with the South Coast Rail project.

No-Build Alternative

Under the No-Build Alternative it is projected that an additional 75,212 households and 37,865 jobs would be introduced to the South Coast region by 2035. Municipalities across the region would experience economic benefits in the form of additional property tax revenue, such benefits would be greater in those municipalities where growth is projected to be higher such as Fall River, New Bedford, and Taunton. However, the extent of additional tax revenue that is recognized from new residential development would also depend on municipal property tax rates – a determination that is beyond the scope of this project. Increased employment activity as a result of new residential development and job creation would also result in increased economic benefits, the extent to which would be recognized the most in areas where job growth is highest.

Scenario 1

Under Scenario 1 of the Build Alternatives, household and employment growth would continue as under existing conditions and would not include smart growth measures. An additional 2,804 households and 1,341 jobs are projected to be introduced to the South Coast region over the No-Build Alternative. Municipalities would recognize economic benefits as a result of increased property tax revenues and employment activity. Municipalities with the greatest projected growth and highest tax rates would recognize the greatest economic benefits as a result of such development. Municipalities where the greatest residential growth is projected over the No-Build Alternative include Fairhaven, Fall River, and

New Bedford. Easton, Taunton, and New Bedford are projected to experience the greatest job growth of study area municipalities. However, Scenario 1 would help retain 194 jobs in Fall River, one of the municipalities projected to experience significant job loss by 2035.

Scenario 2

Scenario 2 of the Build Alternatives assumes that smart growth measures would be implemented in accordance with the Corridor Plan and municipal objectives. Growth, both residential and employment, would be concentrated around PDAs and away from environmentally-sensitive areas (PPAs). While overall growth numbers (both residential and employment) is anticipated to occur on a similar scale under both Scenario 1 and Scenario 2, such development would be redistributed across the South Coast region differently than under Scenario 1.

Under Scenario 2, municipalities such as Stoughton, among others are projected to experience notable residential growth over Scenario 1 and the No-Build Alternative. As a result, these municipalities are anticipated to receive more in property taxes than they would under Scenario 1. Other municipalities such as Fall River, New Bedford, Lakeville, Raynham, and Westport, among others are projected to experience less residential development than under either the No-Build Alternative or Scenario 1. As a result, it is anticipated that these municipalities would experience less property tax revenue than under other alternatives.

Job growth is projected to be concentrated in Bridgewater, Easton, and Foxborough as compared to either the No-Build Alternative or Scenario 1. These municipalities, particularly Foxborough, would experience the greatest economic benefit of smart growth measures and increased employment. The majority of other municipalities are projected to experience a slight decrease in their employment base under Scenario 2 as compared to the No-Build Alternative and Scenario 1. Because projected employment loss represents such a small share of overall municipal employment, it is not anticipated that such a decrease would adversely affect tax revenues in a significant fashion as compared to the Bo-Build Alternative.

5.4 CUMULATIVE IMPACTS

This section describes the cumulative impacts of the South Coast Rail project on the following resources: air quality, biodiversity, economy, land use, protected open space, threatened and endangered species, water quality, and wetlands

5.4.1 Land Use

Land use in Massachusetts is directly regulated at the local level, typically through municipal zoning laws and ordinances. Although unique to each municipality, zoning laws commonly designate land usage (into categories such as residential, commercial, industrial, and open space) and development density (for different types of land use such as multi-family or single-family homes, and lot size). Indirect regulation from federal and state agencies derives from policies established by land management agencies responsible for federal- or state-owned property, as well as certain programs such as the federal Wild and Scenic River program (which protects designated waterways) and the state ACEC program. Additionally, traditional environmental media-oriented laws can function as *de facto* land use regulatory programs; new facilities with air emissions or wastewater discharges, for example, may not be permitted in certain locations if the project design cannot meet air quality or water quality standards or requirements.

Managing land use, and in particular motivating a change in land use, may be accomplished by financial or other incentives. Tax increment financing and TDR programs, potential components identified in the Corridor Plan, may be used by the state to motivate local land use change. To that end, the state has assisted each community in identifying PDAs and PPAs that would focus development in certain areas and limit it in others. These programs are intended to limit sprawl – a potential negative indirect effect of the South Coast Rail project.

This section evaluates the cumulative impacts of converting land from a natural state to developed land. Current land use within the South Coast region reflects the historical development of the area. Although much of the land is considered open space (forest, parks, farmland, or otherwise undeveloped land), no areas are completely undisturbed by human activity. Native Americans disturbed the natural environment prior to arrival of Europeans in the 1600s; forest fires were set to clear land and hunt for wildlife.[20] Development by European immigrants included establishing the villages that have grown into the communities currently present. Forests were cut for fuel and construction materials. Old growth forests (defined as having not been logged or disturbed for over 150 years) in the South Coast region are limited to 400 acres of the Acushnet Cedar Swamp, in which old-growth stands of Atlantic white cedar provide about 25 percent of the vegetative cover.[21] The industrial age concentrated development at locations with certain required resources (e.g., Fall River, where river flow powered mills) or convenient for transporting goods (e.g., New Bedford, with a protected harbor for seafaring). Agricultural land use also changed the landscape with forests cleared for crops.

As described in Chapter 4.14, *Biodiversity*, *Wildlife, and Vegetation*, a perspective of recent historical changes in land use is offered by the MassAudubon *Losing Ground* study series. The study was originally published in 1987, with new editions in 1999, 2003, and 2009. Each edition documents broad changes in land use over time. Although the study series provides a state-wide analysis, some aspects are community-specific or can be applied at the regional level.

The 1987 study[22] found that, statewide, open land developed for residential and commercial use between 1981 and 1986 totaled 103,000 acres (20,600 acres per year). The average growth in land development for that period was 2 percent per year. The 1999 study[23] analyzed land development in Massachusetts from 1971 to 1996 and found that the average annual rate of land conversion statewide had decreased from nearly 21,000 acres per year in the mid-1980s to just under 16,000 acres per year in the late 1990s. It further states that developed land has increased from 15.0 percent in 1972 to 23.8 percent in 1996.

Although the 1999 report does not provide community-specific data, the 31 South Coast study area communities in Massachusetts lie within areas characterized as under the greatest development pressure in the period from 1980 to 1996. The six northernmost communities in the South Coast region fell within a middle range of development with 36 to 60 acres developed per square mile of each municipality for that period. The thirteen communities in the central/southern portion varied considerably in newly developed acreage with Mansfield in the highest category of 102 to 169 acres developed per square mile. The twelve communities along the coast generally fell within the lowest ranges of newly developed land with only Fairhaven and Marion reaching the same middle range as the

northern communities. These data suggest the greatest development pressures closest to the Boston metropolitan area, with decreasing development pressure (and some local variation) with increasing distance from Boston.

The 2003 study[24] focused on changes from 1985 to 1999 in forest and agricultural land use to residential and commercial development, and the hidden impacts of development. MassAudubon calculated an average visible (in aerial photographs) conversion of 40 acres per day of which 88 percent was attributable to new residential development.

According to the 2009 study,[25] natural land in 2005 for the 31 South Coast Study area municipalities in Massachusetts totaled 347,263 acres (an average of 11,202 acres per community). In the period from 1999 to 2005, 7,888 acres (2.2 percent of the 1999 total) in those 31 communities had been converted from natural land to developed land. The average annual natural-to-developed land conversion rate in the South Coast region was 1,315 acres. The conversion rate varies by community, generally according to zoning densities.

The Corridor Plan depicts current land uses for the entire South Coast region based on generalized community zoning.[26] Chapter 4.2, *Land Use, Zoning and Public Policy*, provides maps indicating land uses and zoning along each alternative alignment. These figures also show that residential zoning dominates the South Coast region (at varying degrees of density), although much of the land is actually undeveloped (see *Corridor Plan*, Figure 4-5). Concentrated residential, commercial, and industrial use occurs at the larger towns in the region: New Bedford, Fall River, Taunton, Attleboro, Mansfield, Stoughton, and Canton.

Differences in development density are also reflected, to some degree, in a north-to-south direction. The Corridor Plan's characterization of community's urban, suburban, or semi-rural character (see *Corridor Plan*, Figure 4-1) reflects this geographic trend, combined with the concentrated development at selected coastal communities.

Current and foreseeable projects as mentioned above are commonly located within or near the concentrated development of existing communities or along transportation corridors. Many of these projects consist of redevelopment of industrial property, such as the redevelopment of the Fall River Airport as the Fall River Commerce Park. This project generally does not constitute land use changes from undeveloped to developed land as most of the areas were previously disturbed.

One future project with a specific land use change, the proposed Route 24 Access Improvement Project, would convert 16.6 acres of forest (undeveloped) land to transportation use for a new interchange.[27] Numerous additional projects, at varying degrees of planning or speculation, are listed in the Corridor Plan as candidates for PDAs under Scenario 2.[28] Quantifiable land use conversions are not available for

all future projects. As noted in Table 5.4-1, the total area encompassed by the PDAs in the 31 South Coast study area municipalities in Massachusetts is 29,079 acres; it is not known what proportion of that area would be converted from undeveloped to developed land if each project was completed.

Source: Corridor Plan, Figure 6-2 Corridor Map.

Based on the land use impacts presented in Table 5.3-3, approximately 38,892 acres of natural land would be converted to developed land by 2035 under the No-Build Alternative, representing approximately 11.2 percent of the 347,263 acres of natural land present in the South Coast region in

2005. Approximately 308,371 acres of natural land would remain in the South Coast region in 2035 under the No-Build Alternative.

Property acquisitions are used as a convenient indicator of direct land use impacts. The Stoughton Alternative would involve acquisition of 49.8 acres and the Whittenton Alternative would involve acquisition of 39.6 acres of undeveloped land. The greater land acquisition requirements for the Stoughton Alternative are in large part a result of a need to re-acquire the rail right-of-way between Route 138 and Winter Street in Raynham and Longmeadow Road in Taunton, which does not exist under the Whittenton Alternative. In addition to changes in ownership, both alternatives would convert undeveloped land (both in areas currently owned by MassDOT and in new property acquisitions) to transportation use as part of reactivation of rail service to abandoned corridors. Table 5.4-2 shows that the indirect effect on land use under Scenario 1 would be the conversion of 40,184 acres of undeveloped land to developed land, for a combined total of direct and indirect conversion of 40,234 acres for the Stoughton Alternative and 40,223 acres for the Whittenton Alternative. Combining historic trends in land use conversions, recent or reasonably foreseeable future actions, and the varying land conversions that would result from the Stoughton and Whittenton Alternatives, cumulative impacts of the South Coast Rail project to land use in 2035 are presented in Table 5.4-2.

Approximately 308,371 acres of natural land would remain in the South Coast region in 2035 under the No-Build Alternative. Under Scenario 1, approximately 307,029 acres of natural land would remain under the Stoughton Alternative and 307,040 acres would remain under the Whittenton Alternative. The difference between the Build Alternatives is negligible in a regional context and is due to the greater direct impact (land acquisition) requirements for the Stoughton Alternative noted above. However, it is important to note that direct land conversion (reactivation of rail corridors) would not be limited to the areas of property acquisitions (see Chapter 3 for description and mapping of areas where rail service would be reactivated under the Stoughton and Whittenton Alternatives). The additional loss of 1,331 to 1,342 acres from induced growth indirectly resulting from the Stoughton or Whittenton Alternatives plus direct land acquisition impacts under Scenario 1 would represent approximately 0.4 percent of the total natural land area.

Table 5.4-2 Cumulative Impacts to Land Use in 2035 (in acres)

Historical Trends Affecting Land Use	Trends and Current of Future Actions Affecting Land Use	Alternative	Land Use Conversion: Project Direct and Indirect Effects	Natural Land Remaining in 2035	Change from no-Build	% Change from No-Build
Land conversion for agricultural, residential, commercial, and industrial development	Average land conversion of 1,315 acres per year	No-Build	N/A	308,371	N/A	N/A
				Build Alternatives		
				Scenario 1		
		Stoughton	40,234	307,029	-1,342	-3%
		Whittenton	40,223	307,040	-1,331	-3%
				Scenario 2		
		Stoughton	28,005 to 31,681	315,582 to 319,258	-7,213 to -10,889	19% to 28%
		Whittenton	27,994 to 31,670	315,593 to 319,269	-7,232 to -10,898	19% to 28%

Under Scenario 2 low and high implementation of smart growth measures, approximately 315,582 and 319,258 acres of natural land would remain, respectively, for the Stoughton Alternative. For the Whittenton Alternative, 315,593 to 319,269 acres would remain. Approximately 7,213 to 10,898 fewer acres would be lost to development under Scenario 2 than under the No-Build Alternative, a decrease of up to 28 percent. The Build Alternatives would not result in substantial adverse cumulative impacts to land under Scenario 1 and Scenario 2 would substantively slow the rate of land conversion.

5.4.2 Protected Open Space

Publicly owned protected open spaces are regulated by the agency responsible for the property (whether federal, state, or local). Privately owned protected open spaces are not directly regulated by a governmental agency unless a deed restriction (such as a conservation agreement) is attached to the property. At all levels, conversion of publicly or privately owned protected open space to other uses is strongly regulated.

Through a variety of legal vehicles (such as actual ownership or conservation restrictions), public and private entities have protected open space from development throughout the state. In the period from 1999 and 2005, 109,863 acres of open space were newly protected from development.[29] In 2008, an additional 24,104 acres of land were protected by state action[30] and another 54,818 acres were protected in 2009.[31]

Data regarding the total area of recent protections to open space in the South Coast region were not readily available. Using the Commonwealth open space acquisition assumptions, protected open space would expand by 0.7 percent per year (14.7 percent overall), or about 383.7 acres per year (9,976 acres total), resulting in approximately 64,795 acres of protected open space in the South Coast study area municipalities in Massachusetts by 2035.

Under Scenario 1, approximately 64,794 acres of open space would remain under the Stoughton and Whittenton Alternatives. The additional loss of less than 0.66 acre of direct impacts from the Stoughton and Whittenton Electric Alternatives would represent approximately 0.001 percent of the total protected open space area in the South Coast region. Open space impacts for Scenario 2 are unknown but presumably greater than 0.66 acre; however, less open space would be lost to development under Scenario 2 than under the No-Build Alternative or Scenario 1 due to implementation of smart growth measures. The Build Alternatives would not result in substantial adverse cumulative impacts to open space under Scenario 1 and Scenario 2 would slow the rate of land conversion as compared to the No-Build Alternative.

The Corridor Plan identifies 72 PPAs but does not quantify the area of the PPAs nor specifically identify where candidate PPA sites would qualify for protection as public open space status under Article 97 of the Massachusetts Constitution. Although the implementation of smart growth measures of the Corridor Plan would orient growth away from PPAs, new protected open space would not be formally established under Scenario 2. Separate initiatives would be required to designate additional protected open space; however, it is not possible to accurately project the extent of any new protected open space that could be designated. Based on these factors, speculations on increases in protected open

[29] MassAudubon 2003. Losing Ground: At What Cost? (Third Edition of the Losing Ground Series), Changes in Land Use and Their Impact on Habitat, Biodiversity, and Ecosystem Services in Massachusetts. Massachusetts Audubon Society: Lincoln, MA.

space that may result from the establishment of PPAs do not meet the definition of "reasonably foreseeable projects" for a cumulative impacts analysis.

Combining historic trends of increasing protection of open space and the varying effects on protected open space that would result under the South Coast Rail project by 2035 are presented in Table 5.4-3.

Table 5.4-3 Cumulative Impacts to Protected Open Space in 2035 (in acres)

Historical Trends Affecting Open Space	Trends and Current or Future Actions Affecting Protected Open Space	Alternative	Protected Open Space			
			Project Direct and Indirect Effects	Protected Open Space in 2035	Change from No-Build	% Change from No-Build
State commitment to protect open space through acquisition, spending $50M per year	Open space protected at a rate of 383.7 acres per year	No-Build	N/A	64,795	N/A	N/A
		Build Alternatives				
		Scenario 1				
		Stoughton	0.66*	64,794	-0.66	<-1%
		Whittenton	0.66*	64,794	-0.66	<-1%
		Scenario 2				
		Stoughton	>0.66	>64,794	Unknown	Unknown
		Whittenton	>0.66	>64,794	Unknown	Unknown

Note: *0.66 acre for Stoughton and Whittenton Electric Alternatives. Impact is 0.16 acre for the Stoughton and Whittenton Diesel Alternatives.

5.4.3 Wetlands

Wetlands protection is closely related to the surface water quality laws and regulations mentioned above. Specifically, at the federal level, Section 404 of the CWA requires a Department of the Army permit for the discharge of dredged or fill material into waters of the United States, including adjacent wetlands. The Massachusetts WPA and WPA Regulations provide state protection. As mentioned above, a federal "no net loss" policy requires mitigation of wetland impacts. Only one community within the South Coast Rail study area, Westport, has registered wetlands within its boundary and has adopted restriction orders in compliance with the Coastal Wetlands Restriction Act or Inland Wetlands Restriction Act.

Wetlands in Massachusetts are currently protected at both the federal and state level.[32] Regulatory programs implementing the federal CWA, as administered by the Corps, are conducted in compliance with the national policy of "no net loss" of wetlands.[33] At the state level, the regulatory programs implementing the Massachusetts Clean Waters Act and the Massachusetts WPA, administered by MassDEP, provide similar wetlands protection. The USEPA notes that activities in upland areas outside of regulatory control may degrade wetlands quality, if not quantity.

Existing wetlands in the South Coast region reflect the long history of land use change described in Section 5.4.1. Wetland areas in Massachusetts in the 1780s totaled approximately 818,000 acres,

[32] Only one community (Westport) in the South Coast region has adopted wetland restriction orders in compliance with state laws, but all of the communities could do so.

[33] White House Office on Environmental Policy. 1993. Protecting America's Wetlands: A Fair, Flexible, and Effective Approach. Washington, DC.

representing about 15.5 percent of the state's 5,284,480 acres.[34] By the 1980s, the total wetland area decreased to approximately 588,486 acres, representing 11.1 percent of the total area of the state and a 28-percent decrease over the 200-year period. In 1992, this had further decreased to only 6 to 7 percent of total Commonwealth land.[35]

Wetlands loss rates, both in terms of the numbers of acres lost annually and percentage of total wetland area, have varied substantively over time. Losses can be attributed to several different types of conversions, which have also changed over time. The loss of 229,514 acres of wetlands in 200 years averaged nearly 1,150 acres per year, a 0.14 percent annual loss rate. In 1978, the U.S. Soil Conservation Service[36] estimated Massachusetts' annual wetland loss rate at 0.4 percent, and attributed the losses primarily to urbanization. Historically, the state has lost between 58 and 64 percent of its wetlands from conversion to agriculture, road construction, and other building projects.[37]

Recently, MassDEP initiated a wetlands loss mapping project, which includes a review of recent historical and current aerial photographs to more precisely identify wetland losses by comparing aerial photographs taken in 1990, 2001, and 2005. These losses include both legal[38] (permitted) and illegal (unpermitted) wetland loss. Wetlands lost by a permitted activity may have been mitigated by the project proponent through the creation of new wetlands. The mapping program cannot distinguish newly created wetlands from naturally existing wetlands. The values provided in the following summary are, therefore, conservative because they do not fully account for mitigated impacts. Because both the federal and state governments have "no net loss" policies for wetlands, legally "lost" wetlands have been mitigated at a replacement ratio of at least 1:1.

For the MassDEP Southeast Region (which includes the 31 South Coast Rail study area municipalities in Massachusetts), 545 acres of wetlands were lost from 1990 to 2001 (49 to 68 acres lost per year).[39] For the period from 2001 to 2005, 264 acres of wetlands were lost (66 acres per year) in the Southeast Region. These losses represent 62 percent of total wetland losses across the state during this time.[40] Currently, there are approximately 126,464 acres of wetlands in the 31 South Coast Rail study area municipalities located Massachusetts.[41] Conservatively assuming a consistent 66-acre-per-year loss rate,[42] 124,748 acres of wetlands would remain in 2035 (without considering mitigation under the state and federal "no net loss" requirements).

The wetlands loss mapping project allows for specific identification of conversion types, but data are not readily available at the regional level. Statewide, principal activities causing wetland loss varied. Table

[41] MassGIS database: http://www.mass.gov/mgis/massgis.htm. Accessed 5 October 2009.

[42] This value is conservative because it represents the average annual loss in the DEP's Southeast Region, which is larger than the 31-community South Coast Rail study area.

5.4-4 identifies wetland losses attributed to 11 conversion types in 2004 and 2006. These data show a relative consistency of the percentage of wetland impacts attributable to residential development, at 22.5 percent in 2004 and 19.3 percent in 2006, for an average of 20.9 percent. Using this average and the average annual conversion rate of 66 acres per year in the MassDEP Southeast Region, approximately 13.8 acres of wetland loss per year can be attributed to residential development.

Table 5.4-4 Comparison of Statewide Wetland Conversion Types in 2004 and 2006

	Percentage of Total Conversion

Source: DEP. 2009. *Wetlands PPA Summary and Workplan*. Commonwealth of Massachusetts, Department of Environmental Protection: Boston.

It is not possible to define project-specific wetland losses that have or may occur from each of the recent or reasonably foreseeable activities evaluated in this chapter. Some projects have received or applied for wetland permits with the Corps and/or MassDEP, but there is not a clear indication of how recent wetland loss trends may change as a result of these and other projects. Lacking comprehensive project-specific data, it is reasonable to assume that the estimated 66 acres loss per year based on MassDEP recent data for the Southeastern Region would continue for the foreseeable future.

Chapter 4.16, *Wetlands*, concludes that direct permanent federal impacts to Waters of the U.S. under the electric versions of the Stoughton and Whittenton Alternatives would be 12.3 and 11.2 acres, respectively. Impacts of diesel alternatives would be slightly less than the electric alternatives. Based on regulatory requirements, these impacts would be mitigated at a 1:1, 2:1, or 3:1 ratio, depending upon the habitat type impacted. Therefore, direct wetlands impacts from the South Coast Rail project would not result in a net loss. As described in Chapter 4.16, 34.0 acres of wetlands are anticipated to be restored, replaced, or created to offset direct impacts of the Stoughton Alternatives and 31.0 of wetlands are anticipated to be restored, replaced, or created to offset direct impacts of the Whittenton Alternatives.

Under Scenario 1, wetland losses from induced growth are estimated to be 7.35 square feet per new household. This would decrease to between 5.15 to 5.81 square feet per new household with the implementation of smart growth measures under Scenario 2. Under Scenario 1, approximately 124,754 to 124,756 acres of wetlands would remain in 2035 under the Whittenton and Stoughton Alternatives, respectively. For Scenario 2 there would be a net increase of 9.5 to 12.0 acres, therefore approximately 124,757 to 124,760 acres of wetlands would remain in 2035, based on low to high implementation of smart growth measures under Scenario 2 of the Build Alternatives.

Table 5.4-5 provides an overview of direct and indirect effects and includes the consideration of mitigation measures to identify total wetland area in 2035 under the Build Alternatives. Mitigation for wetland losses indirectly resulting from the project are not included in this evaluation because mitigation ratios are unknown but would likely range from 1:1 to 3:1. It is assumed that mitigation would result in a replacement greater than 1:1 (e.g., no net loss); thus, there would be an increase in wetlands remaining in 2035 under the Build Alternatives as compared to the No-Build Alternative.

Table 5.4-5 Cumulative Impacts to Wetlands in 2035 (in acres)

			Wetlands			
Historical Trends Affecting Wetlands	**Trends and Current or Future Actions Affecting Wetlands**	**Alternative**	**Project Direct and Indirect Effects**	**Wetlands Remaining in 2035**	**Change from No-Build**	**% Change from No-Build**
Historical wetland loss; recent Federal and State wetland regulations	No net loss policy; mitigation (replacement) ratios from 1:1 to 3:1	No-Build	N/A	124,748	N/A	N/A
		Build Alternatives				
		Scenario 1				
		Stoughton	8.1	124,756	8.0	0.01%

		Scenario 2				
		Stoughton	11.3 to 12.0	124,759 to 124,760	11.3 to 12.0	0.01%
		Whittenton	9.5 to 10.2	124,757 to 124,758	9.5 to 10.2	0.01%

.

5.4.4 Biodiversity

Biodiversity is not regulated by federal, state, or local agencies. However, evaluation of project impacts to biodiversity is typically a component of NEPA and MEPA analyses for federal and state agencies. This evaluation of the cumulative impacts to biodiversity is based, in part, on historical data from non-governmental sources rather than regulatory agency records.

Loss of biodiversity is linked to increases in land use: undeveloped land has higher biodiversity than developed land. Historical trends in land conversion, therefore, assist in understanding trends in loss of biodiversity. The Corridor Plan states that "more land had been developed in the South Coast region since 1960 than in the previous 340 years and that land development was occurring at 2.5 times the rate of population growth." At a more detailed level, the MassAudubon's *Losing Ground* report series includes an analysis of land use changes throughout Massachusetts from 1971, 1985, 1999, and 2005 data. The report notes that statewide 22 acres of natural land were developed per day during the period between 1999 and 2005, as compared to 40 acres per day between 1985 and 1999. Although land conversion is ongoing, the trend is of decreasing rates of conversion.

As described in Chapter 4.2, *Land Use*, and according to *Losing Ground*, natural (undeveloped) land in 2005 for the 31 South Coast communities in Massachusetts totaled 347,263 acres. In the period from 1999 to 2005, 7,888 acres (2.2 percent of the 1999 total) in those 31 communities had been converted from natural land to developed land. It is assumed that the natural-to-developed land conversion rates calculated by MassAudubon are likely to continue for the foreseeable future. Based on this rate, by 2035

approximately 39,450 acres of natural land would be converted to developed land. This is slightly greater than the amount of land conversion estimated under the No-Build Alternative (38,892 acres). Under the Build Alternatives, between 27,995 acres and 40,184 acres would be converted to support residential development by 2035 depending on which scenario is implemented (see Table 5.3-3). Assuming that natural land is developed as projected under the South Coast Rail project, between 307,079 acres and 319,268 acres of natural land would remain in 2035.

Several plots of land throughout the South Coast region have been set aside for conservation purposes, including the preservation of biological resources (see Chapter 4.10, *Open Space and ACEC*). One example would be the Southeastern Massachusetts Bioreserve (Bioreserve), a 13,600-acre area just east of Fall River, which was established to protect, restore, and enhance the biological diversity and ecological integrity of a large ecosystem representative of the region.[43] The Bioreserve comprises portions of the Freetown/Fall River State Forest, Acushnet Wildlife Management Area, watershed and conservation lands owned by the City of Fall River, and the former Acushnet Saw Mills property. The Bioreserve land is owned by the Commonwealth of Massachusetts, City of Fall River, and Trustees of Reservations. Lands for the Southeastern Massachusetts Bioreserve are still being acquired. There will be no economic development activities within the protected lands of the Bioreserve.

At least one recent project has specifically converted undeveloped to developed land, affecting biodiversity in the South Coast region. The golf course adjacent to the Great Woods Conservation Area in Mansfield converted 400 acres of forest land to developed land (landscaped golf course and appurtenant facilities).[44] Somewhat more historically, the construction of the numerous linear transportation facilities (surface streets, highways, and railroads) as well as utility corridors (aerial electric transmission lines and pipelines) from the late 1800s through the present time has fragmented the landscape, reducing biodiversity by segregating populations of low-mobility species by creating physical or psychological barriers to movement. Highway construction projects, such as I-195 and I-495, continued until the late 1900s.

Several reasonably foreseeable future actions could adversely impact biodiversity:

- Implementation of the Taunton Comprehensive Wastewater Management Plan may impact diadromous fish populations within the Taunton River and Three Mile River.[45]

- Numerous ongoing or anticipated developments throughout the South Coast region, as outlined in the Corridor Plan, will likely convert natural land to developed land. (Note, however, that many of these developments do not qualify as "reasonably foreseeable future actions" as defined above.)

As mentioned above, no new highway projects are currently anticipated in the South Coast region, therefore, biodiversity would not be impacted by any planned transportation improvements.

[45] EEA. 2009. Certificate of the Secretary of Energy and Environmental Affairs on the Notice of Project Change, Comprehensive Wastewater Management Plan (Winthrop Street, Davenport Terrace, Williams Street Sewer Extension). Commonwealth of Massachusetts, Executive Office of Energy and Environmental Affairs: Boston.

Historic trends and current or future projects suggest that land development in the South Coast region is likely to continue for the foreseeable future. As discussed in MassAudubon's *Losing Ground* report series and reflected in the Corridor Plan, development generally propagates outward from the Boston metropolitan area, with a "sprawl frontier" of urban-character communities in the northern portion of the South Coast region and decreasing development density farther south into suburban and rural communities. Accordingly, there is a potential for greater conversion in the southernmost communities because the northernmost communities have already converted much of their land. Although the rate of conversion has slowed in recent years, the South Coast communities have not reached build-out. The South Coast region will likely experience continued loss of biodiversity correlated with land development in the foreseeable future irrespective of the South Coast Rail project.

In addition to these identifiable, specific human activity trends and projects, global warming may have local effects on biodiversity. Recent studies predict the effects of climate change in New England that could dramatically change the distribution of plant communities and some animal species. New England's average summer temperatures are anticipated to increase by 2 to 3°F by 2040, and by 6 to 14°F by the end of the century, resulting in a summer climate similar to that of North Carolina.[46] Winters are also predicted to be warmer, by 8 to 12^{0}F, with fewer snow-covered days. These changes are expected to be accompanied by longer growing seasons, increasing by 4 to 6 weeks by 2099.

These changes are predicted to affect the distribution of plant species, with most tree species shifting their range north by at least 300 miles. The effects are highly uncertain; however, Frumhoff et al. predict that Southeastern Massachusetts would likely retain the same dominant forest type.[47] Changes in plant distributions are likely to occur more slowly than for animals, as a result of the longer generation times, and that changes in vegetation are likely to be complex and result from a combination of the effects of changing temperature, precipitation, snow cover, and other factors.[48]

Sea level, which has been rising since the end of the last glaciations, is predicted to accelerate. Even in the absence of climate change, sea levels will be 6 inches higher by 2099. There is a range of predictions for the added effects of climate change, from 17 inches to more than 4 feet (assuming that the Greenland ice cap does not melt catastrophically). Sea level rise could result in the loss of much of New England's coastal salt marshes if sediment accretion does not keep pace with sea level rise and if topography and development at the current upland edges of salt marshes do not allow marshes to migrate landward.

Predictions for animal communities also suggest that some bird and mammal species could shift distributions northward as forest plant community composition and temperature extremes change. This is particularly the case for species whose present northern limit is linked to winter temperatures and snow cover. Warmer winters and less snow cover could allow these species to expand into New England. Other concerns with regard to wildlife habitat include changes in hydrography and increasing temperatures of stream waters, potentially affecting reproduction or survival of cold water fish, or changes in precipitation patterns that potentially alter the hydroperiod of vernal pools and affect reproductive success of obligate vernal pool amphibians. Vernal pools are particularly sensitive to change in precipitation and evapotranspiration rates. Climate change predictions of more episodic

[46] Frumhoff, P.C., J.J. McCarthy, J.M. Melillo, S.C. Moser, D.J. Wuebbles. 2007. *Confronting Climate Change in the U.S. Northeast: Science, Impacts, and Solutions.* Synthesis report of the Northeast Climate Impacts Assessment (NECIA), Cambridge MA: Union of Concerned Scientists. USC Publications

[47] Ibid.

[48] Bertin, R.I. 2008. Plant phenology and distribution in relation to recent climate change. J. Torrey Bot. Soc. 135: 126-146.

precipitation and increased evapotranspiration rates suggest that vernal pools would dry earlier in the year and stay dry longer.[49]

With these exceptions, plant and animal communities within the South Coast Rail study area are not anticipated to change substantially with projected climate change because these areas primarily support plant and animal communities with a more southern coastal plain distribution (the coastal plain extends from New Hampshire to Virginia), rather than the more vulnerable northern forest communities of northern New England. Salt marshes, cold-water fisheries, and vernal pools are the most vulnerable elements of the South Coast area.

The Stoughton and Whittenton alternatives would directly impact 11.2 to 12.3 acres of vegetated wetlands and 182 to 188 acres of upland wildlife habitat. Table 5.4-6 shows that the indirect effect on biodiversity from the Stoughton and Whittenton Alternatives under Scenario 1 would be the loss of 120,551 acres of habitat. The table compares combined historic trends in land conversion, recent or reasonably foreseeable future actions, and the range of land conversion that would result from the No-Build Alternative and under the two scenarios of the Stoughton and Whittenton Alternatives.

Table 5.4-6 Cumulative Biodiversity Impacts in 2035

Historical Trends affecting Biodiversity	Trends and Current or Future Actions Affecting	Alternative	Land Conversion (acres of reduced value)			
			Project Direct and Indirect Effects[1]	Natural Land Remaining in 2035	Change from No-Build	% Change from No-Build
40 acres per day land conversion; ecosystem fragmentation	22 acres per day land conversion; additional habitat degradation; climate change	No-Build	N/A	307,813	N/A	N/A
		Build Alternatives				
		Scenario 1				
		Stoughton	120,605	303,883	-3,933	-1%
		Whittenton	120,595	303,893	-3,920	-1%
		Scenario 2				
		Stoughton	58,760 to 75,021	349,467 to 365,728	+41,654 to +57,915	+14% to +19%
		Whittenton	58,750 to 75,011	349,477 to 365,738	+41,664 to +57,925	+14% to +19%

1 The four high-biodiversity habitat types (upland, wetland, vernal pool- wetland, and vernal pool- supporting upland) have been summed only to illustrate the area of land conversion; they are not of equivalent biodiversity value.

Approximately 307,813 acres of natural land would remain in the South Coast region in 2035 under the No-Build Alternative, after 116,675 acres of habitat loss. For the Stoughton Alternative under Scenario 1, approximately 303,883 acres of natural land would remain, after 120,605 acres of habitat loss. For Scenario 2, approximately 349,467 to 365,728 acres of natural land would remain, with low and high implementation of smart growth measures, respectively, after between 58,760 and 75,021 acres of habitat loss. The cumulative impacts of the Whittenton Alternative would be very similar to the Stoughton Alternative.

[49] Brooks, R.T. 2004. Weather-related effects on woodland vernal pool hydrology and hydroperiod. In *Wetlands.* (Vol. 24, No. 1, pp 104-114). The Society of Wetland Scientists.

Under Scenario 1, the Build Alternatives would result in approximately 1 percent more conversion of undeveloped land as compared to the No-Build Alternative. Under Scenario 2, the Build Alternatives would result in 14 to 19 percent less conversion of undeveloped land than the No-Build Alternative.

Recent trends in land conversion and concomitant biodiversity loss described above in combination with the impacts from the Build Alternatives would:

- Under Scenario 1, result in little additional land conversion and habitat loss as compared to the No-Build Alternative, with resultant minimal impacts to biodiversity. A slight increase in the area of degraded habitat would also be realized in this scenario; or

- Under Scenario 2, contribute less to land conversion and habitat loss than the No-Build Alternative, with lower resultant impacts to biodiversity. Substantively less area of habitat would be degraded in this scenario.

5.4.5 Threatened and Endangered Species

Rare species are protected at the federal level by the US Fish & Wildlife Service, or the National Marine Fisheries Service, under the authority of the Endangered Species Act (ESA). At the state level, the Massachusetts Department of Fish and Wildlife (DFW) is responsible for administering the Natural Heritage and Endangered Species Program (NHESP) under the Massachusetts Endangered Species Act (MESA). Both classify rare species according to their risk of extinction, prohibit “take” of species except as authorized by permit (and usually requiring mitigation), and implement plans to assist in the recovery of those species.

Historical development of the South Coast region has impacted native plants and animals to the extent that some species are now rare and have received legal protection under state or federal law. Under MESA, an “Endangered” species is one that is in danger of extinction throughout all or a significant portion of its range within Massachusetts. A “Threatened” species is one that is likely to become endangered in Massachusetts in the foreseeable future. Species of Special Concern are those species where biological research has documented to have suffered a decline that could threaten the species if the decline continues unchecked, or those species that occur in such small numbers or with such a restricted distribution that they could easily become threatened within the Commonwealth. Similar definitions are used at the national level under ESA. Several state-listed rare species that are present in the South Coast region may be affected by the South Coast Rail project, as described in Chapter 4.15, *Threatened and Endangered Species*. No federally listed species would be affected by the South Coast Rail project. Table 5.4-7 identifies potentially impacted species and threats to each.

Historical and ongoing land development has converted natural land and altered wetlands and vernal pools, as described in Chapter 4.14, *Biodiversity*, *Wildlife, and Vegetation*; Chapter 4.2, *Land Use and Zoning*; and Chapter 4.16, *Wetlands*. A species now protected by either the ESA or MESA has been likely been adversely impacted by such historical activities. Federal and state laws, enacted in 1973 and 1990, respectively, now prohibit “take” of individuals and/or adverse impacts to their habitat except as permitted and usually with some mitigation requirement. Any major federal or state action (including providing funding or issuing a permit by an agency) requires analysis of impacts to listed species. Typically, projects adversely affecting listed species are not approved without a mitigation requirement. Project impacts to certain habitat types, such as wetlands and vernal pools, also typically require mitigation (for example, the “no net loss” policy for wetlands). However, some of the threats to listed species are not subject to ESA or MESA regulations.

Table 5.4-7 State-Listed Species Potentially Impacted by the South Coast Rail Project

Species	Listing Status	Threats
Marbled Salamander (*Ambystoma opacum*)	Threatened	Loss, degradation and fragmentation of both aquatic breeding pool habitat required for reproduction and terrestrial habitat needed for foraging, overwintering, growth and development to development and urbanization.
Blue-Spotted Salamander (*Ambystoma laterale*)	Species of Special Concern	Loss, degradation and fragmentation of both aquatic breeding pool habitat required for reproduction and terrestrial habitat needed for foraging, overwintering, growth and development to development and urbanization.
Wood Turtle (*Clemmys insculpta*)	Species of Special Concern	Hay-mowing operations, development of wooded stream banks, roadway casualties, incidental collection of specimens for pets, unnaturally inflated rates of predation in suburban and urban areas, forestry and agricultural activities, and pollution of streams.
Blanding's Turtle (*Emydoidea blandingii*)	Threatened	Habitat loss, degradation, and fragmentation (i.e., roads) driven by commercial and residential expansion. Other threats include illegal collection, unnaturally inflated rates of predation in suburban and urban areas, agricultural and forestry practices, and natural succession (i.e., loss of nesting habitat).
Eastern Box Turtle (*Terrapene carolina*)	Species of Special Concern	Habitat destruction resulting from residential and industrial development; road mortality; collection by individuals for pets; mowing of fields and early successional habitat during the active season; unnaturally inflated rates of predation in suburban and urban areas; disturbance of nest sites by ATVs; and genetic degradation due to the release of non-native (pet store) turtles.
Mocha Emerald (*Somatochlora linearis*)	Species of Special Concern	Stream damming or alteration; chemical pollution.
Hessel's Hairstreak (*Callophrys hesseli)*	Species of Special Concern	Habitat loss; suppression of disturbance (fire, flooding), or excessive deer browsing, preventing regeneration of Atlantic white cedar; hydrologic alteration; invasion by exotic plants; introduced generalist parasitoids; insecticide spraying
Pale Green Pinion Moth (*Lithophane viridipalle)*	Species of Special Concern	Habitat loss; hydrologic alteration; invasion by exotic plants; introduced generalist parasitoids; insecticide spraying; light pollution.
Water-Willow Stem Borer Moth (*Papaipema sulphurata)*	Species of Special Concern	Habitat loss; hydrologic alteration; invasion by exotic plants; introduced generalist parasitoids; insecticide spraying; light pollution.
Ringed Boghaunter (*Williamsonia lintneri)*	Endangered	Artificial changes in water level and various forms of pollution (such as agricultural and road runoff), septic system failure, insecticide spraying.
Long's Bulrush (*Scirpus longii*)	Threatened	Changes in the water quality and the natural fluctuating hydrologic regime of its habitat, invasion by exotic invasive plants, and exclusion of fire disturbance.

Source: NHESP Website: http://www.mass.gov/dfwele/dfw/nhesp/species_info/mesa_list/mesa_list.htm. Accessed 8 October 2009.

The New Bedford Airport Improvement Project is an example of an action in the South Coast region with potential impacts to protected species, particularly the eastern box turtle (*Terrapene carolina*) (Chapter 4.15, *Threatened and Endangered Species*). This project is required to obtain and comply with a Conservation and Management Permit to mitigate impacts to this species.

As described in Chapter 4.15, *Threatened and Endangered Species*, the South Coast Rail project would also include mitigation of direct or indirect effects to listed species' habitat, resulting in a net benefit to those species. Indirect effects from induced growth would be regulated by the ESA or MESA, and

relevant habitat protection laws for wetlands and vernal pools. Because of the overriding ESA and MESA regulations, there would be no difference in cumulative impacts to threatened or endangered species under the two scenarios even with full implementation of PPAs.

Several state-listed species could potentially experience cumulative adverse effects from the loss of habitat quality associated with habitat fragmentation from land development or climate change, as discussed in Chapter 4.14. Eastern box turtles and vernal pool species (marbled and blue-spotted salamanders [*Ambystoma opacum, A. laterale*], Blanding's turtles [*Emydoidea blandingii*]) could continue to decline as a result of these indirect effects.

In summary, federal and state laws and regulatory programs protect threatened or endangered species and certain habitat types. Regulatory protections prevent long-term adverse impacts to listed species. Because the MESA process requires net benefit measures for all projects, there would not be continued losses of listed species under the No-Build Alternative. As previously described, indirect effects on habitat quality and connectedness would be greater under Scenario 1 for the Build Alternatives, and would be reduced in Scenario 2 to levels below the No-Build Alternative.

5.4.6 Water Quality

Surface water quality is regulated by the USEPA under Section 402 of the CWA. Relevant CWA programs include the National Pollutant Discharge Elimination System (NPDES) (which regulates discharges of wastewater and storm water to certain surface water bodies), and the Total Maximum Daily Load program (regulating discharges of pollutants into certain water bodies with designated uses; this program has been delegated to DEP). Most construction-related discharges are subject to EPA's Construction General Permit, which requires a Stormwater Pollution Prevention Plan, among other requirements.

Surface water resources are protected at the state level under several laws and regulatory programs, including the Massachusetts Clean Waters Act (MCWA). Other applicable rules, regulations, and guidance include the Massachusetts Wetlands Protection Act and Wetlands Protection Act Regulations, Massachusetts Public Waterfront Act and Waterways Regulations, the Surface Water Quality Standards, the proposed Stormwater Management Regulations, and the Massachusetts Stormwater Management Handbook.

As with other physical resources (such as biodiversity and wetlands), water quality in the South Coast region has been adversely impacted by historical activities but increasingly stringent federal and state regulatory controls over the past several decades have resulted in substantive improvements. Many surface water bodies and groundwater resources have been classified for specific uses and are protected for those uses. Point source and non-point source discharges to surface water bodies are regulated, and special protections are afforded to either outstanding resource waters (those with exceptional values) or impaired waters (those that do not meet standards for their designated use). Groundwater supply protection areas have been similarly established to protect aquifers that are used for public water supplies. Chapter 4.17, *Water Resources*, provides a summary of the relevant regulatory programs and designations for each classified water resource in the South Coast Rail study area.

All potential sources of discharges to surface water bodies or groundwater resources must comply with relevant regulatory requirements. Accordingly, none of the reasonably foreseeable future actions listed above would result in a decrease of surface or groundwater quality.

The South Coast Rail project would not adversely impact water quality. The project would not require any process water discharges, and storm water discharges from the railroads, stations, or layover facilities would be managed in compliance with a Storm Water Pollution Prevention Plan (SWPPP) and state stormwater standards. With the required mitigation and drainage features in place, the Build Alternatives are not expected to contribute contaminants that would impair surface or groundwater resources (Chapter 4.17, *Water Resources*).

Development could indirectly affect water quality through nonpoint sources such as runoff from lawns (containing fertilizers, herbicides or pesticides). An increased number of septic systems in municipalities without sewer and wastewater treatment could also affect groundwater quality through the addition of nutrients, potentially increasing eutrophication in surface water bodies. As previously documented, there would be minor differences between the No-Build Alternative and the Build Alternatives under Scenario 1. Each of these could result in indirect effects to surface or groundwater quality. Although not quantifiable at this phase of project design, it is anticipated that land development under Scenario 2 would result in less pavement, due to cluster development, and less stormwater runoff than Scenario 1. Development in Scenario 2 is also anticipated to reduce lawn area, and would therefore have a slight reduction in potential indirect water quality effects. Therefore, Scenario 2 is anticipated to reduce cumulative water impacts over the No-Build Alternative and Scenario 1 of the Build Alternatives.

5.4.7 Air Quality

This section discusses the cumulative impacts of the South Coast Rail project to ambient air quality and GHG emissions. As discussed in Chapter 4.9, *Air Quality*, hazardous air pollutant emissions from mobile sources are not anticipated to be a substantial aspect of the South Coast Rail project and are therefore not discussed in this analysis.

Air quality in Massachusetts is regulated by the EPA within various programs of the federal Clean Air Act and by MassDEP under the Massachusetts Clean Air Act and the Global Warming Solutions Act. Certain projects must be evaluated for impacts to ambient air quality, GHG emissions, and hazardous air pollutant emissions. Controls or offsets of these emissions are often required as part of facility operating permits. States are required to develop and implement plans to improve ambient air quality when thresholds are exceeded for certain pollutants.

5.4.7.1 Ambient Air Quality

The existing ambient air quality in the South Coast region reflects past actions and regulatory controls. The USEPA regulates emissions of six "criteria pollutants" under the National Ambient Air Quality Standards (NAAQS) program.[50] The USEPA has designated all three South Coast counties (Bristol, Norfolk, and Plymouth)[51] as in non-attainment status for ozone NAAQS but in attainment status for all other criteria pollutants.[52] MassDEP has prepared a State Implementation Plan (SIP) describing how the

[50] USEPA. 2009. *Six Common Air Pollutants*. EPA website: http://www.epa.gov/air/urbanair. Accessed on 25 September 2009.
[51] The entire state does not meet the ozone NAAQS.
[52] USEPA. 2009. County Air Quality Report- Criteria Pollutants, Geographic Area: Massachusetts, Year: 2008. USEPA website: http://iaspub.epa.gov/airsdata/adaqs.summary?geotype=st&geocode=MA&geoinfo=st%7EMA%7EMassachusetts&year=2008&fld=county&fld=stabbr&fld=regn&rpp=25. Accessed on 25 September 2009.

ozone NAAQS will be met by the end of the 2009 monitoring season.[53] MassDEP projections were made with a model that takes into consideration state and county growth factors.

Air quality monitoring shows a recent trend of decreasing volatile organic compounds (VOCs) and nitrogen oxides (NO_x) emissions (in the presence of sunlight and heat, VOCs and NO_x react to form ozone). New federal rules on emissions and fuel standards for non-road mobile sources (such as locomotives), as well as regulations on numerous other source products, will contribute to these anticipated reductions.

The electrification of the Northeast Corridor reduced diesel locomotive usage, resulting in lower emissions of air pollutants, and likely beneficially impacting ambient air quality.

The construction of proposed industrial, business, or commercial parks in Fall River and Freetown, and at Great Woods in Mansfield would increase automobile traffic, resulting in more emissions of air pollutants than if these projects were not built. However, none of these projects would result in exceeding NAAQS. Even with these projects ambient air quality is expected improve over the current conditions due to increasing regulatory controls.[54] Although traffic would be increased, regulatory controls such as federal automobile emission standards and state vehicle inspection programs would reduce emissions.

The South Coast Rail project would not adversely impact ambient air quality. None of the alternatives would result in exceeding any of the NAAQS for the six criteria pollutants (Chapter 4.9, *Air Quality*). There is less than one-tenth percent variation in emissions between the alternatives, including either electric- or diesel-powered train options of the Build Alternatives.

Ambient air quality in 2035 would be improved over current conditions, even with the projected growth in the region, due to both regulatory controls and the reduced rate of growth in traffic that would result from use of the transit system. The South Coast Rail project is expected to beneficially impact air quality indirectly. Compared to the No-Build Alternative, vehicular movements (in terms of VMT) under the Build Alternatives would be reduced by up between 197,500 and 252,200 VMT daily, with resultant reduction in emissions of regulated air pollutants (see Table 5.3-9).[55]

There would be no significant difference in ambient air quality cumulative impacts under the No-Build and Build Alternatives.

5.4.7.2 Greenhouse Gases

GHG monitoring at the federal level has been conducted since 1990, and the U.S EPA recently initiated a program regulating GHGs for large sources.[56] The most recent data available are from 2007 and, compared to 1990 data, indicate that total national GHG emissions have increased by 17 percent over

[56] USEPA. 2009. Final Mandatory Reporting of Greenhouse Gases Rule. USEPA website: http://www.epa.gov/climatechange/emissions/ghgrulemaking.html. Accessed on 25 September 2009.

those 17 years.[57] GHG emissions attributed to transportation sources principally from fossil fuel consumption increased 27 percent over the same time period (an average of 1.6 percent per year).

At the state level, GHG emissions in 1990 have been used as a baseline to establish projections to 2020.[58] GHG reduction targets are to be developed for each decade from 2020 to 2050,[59] beginning with a target between 10 and 25 percent reduction (as compared to 1990 levels) and culminating in at least an 80 percent reduction by 2050.[60] The 1990 data indicate that GHG emissions attributable to transportation sources were 28.9 million metric tons of carbon dioxide equivalent ($MMTCO_{2e}$). Lacking current state-specific data of GHG emissions but assuming that the nation-wide increase in transportation GHG emissions are similarly increasing at the state level, approximately 36.7 $MMTCO_{2e}$ were emitted by the transportation sector in Massachusetts in 2007. It is not possible to predict what either the regulatory limit for nor what the actual rate of GHG emissions may be in 2035.

The EPA's recent rule requiring reporting of GHG emissions applies to large GHG emission sources: facilities that emit more than 25,000 metric tons of carbon dioxide per year. Numerous other EPA regulatory programs are addressing greenhouse gas emissions from other sources, including vehicle emission standards for heavy-duty vehicles,[61] and standards for 2017-2025 model year cars and trucks adopted in 2012.[62]

The construction of proposed industrial, business, or commercial parks in Fall River, Freetown, and Mansfield will likely contribute GHGs into the atmosphere due to increased VMT. For example, the Crossroads at 24 project in Fall River is required to conduct mesoscale air quality analyses for VOC and NO_x emissions for compliance with MassDEP's Greenhouse Emissions Policy and Protocol. As with the ambient air quality, this project would result in GHG emissions but modeled air pollutant concentrations in the future (2035) are lower than current concentrations due to increasing regulatory controls.[63]

The South Coast Rail project would result in direct and indirect GHG emissions. Although all project alternatives (including the electric- or diesel-powered train options) would result in direct GHG emissions, the modeled emissions are less than would occur under the No-Build Alternative (Chapter 4.9, *Air Quality*). Automobile traffic (VMT) would be reduced, with resultant comparative reduction in GHG emissions (Chapter 4.9, *Air Quality, Table 4.9-20: Summary of the 2030 Mesoscale (Regional) Air Quality Analysis for the South Coast Rail Alternatives)*.

The South Coast Rail project would result in GHG emissions from induced growth. Table 5.4-8 compares the calculated direct and indirect transportation-related, as well as residential growth, 2035 GHG emissions for each alternative from the Business as Usual scenario.

The data suggest a very minor change from the No-Build Alternative in greenhouse gas emissions that would directly or indirectly result from the South Coast Rail project. Fewer miles would be traveled for all alternatives, offsetting the growth in the number of households for each alternative.

Table 5.4-8 Greenhouse Gas Emissions in 2035

Historical Trends affecting Greenhouse Gas Emissions	Trends and Current or Future Actions affecting Greenhouse Gas Emissions	Alternative	Greenhouse Gas Emissions (CO_2 tpy)			
			Project Direct and Indirect Effects	GHG Emissions in 2035	Change from No-Build	% Change from No-Build
Increasing greenhouse gas emissions	Decreasing greenhouse gas emissions due to new state and federal controls despite additional sources	No-Build	N/A	28,691,855	N/A	N/A
		Build Alternatives				
		Scenario 1				
		Stoughton	33,168	27,842,309	-849,546	2.9
		Whittenton	33,168	27,842,309	-849,546	2.9
		Scenario 2				
		Stoughton	<33,168	<27,842,309	>-849,546	>2.9
		Whittenton	<33,168	<27,842,309	>-849,546	>2.9

Note: Assumes 11.83 CO_2 tpy for all alternatives.

The cumulative impacts evaluation combines the historical activities, regulatory controls, and reasonably foreseeable future actions with the greenhouse gas emissions that are anticipated from the South Coast Rail project. As with ambient air quality, within Scenario 1 greenhouse gas emissions in 2035 would be improved over current conditions for all alternatives, even with the anticipated growth in the region, due to both the regulatory controls and the reduced rate of growth in traffic that would result from use of the transit system. It is not possible to predict the greenhouse gas emission level limits that may arise from the regulations mentioned above; it is only known that the limits will be some percentage lower than the 1990 emission levels. In any case, compared to the No-Build Alternative, automobile traffic (in terms of VMT) would be reduced, with resultant reduction in emissions of greenhouse gases, as presented in Chapter 4.9, *Air Quality, Table 4.9-20: Summary of the 2030 Mesoscale (Regional) Air Quality Analysis for the South Coast Rail Alternatives*. The increase in households would, of course, increase associated greenhouse gas emissions over the No-Build Alternative. In either case, however, greenhouse gas emissions will be cumulatively reduced because of the regulatory requirements to reduce greenhouse gas emissions as compared to 1990 levels.

Scenario 2 is anticipated to reduce greenhouse gas emissions but the reductions may not be measurable at the regional level. As shown in Table 5.2-2, there would be no measurable difference in greenhouse gas emissions by household within Scenario 2. The location of the sources would differ (i.e., concentrated in PDAs instead of dispersed throughout the region) but the total emissions from stationary sources would not. Sprawl would be reduced, as compared to Scenario 1, because development would be concentrated close to station sites and in PDAs, presumably resulting in less personal car use and therefore lower greenhouse gas emissions.[64]

[64] EOT. 2009. *Smart Energy/Smart Growth Toolkit: Transit-Oriented Development (TOD)*. Commonwealth of Massachusetts, Executive Office of Transportation and Public Works website: http://www.mass.gov/envir/smart_growth_toolkit/pages/mod-tod.html. Accessed 25 September 2009.

As described in Section 5.3, forest clearing would likely reduce carbon sequestration, but cannot be quantified at this time. Changes in carbon sequestration would be proportional to the amount of land cleared for each alternative and scenario.

Combined with the improvements in greenhouse gas emissions required by regulatory standards described above, the cumulative impacts from the Build Alternatives would:

- Under Scenario 1, contribute additional GHG but, depending upon the alternative selected, at minimally lower or higher rates than the No-Build Alternative, or
- Under Scenario 2, also contribute additional GHG but, depending upon the alternative selected, at minimally lower or higher rates than the No-Build Alternative. The greenhouse gas emission source locations may vary, but the overall (regional) reduction as compared to the Business as Usual scenario may be immeasurable.

There would be no significant differences between the alternatives in the cumulative impacts to global climate change from greenhouse gas emissions.

5.4.8 Economy

The evaluation of potential project-induced impacts to economic conditions is typically a component of analyses conducted for federal and state agencies. Because governments are typically funded, in part, by taxes, tracking tax revenue streams often provides a good measure of the economy.

Local, state, and federal agencies monitor (measure) various economic metrics. As described in the Corridor Plan, the "South Coast rail alternatives will improve accessibility and mobility in the South Coast region, and these improvements are expected to stimulate additional business sales, jobs, household income, and state and local taxes beyond that forecast in the absence of such improvements."[65] This evaluation of the cumulative impacts to the economy that may result from the South Coast Rail project is based on projected impacts to households and population, economic activity and jobs, and tax revenues.

It is anticipated that economic impacts would be recognized at different locations across the South Coast region under Scenario 1 and Scenario 2 because the implementation of smart growth measures under Scenario 2 would distribute development differently than demonstrated under existing conditions and projected under Scenario 1.

5.4.8.1 Household Size and Population

As presented in Table 5.3-2, household growth in the South Coast region from 2000 to 2035 is anticipated to total 75,212 new households under the No-Build Alternative. Assuming an average household size of 2.5 persons, the resident population of the South Coast region would increase by approximately 188,031 persons by 2035 under the No-Build Alternative. Based on a regional population of approximately 740,000 in 20098, the South Coast region population would be approximately 928,031 in 2035 under the No-Build Alternative.

[65] EOT. 2009. *South Coast Rail Economic Development and Land Use Corridor Plan.* Commonwealth of Massachusetts, Executive Office of Transportation and Public Works, and Executive Office of Housing and Economic Development. Prepared by Goody Clancy: Boston. See Chapter 5: Potential Economic Effects of South Coast Rail, and in particular Table 5-1: Economic Effects in 2030 of South Coast Rail (SCR) Rail Alternatives ($2007).

The Build Alternatives are projected to introduce an additional 2,802 to 2,804 households across the South Coast region by 2035. Assuming 2.5 people per household, this would result in an additional 7,005 to 7,010 people across the South Coast region over and above the No-Build Alternative. The incremental increase in population under the Build Alternatives represents less than 0.8 percent of the 2009 South Coast region population.

5.4.8.2 Jobs and Economic Activity

Extensive economic data characterizing the current economy are provided in the Corridor Plan.[66] Bristol County includes some three-quarters of the population and is almost entirely encompassed by the South Coast Rail study area (smaller portions of Plymouth and Norfolk counties are also within the project area). The employment base in Massachusetts grew by 53 percent between 1976 and 2006, while the Bristol County employment base grew by only 43 percent.[67] Seventy percent job growth was seen in Norfolk County and 109 percent in Plymouth County. The highest growth rates (statewide and in each county except Norfolk) were observed between 1981 and 1986, followed by negative growth (job loss) between 1986 and 1991.[68] With few exceptions, Bristol County experienced the least job growth (and greatest job loss) of the three South Coast counties over the 30-year period.

In the most recent period, total economic output in the South Coast Rail study area was over $50 billion in 2006, an increase of 18 percent from the 2001 output of $43 billion.[69] Grouping the broad range of industry sectors into four general types agricultural output represented 42.7 percent ($398 million), manufacturing represented 22.6 percent ($12 billion), services and trades represented 18.6 percent ($34 billion), and other production (mining, construction, and utilities) decreased represented 0.6 percent ($4 billion).

While economic output gained on average, the South Coast region lost 2,839 jobs during this period to total 374,832 in 2006, a decrease of less than 1 percent.[70] The greatest number of job losses was realized in the manufacturing sector, down from 51,833 to 40,633. This represents a nearly 22 percent loss but compares with state (23 percent) and national (21 percent) losses in the manufacturing sector in the same period. Job growth in sectors such as amusement & recreation, lodging, eating & drinking, wholesale trade, and real estate helped offset the shrinking of the manufacturing sector. The Corridor Plan estimates that there are currently 380,000 jobs the South Coast region.[71]

A number of the reasonably foreseeable future activities, as well as some more speculative projects, would introduce new economic activity and job in the South Coast region:

[67] Ibid. See in particular Appendix E: Baseline Report: Economic Development and Land Use Conditions in the South Coast Region Today, Chapter IV Economic Development Baseline.

[68] Ibid. See Appendix E: Baseline Report: Economic Development and Land Use Conditions in the South Coast Region Today, Chapter IV Economic Development Baseline, Figure 40: Employment Changes, 1976-2006.

[69] Ibid. See Appendix E: Baseline Report: Economic Development and Land Use Conditions in the South Coast Region Today, Chapter IV Economic Development Baseline, Table 25: Trends 2001-2006.

[70] Ibid. See Appendix E: Baseline Report: Economic Development and Land Use Conditions in the South Coast Region Today, Chapter IV Economic Development Baseline, Table 22: Employment Changes by Sector, 2001-2006.

[71] Ibid. See Chapter 5, Potential Economic Effects of the South Coast Rail.

- The proposed industrial, business, or commercial parks in Fall River and Freetown would increase business activity and add 11,000 jobs in these two communities[72] once the parks are occupied.

- Numerous other ongoing or anticipated developments throughout the South Coast, as outlined in the Corridor Plan,[73] are projected to increase business activity and add jobs in the region.

Many of these projects fall within the Southern Triangle portion of the South Coast Rail study area, therefore, the cumulative impacts would not differentiate between the Build Alternatives.

Historic and current data suggest that overall economic growth will continue in the South Coast region at a rate similar to the state as a whole. However, growth (or loss) will vary substantively between industries and communities and likely fluctuate during different time periods as a result of overall economic conditions. In general, economic activity is greatest in the northernmost communities (those closer to Boston) and communities already serviced by rail (such as the Northeast Corridor). Using the two geographic divisions described in the indirect effects analysis, the Corridor Plan predicts $52 billion in business activity in SCR 10 and $27 billion in SCR 21, for a total business output of $99 billion in 2030 under the No-Build Alternative.[74] The Corridor Plan does not analyze potential impacts in 2035.

Economic benefits would be recognized across the South Coast region during both the construction and operation of the Build Alternatives. Based upon the preliminary estimates of construction costs, the Corridor Plan states that "expenditures for labor and materials would generate construction period benefits of about 7,000 to 8,000 jobs, $1.4 to $1.8 billion in business output, and about $315 to $360 million in household income."[75] The Corridor Plan does not assign these impacts to individual communities or distinguish between the alternatives. By 2035, recognized economic benefits as a result of the South Coast Rail project are expected to contribute between $268 and $295 million in net new business output annually within the South Coast region and an additional $180 million to $192 million for the rest of the state.[76]

As described in Chapter 4.3, *Socioeconomics*, some job losses are anticipated as a result of business displacements to support the Build Alternatives, specifically at the Fall River Depot Station. The extent of such losses would depend on whether business owners relocate in the area. The size and number of businesses that would be displaced is not anticipated to affect overall municipal tax revenue in any significant way.

An additional 37,864 jobs would be introduced to the South Coast region by 2035 under the No-Build Alternative. This number is over and above the 380,000 estimated jobs in the Corridor Plan. Under Scenario 1 of the Build Alternatives, projections indicate an additional 1,341 jobs would be introduced to the South Coast region by 2035. Two fewer jobs would be introduced to the region under Scenario 2

than Scenario 1. An additional 1,200 to 1,260 jobs are estimated to result from the South Coast Rail project but occur elsewhere in the state.

Similar to population projections, economic activity and the job market are not expected to change on the regional level with the implementation of smart growth initiatives under Scenario 2. Locally, businesses may choose sites close to stations or municipalities with implemented smart growth measures such as TOD as compared to those that do not. However, it is not possible to project such fine-scale economic activity changes under Scenario 2.

5.4.8.3 Tax Revenue

The Corridor Plan identifies per-capita property tax receipts for selected South Coast communities in 2006.[77] These data indicate that tax receipts for communities that currently do not have train service (Fall River, New Bedford, and Taunton) are lower than for communities that currently do have train service (Attleboro, Foxborough, and Sharon).

Potential direct economic impacts from the Build Alternatives are outlined in Chapter 4.3, *Socioeconomics*. The analysis concludes that direct property tax revenue losses as compared to the total property tax receipts in affected municipalities would be minimal. Property acquisitions (converting privately owned parcels to publicly owned, thereby eliminating the property tax generated) would be minimal, and few business or residential displacements would result from the Build Alternatives.

Indirectly, property values are expected to increase near station sites due to increased access to transit but decrease along the Build Alternative alignments due to increased noise levels from train operations. It is assumed that residential property values would increase by 5 to 25 percent for residences within 1 mile of new station sites and decrease by up to 20 percent within about 400 feet of the alignments or layover facilities. It is not possible to predict with any precision the property tax revenue changes that may result for each community.

The Corridor Plan indicates that, under Scenario 1, the Build Alternatives would indirectly generate between $16 million and $18 million in net new state taxes and $8.5 million to $9.5 million in net new local business property taxes each year by 2030 as compared to the No-Build Alternative.[78] The expected changes for the Build Alternatives are not attributed separately. The Rapid Bus Alternative would generate approximately 60 percent of these values. The estimated overall growth (forecast regional growth plus growth attracted to station sites and new induced growth) near rail stations would result in $62 million to $77 million in local property taxes.[79] The Corridor Plan provides estimates through 2030.

The implementation of smart growth measures under Scenario 2 is expected to change the location of economic impacts such as property tax revenue sources in some South Coast study area communities, but is not expected to change overall (regional) impacts as compared to Scenario 1.

[79] Ibid. See in Table 5-2, Estimated Growth Near SCR Commuter Rail Stations by 2030.

5.4.8.4 Summary of Cumulative Economic Impacts

Combining the historic trends in the economy, recent or reasonably foreseeable future actions, and the varying effects on the economy that would result from the Build Alternatives, cumulative impacts of the South Coast Rail alternatives to the economy in 2035 for each alternative under the two scenarios are listed in Table 5.4-9.

The Build Alternatives would measurably benefit the economy in the South Coast region, with actual benefits at the municipal level distributed; the distribution of which would depend on whether smart growth measures are implemented. In all cases, the incremental addition of the project's economic benefit to the regional economy would be insubstantial; the cumulative effect of any of the alternatives would be a minimal change to any of the economic parameters.

Local effects would vary considerably, particularly in communities with transit stations. However, cumulative impacts even at the local level would be minimal because new residential development under the Build Alternatives would represent only a small fraction of total households in each municipality.

Table 5.4-9 Cumulative Impacts to the Economy in 2035

Historical Trend Affecting the Economy	Trends and Current or Future Actions Affecting the Economy	Economic Conditions in 2035				New Tax Receipts (2030)*	
		Alternative	Population	Jobs	Economic Activity (2030)*	Municipal	State
Recent growth in economic activity but slower growth in job market; geographic differences north-to-south	Global economic downturn; planned commercial and industrial developments in Southern Triangle 380,000 current jobs with 1.4 % per year growth	No-Build	928,031	417,864	$99B	N/A	N/A
		Build Alternatives					
		Scenario 1	935,041	419,205	$99.479B	$8.5-9.5M	$16-18M
		Scenario 2	935,036	419,203	$99.479B	$8.5-9.5M	$16-18M

* The Corridor Plan only includes projections through 2030.

5.4.9 SUMMARY OF CUMULATIVE IMPACTS

Table 5.4-10 summarizes the incremental changes to the evaluated resources from the South Coast Rail alternatives that, in combination with past activities or trends and other known current and future projects, would potentially result in a substantive cumulative effect. The comparison is provided for both scenarios for the three alternatives considered in this evaluation, in relationship to the status of these resources under the projected No-Build Alternative conditions in 2035. Because there is no substantive difference between the impacts from Build Alternatives' electric- or diesel-powered trains, these options are not included in this summary comparison.

Table 5.4-10 Summary of Incremental Cumulative Changes between Alternatives

	Resource					
	Land Use	Wetlands	Biodiversity	Protected Open Space	Air Quality	Economy
No-Build Alternative	Conversion of 1,315 acres per year	No net loss policy	22 acres of land converted per day	Protected at average rate of 383.7 acres per year	Trend of increasing GHG emissions counteracted by new regulatory requirements	Population: 928,031
	308,371 acres of undeveloped land remaining in 2035	Mitigation ratios of 1:1 to 3:1	116,675 acres of decreased habitat quality in 2035	64,795 acres of open space remaining in 2035	CO_2-equivalent emissions to be 80% of 1990 levels by 2050	Households: 75,212
		124,748 acres of wetlands remaining in 2035	307,813 acres of natural land remaining in 2035		28,691,855 tpy CO_2 emissions in 2035	Jobs: 417,864 Business Activity: $99B Tax Revenue: N/A
Stoughton Alternative Scenario 1	Conversion of 1,315 acres per year	No net loss policy	22 acres of land converted per day	Protected at average rate of 383.7 acres per year	Trend of increasing GHG emissions counteracted by new regulatory requirements	Population: 935,040
	307,030 acres of undeveloped land remaining in 2035	Mitigation ratios of 1:1 to 3:1	120,605 acres of decreased habitat quality in 2035	64,794 acres of open space remaining in 2035	CO_2-equivalent emissions to be 80% of 1990 levels by 2050	Households: 78,016
		124,756 acres of wetlands remaining in 2035	303,883 acres of natural land remaining in 2035		27,842,309 tpy CO_2 emissions in 2035	Jobs: 419,206 Business Activity: $99.5B Tax Revenue: +$8.5-9.5M (municipal) +$16-18M (state)
Whittenton Alternative Scenario 1	Conversion of 1,315 acres per year	No net loss policy	22 acres of land converted per day	Protected at average rate of 383.7 acres per year	Trend of increasing GHG emissions counteracted by new regulatory requirements	Population: 935,040
	307,045 acres of undeveloped land remaining in 2035	Mitigation ratios of 1:1 to 3:1	120,595 acres of decreased habitat quality in 2035	64,795 acres of open space remaining in 2035	CO_2-equivalent emissions to be 80% of 1990 levels	Households: 78,016

	Resource					
	Land Use	Wetlands	Biodiversity	Protected Open Space	Air Quality	Economy
Stoughton Alternative Scenario 2					by 2050	
Stoughton Alternative Scenario 2		124,754 acres of wetlands remaining in 2035	303,893 acres of natural land remaining in 2035		27,842,309 tpy CO_2 emissions in 2035	Jobs: 419,206 Business Activity: $99.5B Tax Revenue: +$8.5-9.5M (municipal) +$16-18M (state)
Stoughton Alternative Scenario 2	Conversion of 1,315 acres per year	No net loss policy	22 acres of land converted per day	Protected at average rate of 383.7 acres per year	Trend of increasing GHG emissions counteracted by new regulatory requirements	Population: 935,040
	315,583 to 319,259 acres of undeveloped land remaining in 2035	Mitigation ratios of 1:1 to 3:1	58,760 to 75,021 acres of decreased habitat quality in 2035	>64,794 acres of open space remaining in 2035	CO_2-equivalent emissions to be 80% of 1990 levels by 2050	Households: 78,016
		124,759 to 124,760 acres of wetlands remaining in 2035	349,467 to 365,728 acres of natural land remaining in 2035		<27,842,309 tpy CO_2 emissions in 2035	Jobs: 419,206 Business Activity: $99.5B Tax Revenue: +$8.5-9.5M (municipal) +$16-18M (state)
Whittenton Alternative **Scenario 2**	Conversion of 1,315 acres per year	No net loss policy	22 acres of land converted per day	Protected at average rate of 383.7 acres per year	Trend of increasing GHG emissions counteracted by new regulatory requirements	Population: 935,040
	315,598 to 319,274 acres of undeveloped land remaining in 2035	Mitigation ratios of 1:1 to 3:1	58,750 to 75,011 acres of decreased habitat quality in 2035	>64,795 acres of open space remaining in 2035	CO_2-equivalent emissions to be 80% of 1990 levels by 2050	Households: 78,016

	Resource					
	Land Use	Wetlands	Biodiversity	Protected Open Space	Air Quality	Economy
		124,757 to 124,758 acres of wetlands remaining in 2035	349,477 to 365,738 acres of natural land remaining in 2035		<27,842,309 tpy CO_2 emissions in 2035	Jobs: 419,206 Business Activity: $99.5B Tax Revenue: +$8.5-9.5M (municipal) +$16-18M (state)

Table 5.4-10 shows that, in comparison to the No-Build Alternative, the Stoughton and Whittenton Alternatives would not have an adverse cumulative impact on the evaluated resources. There would be only minor differences in the cumulative effects of the Stoughton and Whittenton Alternatives, attributable to the minor differences in direct effects. For many resources, the cumulative impacts of Scenario 1 represent an insubstantial change from the conditions that would exist under the No-Build Alternative. In general, the cumulative effects of either alternative would be beneficial, depending on the extent of implementation of Smart Growth measures.

5.5 IMPLEMENTATION OF THE SOUTH COAST RAIL ECONOMIC DEVELOPMENT AND LAND USE CORRIDOR PLAN

This section of the FEIS/FEIR was prepared in response to comments on the DEIS/DEIR in regard to the South Coast Rail Long-Term Smart Growth Evaluation and Environmental Stewardship Plan. The Secretary's Certificate directed MassDOT to consult with the Interagency Coordinating Group (ICG) to develop a long-term evaluation and monitoring plan for the anticipated environmental and smart growth benefits of the South Coast Rail project. Specifically, the Secretary's Certificate stated that MassDOT should explore existing models and performance metrics used to evaluate the effectiveness of smart growth plans and environmental protection strategies, and include a summary in the FEIR of experience from other regions that may be useful to apply in the case of this project. In addition, the Secretary's Certificate directed MassDOT to work with the Massachusetts Executive Office of EEA, the ICG, RPAs, and local communities to develop evaluation indicators and metrics tailored to the South Coast Rail project. The Secretary's Certificate required the FEIR to propose a mechanism for periodic reporting out to the public and other agencies on MassDOT's progress in achieving smart growth and environmental goals of the project, including its commitments to protection of ecologically significant habitat.

This section provides MassDOT's literature review of smart growth monitoring and indicators/metrics, proposes a series of smart growth performance metrics appropriate for the South Coast Rail Corridor Plan and a method for reporting out on the performance metrics for the long-term term plan. Note that the implementation of the Corridor Plan is not required by the USACE.

5.5.1 Literature Review

As directed in the Secretary's Certificate on the DEIS/DEIR for the South Coast Rail project, existing plans smart growth and monitoring programs from across the United States were identified and reviewed for applicability to the proposed project. The purpose of the review was to identify metrics or indicators that may be used to evaluate implementation of the Corridor Plan with respect to PDAs, the PPAs, and the Station Areas. A total of five existing plans/programs were reviewed; three in depth including interviews, and two based on a review of existing, readily available materials. Detailed information on the plans/programs reviewed is provided in Appendix 5.5-A.

A significant difference between the plans and programs review and the South Coast Rail project is that there is no legislative mandate in Massachusetts that controls growth through the planning process. However, this does not mean that the goals and objectives of the Corridor Plan cannot be implemented; only that participation by the local communities would be voluntary rather than compulsory. Data collection to support the metrics and indicators would be accomplished through cooperation between state agencies, RPAs, and local governments.

A number of commonalities were evident in the literature review and subsequent interviews. Data were typically collected every two years. In the case of SANDAG's RCP monitoring, the SANDAG staff had begun by collecting and reporting data every year. Collecting and reporting on the RCP progress every year became an extremely staff- and time-intensive task prompting SANDAG to revise the reporting timeframe to every two years. As noted by other interviewees, reporting every year will not show any major trends. Change happens slowly and therefore, the performance metrics or evaluation indicators chosen should be descriptive without being overly complicated or too simplified. A number of well-developed metrics or indicators under a high level category may be needed to describe trends as illustrated by the large number of measures used by SANDAG and the PSRC for their VISION 2040.

Many of the metrics and indicators reviewed are simple metrics that could be reported with numbers. Others are more complex to report. Through the interviews completed, it was clear that metrics and indicators that reveal the performance trends without being too complex or overly simplistic are ideal. Similarly, data that are readily available is the simplest way to track metrics and indicators. The U.S. Census Bureau was often used due to the large amounts of data that are collected. In the case of the San Diego's Regional Comprehensive Plan and the Puget Sound Regional Council's VISION 2040 and Growing Transit Communities, the RPAs were the source of the data used to fulfill the metric or indicator. Other government agencies, and in very few cases, independent entities outside of the government, supplied data as well.

5.5.2 Performance Metrics

5.5.2.1 Methodology

To develop the performance metrics, MassDOT reviewed the *Corridor Plan*, the Secretary's Certificate and comments on the South Coast DEIS/DEIR relevant to smart growth, and Executive Order 525. Through internet searches, MassDOT identified regional plans and implementation reports/performance metrics that had similarities to the smart growth development goals envisioned for the South Coast region. Interviews were conducted with the RPAs charged with the implementation and reporting of performance metrics.

- Performance metrics were reviewed and prioritized using the following criteria:
- Performance metrics that were specifically identified in the Secretary's Certificate.
- Applicability of performance metrics to the smart growth goals and strategies identified in the *Corridor Plan*.
- Ease and availability of data for regular data collection. With a few exceptions, performance metrics with identifiable data sources were included such as U.S. Census data.
- Screening and the identification of additional performance metrics with the RPAs and state agencies that would be responsible for the tracking and monitoring component of this program.
- Screening and the identification of additional performance metrics from the ICG Smart Growth Working Group.

- Verification and alignment of performance metrics with data already collected under Executive Order 525 by state and RPAs.

- Directly or indirectly attributable to the successful implementation of the *Corridor Plan.*

After performance metrics were identified and refined, a plan for monitoring and reporting the metrics was drafted. The Evaluation Plan identifies the agencies responsible for data collection and reporting as well as recommendations on the distribution/reporting to the public to document Smart Growth progress within the South Coast region as a result of the implementation of the *Corridor Plan*.

The performance metrics identified in this Evaluation Plan are those that can be directly or indirectly attributable to the successful implementation of the *Corridor Plan* and not to the addition of South Coast Rail to the region. Performance metrics related to the South Coast Rail project as a whole were considered, but ultimately not included in the Evaluation Plan. For example, the potential economic benefits of the South Coast Rail project to the region are well-documented in the FEIS/FEIR and the project is projected to bring increased economic activity and access to new jobs. However, these economic benefits are not in themselves attributable to smart growth development and could be anticipated as a result of the South Coast Rail project with or without smart growth. The Evaluation Plan does include an employment-related performance metric but it is focused on TOD because it reports on the jobs within 0.5 mile of a transit station.

5.5.2.2 South Coast Rail Corridor Plan Performance Metrics

The performance metrics developed for the South Coast Rail project include metrics under a number of categories as described further below. According to the Secretary's Certificate, "the evaluation plan should include a monitoring component to assess the accuracy of impact projections and allow for mid-course corrections and adaptive strategies as needed." The performance metrics associated with impacts are Metrics 2 through 5 in Table 5.5-1.

EIS/EIR and General Metrics

According to the Secretary's Certificate, "the evaluation plan should include a monitoring component to assess the accuracy of impacts projections and allow for mid-course corrections and adaptive strategies as needed." These metrics assess impacts such as growth projections, as well as forestland, farmland and wetland impacts that were projected in the FEIR/FEIS for the business-as-usual and smart-growth scenarios with the actual impacts to these resources. The impacts associated with these scenarios would vary depending on the level of implementation of the *Corridor Plan*. The Evaluation Plan compares predicted impacts with actual impacts to assess the success of the *Corridor Plan*. MassDOT would collect data so that it may notify other state agencies and municipalities that have the ability to make "corrections and adaptive strategies" as required by the Secretary's Certificate.

Priority Development Area Metrics

PDA performance metrics are applicable to encouraging growth and higher density development in the 33 PDAs identified in the *Corridor Plan*. There is also one combined PDA/PPA. The PDAs are areas with the greatest capability or potential to accommodate new development, including downtowns, major job centers, and future South Coast Rail station areas. These metrics gauge the results of the *Corridor Plan* on PDAs, such as state investments in infrastructure with PDAs and development density within PDAs.

Transit Oriented Development Metrics

Transportation Oriented Development metrics are applicable to encouraging appropriate development, as well as bicycle and pedestrian infrastructure within the planned Station Areas and within up to 0.5 to 1 mile radius of the station. TOD emphasizes "compact, generally mixed-use development at or near transit stops whose design encourages walking and transit use."[80] The boundary for a TOD district is generally defined to be within 0.25 to 0.5 mile of the Transit Station.[81] The South Coast Rail metrics for TOD are generally defined as within 0.5 mile of a station.

Conservation and Priority Preservation Area Metrics

The Conservation and PPA Metrics are applicable to monitoring the permanent preservation of land within the 72 PPAs (in addition, there is one combined PDA/PPA). PPAs include land or environmental resources that are not permanently protected but are worthy of increased levels of protection through planning, regulation, conservation or acquisition.

Social Equity Metrics

These metrics would be used to monitor the social equity benefits of the *Corridor Plan*. The *Corridor Plan* specifically mentions the Chapter 40B and inclusionary zoning as possible tools that municipalities can use to implement housing-related regulatory policies to direct development towards PDAs. The performance metrics are focused on the provision and planning of affordable housing within PDAs and station areas because it is assumed that the availability of affordable housing near station areas will result in increased access to jobs, medical care, and educational opportunities for low to medium income households. In addition, the provision of affordable housing will also help to moderate the effects of gentrification close to station areas. It should be noted that these metrics are focused on the success of the Corridor Plan to advance social equity, and not on the effects of new public transit services which are also expected to provide benefits to under-served minority and low-income populations.

5.5.2.3 Performance Metrics Data Collection

Performance metric data sources should be readily available data and, if possible, data that is already routinely collected. As such, the data sources for the South Coast Rail performance metrics include the South Coast municipalities, the U.S. Census Bureau, the Massachusetts Executive Office of Administration and Finance (A&F) Database, and the MassGIS. Executive Order 525, which directed state agencies to make infrastructure and land protection investments consistent with the priority areas identified on the Corridor Map of the *Corridor Plan*, directed the Massachusetts Office of Administration and Finance to develop a web-based tracking tool, the Administration and Finance Database, which would track state agency investment in the South Coast region related to the goals identified in the *Corridor Plan*. Finally, MassGIS data has readily available state-wide GIS data that can be used in GIS-based analyses to document changes throughout the South Coast region.

While the majority of the performance metrics are available through reliable and regularly updated data sources, there are a number of exceptions to these including:

- Metric 2 - Actual and predicted loss of farmland by community;

---

[80] Commonwealth of Massachusetts. South Coast Rail Economic Development and Land Use Corridor Plan. June 2009.
[81] Transit Cooperative Research Program. Transit-Oriented Development and Joint Development in the United States: A Literature Review. Number 52. October 2002.

- Metric 3 - Actual and predicted loss of wetlands by community; and
- Metric 4 - Actual and predicted loss of forestland by community.

There data were specifically requested by MEPA. Data for these metrics would be provided by MassGIS, however, the last updated GIS data were provided in 2004. Although it is not known when the GIS data would be updated, these metrics are included in the anticipation that the data would become available at some point during the 20-year monitoring period.

In addition to the MassGIS data, the VMT data, jobs, and housing and transportation affordability metrics are not currently regularly available for the South Coast region. These metrics include:

- Metric 5 - VMT for entire South Coast Region;
- Metric 21 - VMT per capita within 1 mile of station;
- Metric 22 - Total jobs within a 0.5 mile of station; and
- Metric 31 - Percent of household income spent on housing and transportation within 0.5 mile of station compared to region.

MAPC is currently working on a project to estimate annual mileage for every vehicle in the state, based on odometer readings during annual safety inspections, and to geocode the vehicles based on their registration address, and estimate fuel consumption and associated cost for each vehicle based on the mileage and EPA fuel efficiency ratings. The final product will be a “VMT Atlas.” MAPC has noted that these data could be available for the South Coast region and for station areas but that funding is not yet available to update the data on a regular basis.

Metrics 22 and 31 are currently proposed to be collected through the Center for Neighborhood Technology’s Transit Oriented Development Database (TOD database). CNT has developed the TOD database—a GIS platform that includes every fixed-guideway transit system in the United States and demographic and land use data for the half-mile radius around all 4,000 stations. This tool provides detailed information on the performance of TOD in metropolitan regions. The South Coast Region is not currently covered in the CTOD TOD database because these stations have not yet been constructed. Data collected for Metrics 22 and 31 using the TOD database are contingent on whether these stations and relevant data sources are added to the TOD database.

Although it is not confirmed that the data sources for these performance metrics would be regularly available, these metrics are included because there are no other readily available data sources for these metrics and they were noted to be of particular importance by the ICG Smart Growth Working Group.

Table 5.5-1 includes the proposed metric by title, the potential data sources, and suggested frequency of data collection based on the data source and ease of collection. These metrics were reviewed by the ICG Smart Growth Working Group (Executive Office of Housing and Urban Development, Massachusetts [EOHED], EPA, MassDEP, Executive Office of EEA, MEPA, USACE, and MassDOT) at meetings on April 26 and June 27, 2012, and revised based on the group’s feedback.

Table 5.5-1 South Coast Rail Proposed Performance Metrics

Topic	Indicator	Data Source	Frequency of Data Collection
EIS/EIR and General Metrics	1. Actual and predicted growth in the number of households by community	American Community Survey 5-Year Estimates at the Block Group Level	3 year
	2. Actual and predicted loss of farmland by community	MassGIS (as available)	3 year
	3. Actual and predicted loss of wetlands by community[1]	Local Conservation Commission agents, MassGIS (as available) and baseline, business-as-usual, and smart-growth scenarios from FEIR/FEIS and MassGIS	3 year
	4. Actual and predicted loss of forestland by community	MassGIS (as available)	3 year
	5. Vehicle miles travelled (VMT) for entire South Coast Region	MAPC (as available)	3 year
	6. State technical assistance to communities to implement *Corridor Plan* in dollars and type by community	A&F Spreadsheet	Annual
	7. Transfer of Development Rights (TDR) projects by municipality	Municipality	3 year
Priority Development Area Metrics	8. Housing units per acre within PDAs versus new housing units per acre outside of PDAs	American Community Survey 5-Year Estimates at the Block Group Level3	3 year
	9. New commercial/industrial square footage meeting or exceeding 10,000 sq. ft. in the PDAS and Commercial /Industrial square footage meeting or exceeding 10,000 sq. ft. outside PDAs in the South Coast Region[1]	A& F Spreadsheet3	Annual
	10. Type of new housing units located in PDAs: multi-family versus single family	American Community Survey 5-Year Estimates at the Block Group Level 3	3 year
	11. Number of municipalities with zoning revisions and type of zoning revisions supporting PDAs	A&F Spreadsheet4	3 year
	12. Permitting changes, such as expedited permitting under Chapter 43D, within PDAs	A&F Spreadsheet4	Annual
	13. Direct state investments and funding in PDAs (dollars)	A&F Spreadsheet3	Annual
	14. New state buildings and office leases in PDAs	A&F Spreadsheet3	Annual

Topic	Indicator	Data Source	Frequency of Data Collection
Transit Oriented Development Metrics	15. Number of municipalities that have adopted specific station area plans or have specific station area plans under development (total by municipality)	Municipality3	3 year
	16. Number of municipalities adopting parking management strategies within 0.5 mile of station	Municipality3	3 year
	17. Amount of new bike lanes provided by municipality	MassDOT and/or municipality	3 year
	18. Household density within 0.5 mile of station	Decennial U.S. Census and/or building permit data from municipality	10 year for decennial Census; 3 year for building permit data
	19. Mode share of commute to work within 0.5 mile of station	American Community Survey 5-Year Estimates at the Block Group Level	3 year
	20. Number of buildings that are LEED-Certified, developments using green building strategies and LEED for Neighborhood development Certified neighborhoods within Station Areas	U.S. Green Building Council, MAPC, Municipality[3]	3 year
	21. Vehicle-miles traveled (VMT) per capita within 1 mile of station	MAPC (as available)3	3 year
	22. Total jobs within 0.5 mile of Station	CNT TOD Database (as available). http://toddata.cnt.org/ Data derived from LED Work Area Characteristics.	3 year
Conservation and Priority Preservation Area Metrics	23. Number of municipalities creating open space plans and/or revising zoning ordinances to support PPAs (conservation subdivision bylaws such as cluster development or open space residential design bylaws) and how	Municipality (A&F Spreadsheet)4	3 year
	24. Number of land preservation projects by community	Municipality (A&F Spreadsheet)	3 year
	25. Percent and acreage of PPAs permanently protected	Executive Office of EEA	Annual
	26. Percent and acreage of PPAs developed	Executive Office of EEA	Annual
	27. Land preservation investment in PPAs	Executive Office of EEA	Annual

5.5.3 Monitoring and Reporting Program

This section describes MassDOT's proposed monitoring program for the *Corridor Plan* including the responsibilities for each state agency and RPA. The reporting program is also described in this section.

5.5.3.1 Current Monitoring Program

Currently Executive Order 525, described in Appendix 5.5-A, mandates policy commitments made in the *Corridor Plan* for "Strategic Investments" by committing the Commonwealth to use its discretionary grant funds and its investments to target technical assistance and infrastructure investments to priority areas, to the maximum extent feasible. The state programs that are under the purview of the Executive Order 525 are identified below according to responsibilities.

EOHED:

- MassWorks Grants
- Chapter 43D Expedited Permitting
- Brownfields Revolving Fund

Executive Office of Administration and Finance (A&F)/Department of Revenue (DOR)

- Brownfields Tax Credit
- Historic Tax Credit

Department of Housing and Community Development (DHCD):

- Economic Development Fund (component of the Community Development Block Grant Program)
- Economic Development Incentive Program
- Chapter 40R smart growth districts
- Chapter 40B housing developments
- Rental Round Assistance
- Housing Development Incentive Program

Division of Capital Asset Management (DCAM):

- Construction of new state buildings and new office leases

Executive Office of Energy and Environmental Affairs (Executive Office of EEA):

- Gateway City Parks
- PARC (formerly, Urban Self-Help)

- LAND (formerly, Self-Help)
- Land preservation programs at the Department of Fish and Game, Department of Agricultural Resources (Agricultural Preservation Restriction Program), Department of Conservation and Recreation, and Department of Environmental Protection
- Conservation Restrictions
- State Revolving Fund- clean and drinking water projects

MassDOT:

- Transportation Improvement Program projects
- Accelerated Bridge Program
- Non-Federal Aid transportation projects

MassDOT/EOHED:

- South Coast Rail Technical Assistance Program

The Executive Order requires annual reporting by directing A&F to develop a retrospective analysis to measure the consistency of state investment commitments with the *Corridor Plan* in addition to web-based tracking tool.[82] Over 245 state investment commitments, made between Fiscal year 2009 and Fiscal year 2011 in the South Coast Region, were reviewed as part of A&F's retrospective analysis.

As noted in the *Retrospective Report*[83], agencies have undertaken the following implementation actions to ensure compliance:

- Developing a strategic plan, by agency, for implementing the Executive Order, which will include considerations and issues raised in this report;
- Collecting data to report the implementation of the Executive Order by agency, which will be summarized in an annual report;
- Seeking approval from other agencies for investments that are inconsistent with the *Corridor Plan* (for example, the Executive Office of EEA would need to justify an exception to the EO 525 for land conservation in a PDA); and
- Targeting technical assistance and infrastructure investments to priority areas, to the maximum extent feasible.

In addition to the *Retrospective Report* and web based tracking tool, the Executive Order also directed A&F to collect and report state investment commitments each year in the region. These commitments

[82] Available online at: http://www.mass.gov/hed/economic/eohed/pro/planning/southcoast/executive-order-525/.
[83] South Coast Rail Inter-Agency Working Group. State Investment in the South Coast Region and Implementation of the Corridor Plan: A Retrospective Analysis. February 23, 2012.

will be used to measure consistency with the *Corridor Plan.* The first annual analysis will be released in Fall 2012.

5.5.3.2 Proposed Monitoring Program

The following sections describe the proposed monitoring and data collection responsibilities of the RPAs and the state agencies as well as the data collection administration by MassDOT. The first year of data collection would commence during the first year of construction of South Coast Rail as a baseline. Annual data collection would occur annually for state agencies and every three years for regional planning for the next 20 years provided that data are available. The state agencies would collect data annually as most of the data they collect is already collected annually as directed by EO 525 through the A&F spreadsheet. The initial data collection would be a significant effort on the part of the RPAs and state agencies**.** Therefore, MassDOT would identify funding to offset the cost.

MassDOT will request data from the RPAs annually and from A&F annually, after the data tracking has been completed and finalized each year. The RPAs' role will be to collect the necessary data from the South Coast Rail communities and other data sources such as the U.S. Census to provide to MassDOT. The RPAs are better suited to collecting data from municipalities and U.S. Census sources because of their expertise in planning research methods and their working relationships with the respective municipalities. Where applicable, data collected from the RPAs for each metric would then be aggregated by MassDOT. Municipal data collected by each of the RPAs would need to be aggregated to provide one metric for all South Coast Rail communities where applicable; however, the performance metrics would also include the metric by individual municipality and/or station area where applicable.

5.5.3.3 Regional Planning Agencies

The three RPAs (SRPEDD, MAPC, and OCPC) would be responsible for collecting the metrics which describe the South Coast region communities.

As described above, data collection would be a relatively intensive effort during the three years following the start of construction. Following the first three years, data would be collected every three years. Most of the raw data would require further manipulation since these data are input at the community-wide scale and do not distinguish projects within PPAs, PDAs, or station areas. Funding would be available to offset the cost. The RPAs would be responsible for data collection for the 20 performance metrics including:

- Metric 1: Actual and predicted growth in the number of households by community
- Metric 5: VMT for entire South Coast Region (MAPC)
- Metric 7: TDR projects by municipality
- Metric 8: Housing units per acre within PDA versus housing units per acre outside PDAs
- Metric 9: New commercial/industrial square footage meeting or exceeding 10,000 square feet in the PDAS and Commercial /Industrial square footage meeting or exceeding 10,000 square feet outside PDAs in the South Coast Region
- Metric 10: Type of new housing units located in PDAs: multifamily vs. single-family

- Metric 11: Number of municipalities with zoning revisions and type of zoning supporting PDAs
- Metric 12: Permitting changes, such as expedited permitting under Chapter 43D, within PDAs
- Metric 15: Number of municipalities that have adopted specific station area plans or have specific station area plans under development (total and by municipality)
- Metric 16: Number of municipalities adopting parking management strategies within 0.5 mile of station
- Metric 17: Amount of new bike lanes provided by municipalities
- Metric 18: Household density within 0.5 mile of station
- Metric 19: Mode share of commute to work within 0.5 mile of station
- Metric 20: Number of buildings that are LEED-Certified, developments using green building strategies and LEED for Neighborhood development Certified neighborhoods within Station Areas
- Metric 21: VMT per capita within 1 mile of station
- Metric 22: Total jobs within 0.5 mile of station
- Metric 23: Number of municipalities creating open space plans and/or revising zoning ordinances to support PPAs (conservation subdivision bylaws such as cluster development or open space residential design bylaws) and how
- Metric 24: Number of land preservation projects by community
- Metric 30: Percent of households spending greater than 30 percent of income on housing within 1 mile of Station
- Metric 31: Percent of income spent on housing and transportation within 0.5 mile of Station compared to region

5.5.3.4 State Agencies

Four state agencies are responsible to collect data in support of the metrics listed below. Those agencies include A&F, Executive Office of EEA, EOHED, and DHCD. These data would be collected annually because the majority of the data is already being collected annually through the A&F Spreadsheet. The data collection responsibilities are listed according to the state agency responsible.

Administration and Finance:

- Metric 6: State technical assistance to communities to implement Corridor Plan in dollars and type by community
- Metric 13: Direct state investments and funding in PDAs

- Metric 14: New state buildings and office leases within PDAs

Executive Office of Energy and Environmental Affairs:

- Metric 25: Percent and acreage of PPAs permanently protected
- Metric 26: Percent and acreage of PPAs developed
- Metric 27: Land preservation investment in PPAs including conservation restrictions and PARC (Self-Help), Gateway City Parks, LAND (Self-Help), land preservation programs by Department of Fish and Game and Department of Agricultural Resources; and Drinking Water State revolving fund

Executive Office of Housing and Economic Development:

- Metric 28: Number of housing production plans or housing master plans by municipality

Department of Housing and Community Development:

- Metric 29: Investment commitments targeted to Chapter 40B developments within PDAs

Department of Transportation

- Metric 2: Actual and predicted loss of farm land by community
- Metric 3: Actual and predicted loss of wetlands by community
- Metric 4: Actual and predicted loss of forestland by community

5.5.3.5 Reporting

As part of the monitoring and reporting program, MassDOT would be responsible for the reporting of results of performance metrics evaluation. MassDOT would draft a report, which would be published on MassDOT's website. The first report would be published approximately four years after the commencement of South Coast Rail Service. Subsequent reports would be available every three years after this first report, for a maximum of 20 years. The first report would include data collected for the baseline year (the first year of construction of South Coast Rail) and data collected three years of data after the baseline data collection year. Each subsequent report would include the historical data, as well as show data from the additional reporting period. The reporting schedule would be as shown in Figure 5-8.

Figure 5-8 Proposed Smart Growth Evaluation Plan Reporting Schedule

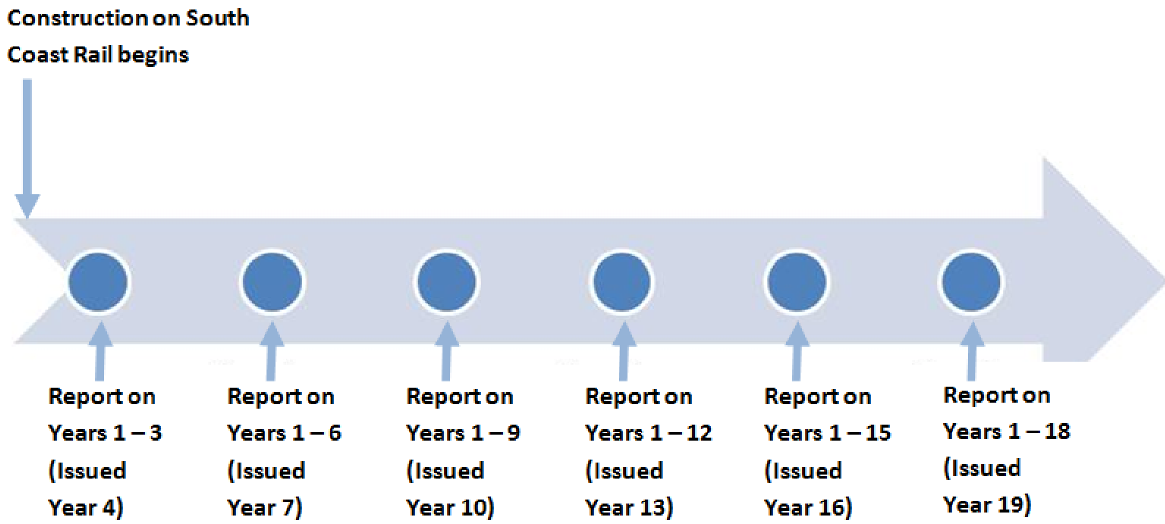

Table 5.5-2 demonstrates how each data point could be displayed (whether in a graph, chart, or table).

Table 5.5-2 Recommended Method of Reporting the Smart Growth Metrics to the Public on MassDOT's Website

Metric	Type	Representation	Additional Data Notes
1. Actual and predicted growth in the number of households by community	General	Table	Number of households per community for the reporting year compared to predicted. Total households would be reported in last row of table.
2. Actual and predicted loss of farm land by community	General	Table	Loss of acres of farmland by community for the reporting year compared to predicted. Total lost acreage would be on last row of table.
3. Actual and predicted loss of wetlands by community	General	Table	Loss of wetlands by community for the reporting year compared to predicted. Total wetland acreage lost would be on last row of table.
4. Actual and predicated loss of forest land by community	General	Table	Loss of forest land by community for the reporting year compared to predicted. Total forest land lost would be on last row of table.
5. VMT for entire South Coast region	General	Table	VMT for entire region for reporting year compared to what is predicted.
6. State technical assistance to communities to implement Corridor Plan in dollars and type by community	General	Table	Give dollar amount per community with a short description of project
7. Transfer of Development Rights project by community	General	Table	Description of each TDR project, including sending and receiving locations
8. Housing units per acre within PDA versus housing units per acre outside PDAs	PDA	Table	Table shows one row of data for housing units per acre within PDAs and one row showing housing units per acre outside PDA (the data is

Metric	Type	Representation	Additional Data Notes
			averaged for all municipalities)
9. New commercial/industrial square footage meeting or exceeding 10,000 sq. ft. in the PDAS and Commercial/ Industrial square footage meeting or exceeding 10,000 sq. ft. outside PDAs in the South Coast Region	PDA	Table	Table shows one row for data within PDA and one row for data outside PDA (the data is aggregated for all municipalities) for reporting year
10. Type of new housing units located in PDAs: multifamily vs. single-family	PDA	Table	Table shows one row for percent of multifamily and one row for single-family
11. Number of municipalities with zoning revisions and type of zoning supporting PDAs	PDA	Table	Number of municipalities with zoning revision in addition to a table which describes the type of zoning revisions by community. The table will also provide a column for the year that the zoning was adopted
12. Permitting changes, such as expedited permitting under Chapter 43D, within PDAs	PDA	Bar chart	Graph with one bar showing number of permitting changes (Chapter 43D) for PDA development and one bar showing percent of total expedited permitting changes for South Coast region
13. Direct state investments and funding in PDAs	PDA	Bar chart	Chart shows dollars in funding (y axis) by type of project (x axis) (MassWorks Infrastructure Program funding, Economic Development Fund, and Economic Development Incentive Fund, TIP projects, and Drinking Water State revolving fund)
14. New state buildings and office leases within PDAs	PDA	Table	Table has one line showing number of state buildings and number of office leases.

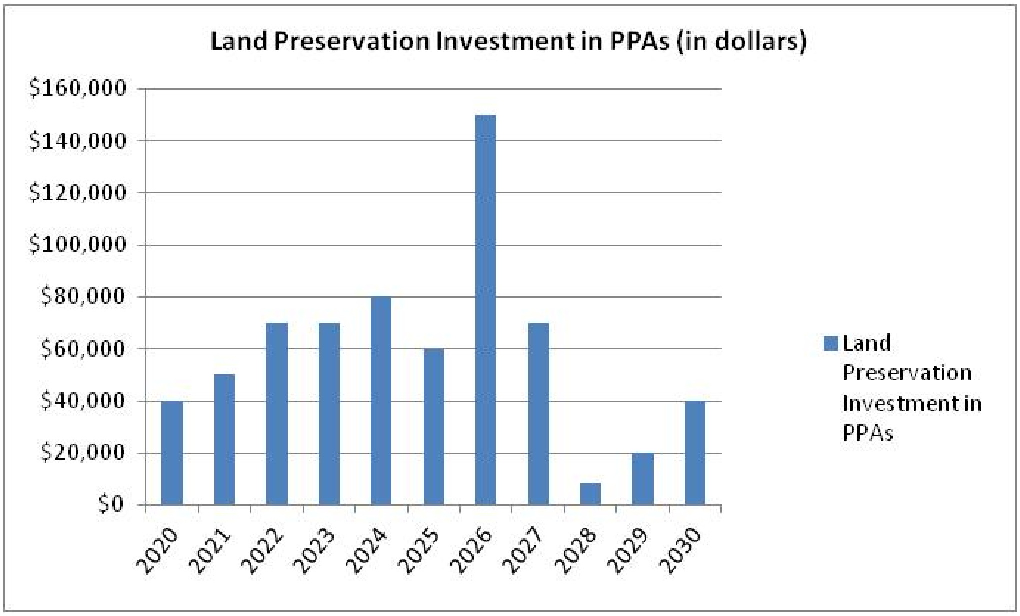
Community	Zoning Ordinance Supporting PDAs and Station Areas	Year	Status
Acushnet	Town creating a 40R district, to encourage mixed-income housing within PDA.	2025	In progress.
Fall River	City developed TOD zoning adjacent to the Station Area.	2024	Adopted May 10, 2024.
Freetown	SRPEDD worked with the city to develop TOD zoning beginning in fall 2009.	2024	Adopted April 20, 2024.
New Bedford	Developed specific area plans for station-area TOD for the Whale's Tooth and King's Highway station sites.	2023	Adopted April 10, 2023.
Taunton	Began developing a 40R district within a PDA.	2023	On hold.

Figure 5-9 Sample Metric 26. Land Preservation Investment in PPAs



Note: Land Preservation includes conservation restrictions and PARC (Self-Help), Gateway City Parks, LAND (Self-Help), land preservation programs by Department of Fish and Game and Department of Agricultural Resources; and Drinking Water State revolving fund.

5.5.4 Agency Coordination

The Secretary's Certificate specifically requested that MassDOT form a Working Group devoted to the implementation of the Corridor Plan. To meet this requirement, MassDOT convened the ICG Smart Growth Working Group, a subset of the ICG and included representatives from EPA, EOHED, Executive Office of EEA, MassDEP, and the RPAs. The purpose of the ICG Smart Growth Working Group was to develop evaluation indicators and metrics. In addition to the meetings described below, MassDOT worked closely with EOHED and SRPEDD staff to develop the range of metrics. MassDOT convened a meeting on April 16, 2012 with the Working Group, to present proposed performance metrics. Following the April meeting, MassDOT refined the performance metrics based on the feedback at that meeting and subsequent coordination with the RPAs and EOHED. The Smart Growth Work Group met again on June 27, 2012. At this meeting, MassDOT proposed a monitoring and evaluation plan to assess the accuracy of impact projections and allow for mid-course corrections and adaptive strategies as needed and performance metrics to evaluate the effectiveness of smart growth plans and environmental protection strategies.

6 COMMITMENT OF RESOURCES

6.1 INTRODUCTION

This chapter presents a discussion of the permanent commitment of resources of the South Coast Rail alternatives and an evaluation of the potential "costs" of consumption of environmental resources during the short-term construction phase of the South Coast Rail alternatives compared to the longer term productivity benefits associated with the operation of the South Coast Rail alternatives. In accordance with NEPA and the CEQ's implementing procedures under Title 40, Part 1502 of the Code of Federal Regulations, any EIS prepared pursuant to NEPA must include an analysis of both the relationship between short-term uses of the environment and the maintenance and enhancement of long-term productivity, and of any irreversible or irretrievable commitments of resources that would occur should the action be implemented (see 40 CFR 1502.16).

6.2 IRREVERSIBLE AND IRRETRIEVABLE COMMITMENT OF RESOURCES

6.2.1 Introduction

Resources that would be irreversibly and irretrievably committed to the South Coast Rail alternatives include funds, land, construction materials, energy and labor. However, based on social and economic studies undertaken for the analysis of potential impacts as a result of the South Coast Rail alternatives, these are not considered to be in limited supply. Thus, the use of such resources in the construction of the South Coast Rail alternatives would not adversely impact the availability of such resources for other projects both now and in the future.

Depending on the Build Alternative, it is estimated that expenditures for labor and materials during the construction phase would generate approximately 7,000 to 8,000 jobs for the Stoughton and Whittenton rail alternatives[1] (see Chapter 4.3, *Socioeconomics*). The use of labor for the construction of the proposed Build Alternatives would thus be a temporary benefit consistent with local, regional and state plans for the maintenance and expansion of employment opportunities in the South Coast region.

The Build Alternatives could also irreversibly and irretrievably alter visual resources, historic resources, open space, ACECs, farmland, plant, wildlife and fish communities and habitats and wetlands. The No-Build (Enhanced Bus) Alternative would also irreversibly and irretrievably commit funds, land, construction materials, energy and labor to maintain transportation facilities including rail facilities and the roadway network and to make limited improvements to existing Park and Ride facilities.

6.2.2 No-Build (Enhanced Bus) Alternative Irreversible and Irretrievable Commitment of Resources

The No-Build (Enhanced Bus) Alternative would result in an irreversible or irretrievable commitment of resources associated with maintenance and potential rehabilitation activities that could be taken over the short-term and long-term to address safety and level of service deficiencies of the existing transportation facilities. Maintenance of existing transportation facilities (rail and roadway) and rehabilitation of park-and-ride facilities and other improvements under the No-Build (Enhanced Bus)

[1] EOT. 2009. South Coast Rail Economic Development and Land Use Corridor Plan. Commonwealth of Massachusetts, Executive Office of Transportation and Public Works, and Executive Office of Housing and Economic Development. Prepared by Goody Clancy: Boston. Pg. 9.

Alternative would require commitments of construction materials, energy, labor and funds. Land use along the highway alignments is generally designated as transportation/utilities. These alignments would not change and no substantial new construction or land acquisition would be required for the No-Build (Enhanced Bus) Alternative.

Over the short-term, commitments of funds, materials, energy, land and labor under the No-Build Alternative would be less than those under the Build Alternatives because construction of the proposed project would not occur. However, over the long-term, energy use under the Build Alternatives will generally be lower than the No-Build Alternative because of improvements in transportation efficiency.

The cost of long-term transportation facilities maintenance under the No-Build Alternative compared to the Build Alternatives is uncertain. The Build Alternatives may make improvements to railroad infrastructure that would need to be maintained in the future. The No-Build Alternative may require more maintenance to compensate for the increased use of existing transportation facilities (rail or roadways) without the Build Alternatives.

6.2.3 Build Alternatives Irreversible and Irretrievable Commitment of Resources

6.2.3.1 Commitments of Funds

Federal funding has been provided for environmental review and Preliminary Engineering for the expansion of South Station and the selection of layover facilities in Boston and for the reconstruction of freight rail bridges in the New Bedford area. While the South Coast Rail project would utilize these facilities, these federally funded facilities have independent utility, as described in Chapter 3. To the extent that financial resources for construction would be provided through federal funds, local funds and/or private investments, such resources would not be available for other uses.

The commitment of financial resources would produce a one-time benefit to the local and regional economy through labor and capital expenditures for construction and, secondarily, through the flow of these monies within the local economy. These benefits would take the form of a temporary increase in demand for goods and services provided locally, earnings of local employees and jobs. (See Chapter 4.3, *Socioeconomics*). The long-term benefits of the project alternatives are described in the *South Coast Rail Economic Development and Land Use Corridor Plan.* The rail alternatives are anticipated to generate $448 million to $487 million in annual new business output by 2030.

Tax revenue losses are considered to be an irretrievable commitment associated with the Build Alternatives. Direct losses to the local governments as a result of the Build Alternatives include property tax payments that would be lost due to the acquisition of taxable properties within the proposed right-of-way. For most communities, with the exception of Fall River and New Bedford, the anticipated municipal property tax revenue loss would be on the order of 0.01 percent of their total municipal tax revenues. The Corridor Plan anticipates that property tax revenues will increase in cities and towns in the South Coast region, particularly in the areas around stations, due to the value added by new transportation access.

6.2.3.2 Commitments of Land

As described in Chapter 4.2, *Land Use and Zoning*, and Chapter 3, *Alternatives*, up to 136 acres of land (public and private) would be committed for the construction and operation of the proposed project. The land used in the construction of any of the Build Alternatives is considered to be an irreversible commitment during the time period that the land is used for construction and during the operational

periods. Should, however, a greater need arise for the use of the land, or should the proposed project no longer be needed, the land could be converted and committed to another use. However, there is no indication that such a need for conversion could develop or would be desirable.

6.2.3.3 Commitments of Energy and Materials

The Build Alternatives would require the use of various types of fossil fuels, electrical energy and other resources during construction and operation. These resources are considered to be irretrievably committed to the project. At this time, these resources are not in short supply and considered to be readily available to the Build Alternatives. As a result, the use of these resources is not expected to result in an adverse effect upon the continued availability of these resources.

The Build Alternatives would require the commitment of various types of construction materials, including steel, aggregate, cement, asphalt (bituminous materials), electrical supplies, piping and other raw materials such as metal, stone, sand and fill material. Additionally, large amounts of labor and natural resources would be committed to the fabrication and preparation of these construction materials. This commitment of resources is irretrievable but the resources are not in short supply and their use would not result in any adverse effect upon their continued availability. Much of the material accumulated for construction may at some time be recycled or used for fill or for some other use. In addition, to the greatest extent practicable, the Build Alternatives would use recycled building materials, thereby reducing the demand for new construction materials.

Development of the proposed alternatives and implementation of mitigation would result in a temporary increase in energy and fuel consumption during construction. The initial operation of the Build Alternatives may result in a slight increase in energy consumption when compared to the No-Build (Enhanced Bus) Alternative. However the Build Alternatives would be expected to result in a long-term decrease in energy consumption, through increased travel efficiency along new or improved transit routes (rail or bus) during operation.

6.2.3.4 Commitments of Labor

Depending on the Build Alternative, it is estimated that the construction phase would require the commitment of labor resources in the amount of approximately 7,000 to 8,000 jobs for the rail alternatives[2] (see Chapter 4.3, *Socioeconomics*). These workers will, by necessity, not be available for other projects during the construction period and should be considered as irretrievably committed to the proposed project.

6.3 RELATIONSHIP BETWEEN SHORT-TERM USES OF THE ENVIRONMENT AND THE MAINTENANCE AND ENHANCEMENT OF LONG-TERM PRODUCTIVITY

6.3.1 Introduction

NEPA requires the disclosure of the relationship between short-term uses of the environment and the maintenance and enhancement of long-term productivity, in other words, the tradeoffs between the potential adverse impacts of the proposed project and the potential long-term benefits of the proposed

[2] EOT. 2009. South Coast Rail Economic Development and Land Use Corridor Plan. Commonwealth of Massachusetts, Executive Office of Transportation and Public Works, and Executive Office of Housing and Economic Development. Prepared by Goody Clancy: Boston. Pg. 9.

project. This section defines “short-term” as being construction related and “long-term” as being the operational phase of the proposed project.

6.3.2 Short-term Uses

The No-Build Alternative would not require substantial construction and this would not result in any short term impacts. Short-term construction impacts of the build alternatives would be associated with the economics of affected and displaced businesses; traffic detours; pedestrian and bicycle access; noise and vibration; and air quality, including dust. The construction of the Build Alternatives would create economic benefits during construction, in the form of jobs and the direct and indirect demand for goods and services associated with construction activities (see Chapter 4.3, *Socioeconomics*).

The public transportation system between the South Coast region and Boston does not meet current and future regional transportation needs, as described in Chapter 2, *Purpose and Need*, Chapter 3, *Alternatives*, and Chapter 4.1, *Transportation*. If the Build Alternatives were not constructed, the transportation service provided by the existing transportation network between the South Coast region and Boston would continue to decline and demand for transportation would increasingly go unmet, both qualitatively and quantitatively.

The Build Alternatives would have greater impacts during the construction period than the No-Build Alternative. The environmental effects of the Build Alternatives are described in detail in Chapter 4, *Affected Environment and Environmental Consequences*, and Chapter 5, *Indirect Effects and Cumulative Impacts*. Depending on the alternative, adverse direct construction impacts may include residential and commercial displacements, disruption of existing traffic patterns, temporary noise and dust, and the disturbance of soils, vegetation, wildlife habitat, wetlands and open space. Most of the adverse impacts can be minimized through mitigation, as described in detail for each resource topic in Chapter 4 and summarized in Chapter 7, *Proposed Mitigation and MASSDOT Proposed Section 61 Findings*. Beneficial short-term construction impacts include economic benefits to the South Coast region through the generation of new employment and local expenditures.

6.3.3 Long-term Productivity

The operation of the Build Alternatives may have long-term adverse impacts including the encroachment/fragmentation of wildlife habitat, wetland filling, impacts on vegetation and open space, impacts on historic resources, impacts on visual resources, increased use of de-icing salts, minor increases in pollutant loadings to surface water bodies, and incompatibilities with local land uses and community character as a result of noise. Most of the adverse impacts can be mitigated or avoided, depending on the alternative. The alternatives themselves present trade-offs between the long-term productivity impacts on different resource categories.

The long-term benefits of the Build Alternatives include improved transportation access (both qualitative and quantitative) and enhanced access to important employment centers, educational and community facilities. The Build Alternatives would also contribute to improved safety conditions and air quality and reduction of Greenhouse Gas emissions, as described in Chapter 2, *Purpose and Need*, Chapter 3, *Alternatives*, Chapter 4.1, *Transportation*, Chapter 4.4, *Environmental Justice*, and Chapter 4.9, *Air Quality*.

In comparison to the short-term and long-term environmental consequences and mitigation, the operation of the Build Alternatives would contribute to the overall enhancement of the quality of life in

and throughout the South Coast region. The Build Alternatives would improve travel conditions and efficiency, thus contributing to long-term productivity.

Through the construction and operation of the Build Alternatives, the following improvements would occur:

- Improvement in availability of public transportation between the South Coast region and Boston.
- Improvement in the quality of transit service between the South Coast region and Boston, in terms of travel time and reliability.
- Reduction in VMT and reduced congestion. All Build Alternatives would result in a reduction of the number of miles driven by automobiles, as the Build Alternatives would induce commuters to travel by train or bus rather than drive between Boston and the South Coast region. Fewer cars on the road would ease congestion along highway corridors, resulting in time benefits.
- Improvement of air quality. The reduction in driving as a result of the Build Alternatives would reduce emissions of pollutants by mobile sources, thereby contributing to cleaner air.
- Reduction of Greenhouse Gas emissions. The reduction in driving as a result of the Build Alternatives would contribute to reduced emissions of CO_2 and other greenhouse gases.
- Improved safety conditions for motorists, bicyclists, pedestrians and school children along the main highway corridors and in the roadway network, as a result of reduced traffic congestion due to the Build Alternatives.
- Reduction in automobile related noise, due to reduction in automobile VMT.
- Enhanced regional mobility. In addition to improving access between the South Coast region and Boston, the Build Alternatives would also enhance mobility within the region by including interregional links that provide one-seat rides from one municipality to another.
- Improvement in access and travel time to jobs colleges, hospitals, and Boston for environmental justice populations in Fall River, New Bedford and Taunton, as described in Section 3.3.3.1 of Chapter 3, *Alternatives*.
- Smart Growth benefits. According to the South Coast Rail Economic Development and Land Use Corridor Plan,[3] commuter rail service to the South Coast would generate nearly $500 million in new economic activity every year. This is new growth by the year 2030 that would not occur without the new infrastructure. The rail connection is projected to create between 3,500 and 3,800 net new jobs within the Commonwealth by 2030—about two-thirds of which would locate in the South Coast region with the remaining third in Boston-Cambridge and other communities outside the region.

[3] EOT. 2009. South Coast Rail Economic Development and Land Use Corridor Plan. Commonwealth of Massachusetts, Executive Office of Transportation and Public Works, and Executive Office of Housing and Economic Development. Prepared by Goody Clancy. Boston.

The construction of the Build Alternatives would be phased and only portions of the project area would be committed as a construction site at any given time (see Section 3.2 of Chapter 3, *Alternatives*). Therefore, the land area to be used during the various construction phases is considered as a short-term use while during the operation of the proposed project this land area is considered to be a long-term use. The productivity of this land, in terms of its economic productivity in generating property and sales taxes, would be lost during this period and in the long-term, but may be recovered through the economic development predicted by the Corridor Plan.

The construction period will generate new productivity in terms of new construction related employment, new payrolls and purchases of materials, supplies and services. As a result of the proposed project, non-construction related employment would be generated temporarily during the period of construction, with the addition of new purchases both from construction related activity and the added expendable income resulting from the generated part-time and permanent employment.

Depending on the alternative, the long-term effect of the construction and operation of the proposed project would be to more fully meet the existing and future demand for public transportation between Fall River/New Bedford and Boston, Massachusetts to enhance regional mobility (see Chapter 2, *Purpose and Need*).

7 PROPOSED MITIGATION AND MASSDOT PROPOSED SECTION 61 FINDINGS

7.1 INTRODUCTION

The CEQ regulations for implementing the NEPA require an EIS to discuss means to mitigate adverse environmental impacts (40 CFR 1502.16(h) and 1502.14(f)).

In accordance with the NEPA regulations, this chapter identifies and evaluates measures that would avoid or minimize impacts. As summarized in this chapter and discussed in greater detail in Chapter 4, certain impacts to environmental resources are unavoidable. For those impacts measures that minimize adverse impacts have been identified. These measures are discussed at the end of each resource section in Chapter 4 and summarized in this chapter.

The MEPA regulations, at 301 CMR 11.07(j), outline mitigation measures to be addressed in the EIR process, including an "assessment of physical, biological and chemical measures and management techniques designed to limit negative environmental impacts or to cause positive environmental impacts during development and operation of a Project."

The Secretary's Certificate[1] on the DEIR for the South Coast Rail project included requirements for the scope of the FEIR. The Certificate required that the FEIR include:

- "Details on the proposed measures, roles and responsibilities, and MassDOT's commitments to implement specific measures to promote smart growth and achieve the mitigation and environmental benefits described in the DEIR/S. The FEIR should discuss the mitigation planning and outreach process conducted during FEIR preparation."

- "Revised Section 61 Findings for all state agency permits that reflect the detailed mitigation commitments to be provided in the FEIR. [Greenhouse gas] commitments and related self-certification language should be included in the draft Section 61 Findings for [Massachusetts Department of Environmental Protection] permitting."

- "A separate chapter on mitigation measures, which should include a summary table of all mitigation commitments as well as the revised Section 61 Findings. The Section 61 Findings should describe the proposed mitigation measures, contain clear commitments to mitigation and a schedule for implementation, and identify parties responsible for funding and implementing the mitigation measures. The draft Section 61 Findings will serve as the primary template for permit conditions. Final Section 61 Findings will be included with all state permits issued for this project and will include conditions considered binding upon the proponent as mitigation commitments."

This chapter (Section 7.4) provides a description of MassDOT's commitments to mitigation for impacts on each of the environmental and social resources identified in the Secretary's Certificate on the ENF, with summary table listings all of the mitigation commitments (Tables 7.5-1 and 7.5-2). MassDOT's proposed Section 61 Findings are included as Section 7.2.

[1] Executive Office of Energy and Environmental Affairs. *Certificate of the Secretary of Energy and Environmental Affairs on the Draft Environmental Impact Report/Statement, South Coast Rail Project*. June 29, 2011.

7.2 PROPOSED SECTION 61 FINDINGS

This section of this joint FEIS/FEIR was contributed by MassDOT, which is solely responsible for its content. The information contained in this section is pertinent to the FEIR only, pursuant to the proponents' responsibilities under the Massachusetts Environmental Policy Act. The U.S. Army Corps of Engineers is not a proponent, does not have a role in MEPA compliance and does not have a position with regard to the data contained herein.

Massachusetts General Law Chapter 30, Section 61 authorizes state agencies with permitting responsibilities to make an official determination regarding potential impacts from a proposed project and whether impacts have been avoided, minimized, and/or mitigated for appropriately. The Law requires agencies/authorities to issue a determination that includes a finding describing the environmental impact, if any, of the project and whether all feasible measures have been taken to avoid or minimize said impact.

This section provides a brief overview of the project, explains the history of the MEPA review process for the proposed South Coast Rail project, outlines required state and federal permits and their authorities, summarizes mitigation commitments for permanent and construction-related impacts, and provides draft Section 61 determination language for state agencies.

7.2.1 Project Description

The South Coast Rail project is an initiative of MassDOT and the MBTA to bring public transportation to the South Coast region that will increase access to transit for an underserved area of the state, increase transit ridership, improve regional air quality, reduce greenhouse gas emissions, and support opportunities for smart growth and economic development.

The restoration of passenger rail service to the South Coast region has been extensively studied for over 20 years. Prior to 1958, the Middleborough, Stoughton, and Attleboro rail lines were part of the Old Colony Railroad system that provided service to Fall River and New Bedford from Boston's South Station, via Canton Junction, along the Stoughton Branch railroad. Since discontinuation of this service, commuter rail has only been available to southeastern Massachusetts along the Boston-Providence Shore Line, with stops in Attleboro and South Attleboro, and the Old Colony Middleborough Line, which terminates in Lakeville. However, none of these provide an opportunity for commuters from the Fall River or New Bedford areas to easily or efficiently access rail transportation to Boston.

The MBTA has analyzed six alternatives for providing improved transportation between downtown Boston and the cities of Fall River and New Bedford. The three alternatives considered most viable were: (1) extending the existing MBTA Stoughton Line, (2) extending the existing MBTA Middleborough Line, and (3) providing new service, branching off from the Providence Line near Attleboro. A non-rail alternative, Rapid Bus, was also analyzed.

The Stoughton Alternatives would use existing active commuter and freight rail tracks (the Northeast Corridor, Stoughton Line, New Bedford Main Line, and Fall River Secondary) and a segment of out-of-service rail right-of-way (the Stoughton Line between Stoughton Station and Weir Junction in Taunton). Three existing commuter rail stations would be modified (Canton Junction, Canton Center, and Stoughton) and ten new stations constructed (North Easton, Easton Village, Raynham Place, Taunton, Taunton Depot, Freetown, Fall River Depot, Battleship Cove, King's Highway, and Whale's Tooth). The

South Coast Rail project also includes two overnight layover facilities, at the Weaver's Cove East site in Fall River and at the Wamsutta site in New Bedford.

MassDOT has identified the Stoughton Alternative as its Preferred Alternative and has not identified a preference between the Stoughton Electric and Stoughton Diesel Alternatives (see MassDOT's Preface to the FEIS/FEIR).

The South Coast Rail project also includes two overnight layover facilities, at the Weaver's Cove East site in Fall River and at the Wamsutta site in New Bedford.

The railway would consist of single track, with passing sidings as needed, to reduce wetland impacts. A trestle through the Hockomock Swamp ACEC would minimize impacts to wildlife habitat and rare species. Stations have been designed to minimize traffic impacts and land acquisitions.

7.2.2 History of MEPA Review

The restoration of passenger rail service to the South Coast region has been extensively studied for almost twenty years. Prior to 1958, the Middleborough, Stoughton (via the Whittenton Route), and Attleboro rail lines were part of the Old Colony Railroad System that provided service to Fall River and New Bedford from Boston's South Station, via Canton Junction, along the Stoughton Branch railroad. Since discontinuation of this service, commuter rail has only been available to southeastern Massachusetts along the Boston-Providence Shore Line, with stops in Attleboro and South Attleboro, and the Old Colony Middleborough Line, which terminates in Lakeville. However, none of these provide an opportunity for commuters from the Fall River or New Bedford areas to easily or efficiently access rail transportation to Boston.

In 2000, the MBTA completed a DEIR that analyzed six alternative routes for providing improved transportation between downtown Boston and the cities of Fall River and New Bedford. The DEIR focused on what were viewed then as the three most viable alternatives: (1) extending the existing MBTA Stoughton Line, (2) extending the existing MBTA Middleborough Line, and (3) providing new service, branching off from the Providence Line near Attleboro.

In 2002, a FEIR, submitted by the MBTA, concluded that extending the Stoughton Line was the most practicable and feasible of the alternatives and MassDOT received state-level approval from the Secretary of Environmental Affairs to proceed with planning for the South Coast Rail project as an extension of the existing Stoughton Line. On August 30, 2002, the MEPA Secretary issued a Final Certificate (Executive Office of EEA File # 10509) stating that the FEIR adequately and properly complied with MEPA and its implementing regulations. Due to the lapse of time, MassDOT has undertaken a new review under MEPA.

An ENF was submitted for review under MEPA on November 15, 2008. After public review, the Secretary of the Executive Office of EEA issued a Certificate on the ENF on April 2, 2009. The Certificate found that an Environmental Impact Report was required, and provided a detailed scope for that document.

As noted above, for the project to proceed to construction, it is necessary to obtain a Clean Water Act Section 404 permit from the Corps to authorize placement of dredged or fill material in "waters of the United States." Therefore, the USACE is conducting a review of the project under NEPA. A Notice of Intent to prepare an EIS was published in the Federal Register on October 31, 2008.

On March 23, 2011, the Notice of Availability for the South Coast Rail project DEIS/DEIR was published in the Environmental Monitor. The USEPA published a NEPA Notice of Availability in the Federal Register on March 25, 2011. After detailed review, on June 29, 2011 the Secretary issued a Certificate on the 2011 DEIR. The Secretary's Certificate stated that "I hereby determine that the Draft Environmental Impact Report/Statement (DEIR/S) submitted for this project adequately and properly complies with MEPA. The Proponent, the Massachusetts Department of Transportation (MassDOT) should submit a FEIR in accordance with the Scope below. As was the case with the DEIR/S, MassDOT may adopt the Final Environmental Impact Statement (FEIS), which is being prepared by the U.S. Army Corps of Engineers, as its FEIR and submit a combined Final EIR/EIS for MEPA review, as long as the FEIS meets the scope below." The Secretary's Certificate on the 2011 DEIR also stated that "I am satisfied that MassDOT has made the case for the Stoughton Route to be brought forward as the preferred alternative in the FEIR. …MassDOT did not identify a preferred mode among the diesel and electric alternatives. However, because the electric alternative is preferable from an air quality perspective, the Stoughton Electric [Alternative] should be the focus of the FEIR."

For the purpose of NEPA and Section 404(b) permitting, both the Stoughton and Whittenton Alternatives (electric and diesel versions) were evaluated in this FEIS/FEIR.

7.2.3 Related Permits and Approvals

In addition to compliance with the NEPA and the MEPA, a number of local, state, and federal permits are needed for the proposed project, as listed in Table 7.2-1.

Table 7.2-1 Required Permits and Approvals

Issuing Agency	Approval or Permit
U.S. Army Corps of Engineers	Clean Water Act, Section 404 Individual Permit
	Section 10 of the Rivers and Harbors Appropriation Act of 1899
U.S. Environmental Protection Agency Region I	National Pollutant Discharge Elimination System, Construction General Permit
U.S. Coast Guard	Section 9 of the Rivers and Harbors Appropriation Act of 1899
Massachusetts Office of Coastal Zone Management	Coastal Zone Management, Federal Consistency Determination
Massachusetts Executive Office of Energy and Environmental Affairs	Public Benefits Determination
Massachusetts Department of Environmental Protection	Massachusetts Wetlands Protection Act Variance
	Massachusetts Public Waterfront Act License(s) (Chapter 91)
	Clean Water Act, Section 401 Water Quality Certificate
	Section 61 Finding
Massachusetts Department of Fish and Game	Massachusetts Endangered Species Act Conservation and Management Permit
Massachusetts Historical Commission	Review of project for impacts to historic and archaeological properties and approval for compliance with M.G.L. Chapter 9, Sections 26-27C
	Memorandum of Agreement (with Corps and MassDOT)
	Section 61 Finding

7.2.4 Draft Section 61 Findings

Draft Section 61 Findings for the Project have been prepared by MassDOT to comply with the requirements of Massachusetts General Laws, Chapter 30, Section 61, and MEPA regulations at 301 CMR 11.07(6)(k), which require state agencies and authorities to review, evaluate, and determine the impacts on the natural environment of all projects or activities requiring permits issued by the state. State agencies are also asked to issue findings describing environmental impacts and to certify that all feasible measures have been taken by MassDOT to avoid or minimize these impacts. Section 61 Findings will be required from agencies with responsibilities for issuing the following permits, and from MassDOT for funding for the construction:

- Section 401 Water Quality Certification;
- Wetland Protection Act permit Variance;
- Massachusetts Endangered Species Act Conservation and Management Permit; and
- Massachusetts Public Waterfront Act (Chapter 91) License.
- Massachusetts Coastal Zone Management Consistency Determination

The italicized text in the following paragraphs is a proposed Section 61 Finding by MassDOT that extends to cover all potential impacts of the project.

Project Name:	*South Coast Rail*
Project Location:	*Fall River/New Bedford to Boston*
Project Proponent:	*Massachusetts Department of Transportation*
EOEA Number:	*14346*

The potential environmental impacts of the project have been characterized and quantified in the Final EIS/EIR, which are incorporated by reference into this Section 61 Finding. Throughout the planning and environmental review process, MassDOT has been working to develop measures to mitigate significant impacts of the proposed safety improvements. With the mitigation proposed and carried out in cooperation with state agencies, [Agency] finds that there are no significant unmitigated impacts.

MassDOT has prepared Tables of Mitigation (Tables 7.4-1, 7.5-1 and 7.5-2 of the FEIS/FEIR) that specify, for both temporary and permanent impacts, the mitigation that MassDOT will provide.

Therefore, [Agency] having reviewed the MEPA filings for the South Coast Rail Project, including the mitigation measures summarized in Chapter 7 of the FEIS/FEIR, finds pursuant to M.G.L. C. 30, §61 that, with the implementation of these mitigation measures, all practicable and feasible means and measures will have been taken to avoid or minimize potential damage from the project to the environment. In making this finding, [Agency] has considered reasonably foreseeable climate change impacts, including additional greenhouse gas emissions, and effects, such as predicted sea level rise.

7.3 AVOIDANCE AND MINIMIZATION

As described throughout this FEIS/FEIR, measures have been identified to avoid and minimize impacts, while meeting the transportation purpose and need of the project.

Chapter 3 describes the alternatives analysis process that resulted in selection of the Stoughton Alternative as the Preferred Alternative. This alternative best meets the project purpose and need balanced with a minimum of environmental impacts.

The Stoughton Alternative has been designed by MassDOT to avoid or minimize impacts to environmental and social resources. This alternative was developed to maximize the use of existing transportation infrastructure corridors, thereby avoiding or minimizing impacts to undeveloped lands and natural resources. Chapter 3 documents the iterative process of identifying sites for potential stations and layover facilities that sought to avoid impacts to wetlands, threatened and endangered species habitat, water resources, ACECs and open space, as well as to residential areas and businesses. The railway would consist of single track, with passing sidings as needed, to reduce wetland impacts. A trestle through the Hockomock Swamp ACEC would minimize impacts to wildlife habitat and rare species. Stations have been designed to minimize traffic impacts and land acquisitions.

MassDOT anticipates that additional measures to minimize unavoidable impacts would be undertaken during the preliminary and final design through (among other elements) the refined grading design of tracks and roadways, station layout, and the design of bridges and culverts to meet Massachusetts River and Stream Crossing Standards where feasible. Unavoidable impacts will be mitigated as described below.

7.4 PROJECT MITIGATION COMMITMENTS

The South Coast Rail Stoughton Alternative was developed to meet the critical transportation need of the Project, while recognizing the need to balance the Project's benefits with the direct and indirect impacts on natural resources, including the use of mitigation strategies. This has been an ongoing iterative process that will continue to identify and incorporate additional avoidance and minimization strategies through further, more detailed design, construction and operation. Some impacts to natural resources are unavoidable.

Pursuant to the USEPA Section 404(b)(1) Guidelines, the Corps of Engineers, in its Section 404 review, applies a 3-tiered approach in evaluating mitigation proposals. In conducting the 404(b), the Corps must ensure (1) avoidance of impacts to the aquatic environment to the maximum extent practicable; (2) minimization of impacts to the aquatic environment to the extent practicable and finally (3) compensatory mitigation of unavoidable aquatic resource losses. Further, the LEDPA determination is made independent of evaluation of mitigation.

MassDOT's mitigation commitments are consistent with the requirements for federal environmental review by the USACE. The level of detail at this stage of design is appropriate to support the environmental analysis, comparison of the No-Build and Build Alternatives, and development of conceptual mitigation measures. During preliminary and final design more detailed and specific mitigation measures and comparison of mitigation alternatives will be developed.

The following sections provide an overview and outline of the conceptual mitigation measures for impacts identified in Chapter 4 that would be developed as more specific, implementation-oriented

mitigation measures during preliminary and final design. The mitigation measures that MassDOT and MBTA have committed to are listed in Table 7.5-1 and 7.5-2 for permanent and construction impacts, respectively. The mitigation requirements described in the Secretary's Certificate on the 2011 DEIR are also listed; the mitigation requirements of the Secretary's Certificate on the 2008 ENF were provided in the 2011 DEIR and are not reiterated here.

7.4.1 Transportation

The Secretary's Certificate on the 2011 DEIR stated that the FEIR should

- Respond to the comments regarding traffic congestion and potential delays in emergency services and include details of any mitigation proposed.

Section 4.1.5 of this FEIS/FEIR provides an overview of the transportation mitigation measures that will be incorporated during preliminary and final design, and reviewed with the individual municipalities as part of the final design process. The proposed traffic mitigation measures include improvements to pedestrian facilities (crosswalks, sidewalks), roads (streets, signage, traffic signals), grade crossings (gates, signals), and coordinating with local emergency service providers during design. The specific locations where mitigation measures are proposed for transportation impacts are listed in Table 7.4-1, while the overall mitigation commitments are provided in Tables 7.5-1 and 7.5-2.

Table 7.4-1 Proposed Traffic Mitigation Measures near Stations

Station	Intersection/Roadway	Mitigation
North Easton Station	Route 138 at Roche Bros. Way	Revise signal timings
	Route 138 at Main St.	Revise signal timing, including longer pedestrian timings
	Route 138 at Elm St.	Widen Route 138 to provide two lanes northbound and southbound Install traffic signal
	Route 138 at Union St.	Widen Route 138 to provide two lanes northbound and southbound Install traffic signal
Easton Village Station	Route 138 at Belmont Street	Revise signal phasing and timings
	Main Street at Center Street/Lincoln Street	Install pavement marking and signage improvements
	Lincoln Street at Barrows Street	Install pavement marking and signage improvements
Raynham Park Station	Route 138 at Elm St.	Revise signal timing, including longer pedestrian timings
	Arlington Street at School Street	Re-align Robinson Street to create 4-way intersection Widen Route 138 to provide two lanes northbound and southbound Install traffic signal
Taunton Station	Broadway and Washington Street	Revise signal timing
	Dean Street at Longmeadow Street	Restripe Longmeadow Street to provide two southbound lanes Revise signal timing, including longer pedestrian timings
	Dean Street at Prospect Street	Install pavement marking and signage improvements

Station	Intersection/Roadway	Mitigation
	Dean Street at Arlington Street	Reconstruct traffic signal system based on new adjacent grade crossing equipment Widen Arlington Street to provide two southbound lanes
	Arlington Street at School Street	Convert to all-way stop
Taunton Depot Station	Route 140 at Hart Street	Revise signal timing
	Taunton Depot Drive	Construct sidewalk along the northern side of the Target Plaza parking lot to station area
King's Highway Station	King's Highway	Install signal interconnect infrastructure between Mount Pleasant Street and Church Street
	Mount Pleasant Street at Jones Road/ King's Highway	Revise signal phasing and timings
	King's Highway at Shaw's Drive	Improve signal equipment, phasing and timing to provide concurrent pedestrian crossing
	King's Highway at Stop & Shop Drive	Pre-empt grade crossing signals Reconfigure Stop & Shop Drive to accommodate diverted Tarkiln Hill Road traffic
	Tarkiln Hill Road at Church Street	Pre-empt grade crossing signal Revise signal timing , including longer pedestrian timings
Whale's Tooth Station	Acushnet Avenue at Hillman Street	Improve crosswalks and pedestrian ramps
	Acushnet Avenue	Construct approximately 300 feet of sidewalk along east side of Acushnet Avenue
	Mill Street at Pleasant Street and Kempton Street	Revise signal timing, including longer pedestrian timings
	Coggeshall Street at North Front Street	Install traffic signal
Freetown Station	South Main Street	Construct approximately 1,600 feet of sidewalk along the east side of South Main Street
	South Main Street at Narrows Road	Improve crosswalks and pedestrian ramps
	South Main Street at Copicut Street	Improve crosswalks and pedestrian ramps
Fall River Depot Station	North Main Street at President Avenue	Widen North Main Street to provide an exclusive northbound and southbound left-turn lane Modify traffic signal phasing to provide a westbound lead phase and exclusive pedestrian phase
	President Avenue at N. Davol Street	Improve pedestrian timing
Battleship Cove Station	Broadway at Central Street	Improve crosswalks and pedestrian ramps
	Broadway at Anawan Street	Improve crosswalks and pedestrian ramps
Stoughton Station	Brock Street at Washington Street	Install traffic signal

Station	Intersection/Roadway	Mitigation
	Wyman Street at Summer Street/Morton Street	Reconstruct intersection (eliminating driveways, realign Morton St. and install stop sign).

7.4.2 Visual

The Secretary's Certificate on the 2011 DEIR stated that the FEIR should:

- Include clear commitments to specific measures to minimize or mitigate visual impacts associated with the proposed layover facilities.

Section 4.5.5 of this FEIS/FEIR provides an overview of the visual mitigation measures that will be incorporated during preliminary and final design. The proposed visual mitigation measures include siting and designing facilities to minimize changes to the visual landscape, and minimizing vegetation removal along the right-of-way. The proposed Wamsutta layover facility site is in an industrial setting partially occupied by an existing rail yard; the new facility would not appreciably alter the visual environment. The proposed Weaver's Cove East layover facility site is an undeveloped parcel adjoining an abandoned industrial facility and across a primary surface street from a residential neighborhood. It may adversely affect the visual setting of the North Main Street District of Fall River. Mitigation measures such as screening and light minimization would be incorporated during preliminary or final design. The specific mitigation measures proposed for visual impacts are listed in Tables 7.5-1 and 7.5-2.

7.4.3 Noise

The Secretary's Certificate on the 2011 DEIR stated that the FEIR should:

- Include a detailed mitigation plan with commitments at an appropriate level to mitigate for project-related noise impacts.

Section 4.6.3.6 of this FEIS/FEIR provides an overview of the noise mitigation measures that would be incorporated during preliminary and final design. The *Noise and Vibration Mitigation Plan* proposes noise mitigation measures at specific locations. The proposed noise mitigation measures include, for severe noise impacts, installing noise barriers at four locations that meet the MBTA's policy for a noise barrier as a mitigation measure:

- Center Street area from Main Street to Bridge Street in Easton;
- Baldwin Street area from Bridge Street to Parker Terrace in Easton;
- Murray Street area from Brightman Street to Cory Street in Fall River; and
- Almy Street area from Cory Street to President Avenue in Fall River.

For the remaining severely impacted sensitive receptor locations, building insulation is the most cost-effective noise mitigation for reducing the noise impact associated with the rail operations along the Stoughton Electric Alternative. Sound insulation would be provided where appropriate at the remaining sensitive receptor locations that would be impacted by the project. The specific mitigation measures proposed for noise impacts are listed in Tables 7.5-1 and 7.5-2.

7.4.4 Vibration

The Secretary's Certificate on the 2011 DEIR stated that the FEIR should:

- Include a mitigation plan with clear and specific commitments to address vibration impacts and an explanation of the reductions in VdB levels expected.

Section 4.7.5 of this FEIS/FEIR provides an overview of the vibration mitigation measures that will be incorporated during the preliminary and final design process. The *Noise and Vibration Mitigation Plan* proposes vibration mitigation measures at 39 locations along the following streets:

- Stoughton:
  - Brock Street/Washington Street;
  - Rogers Drive/Plain Street; and
  - Smyth Street/Washington Street.
- Easton:
  - Center Street/Williams Street/Avis Circle/Baldwin Street;
  - Laurel Drive;
  - Short Street/Lantern Lane;
  - Kennedy Circle; and
  - Prospect Street.
- Raynham:
  - Bridge Street;
  - Elm Street West;
  - Carver Street;
  - Britton Street; and
  - Wampanoag Road/King Phillip Street/Chickering Road.
- Taunton:
  - Thrasher Street/Malcolm Circle;
  - Summer Street;
  - High Street/Paul Bunker Drive;
  - Hart Street/Alegi Avenue; and
  - Williams Avenue/Plain Street.

- Berkley:
    - Padelford Street;
    - Mill Street; and
    - Adams Lane.
- Freetown:
    - Braley Road;
    - Richmond Road;
    - Forge Road; and
    - High Street/Alexander Drive.
- New Bedford:
    - Lynn Street; and
    - Purchase Street.
- Fall River:
    - Leeward Road;
    - Rolling Green Drive;
    - North Main Street;
    - Pickering Street/Clinton Street/St. James Street;
    - Murry Street/Cory Street/Ballard Street/Almy Street/Railroad Avenue/North Court Street/Brownwell Street/Thompson Street;
    - Dyer Road;
    - Durfee Street/Cedar Street;
    - Maple Street; and
    - Meadow Street.

The proposed vibration mitigation measures include installing ballast mats under the track and using special track construction techniques such as continuously welded rails. The specific mitigation measures proposed for vibration impacts are listed in Table 7.5-1.

7.4.5 Cultural Resources

The Secretary's Certificate on the 2011 DEIR stated that the FEIR should:

- Evaluate mitigation opportunities, including repairs and rehabilitation, for the historic train station in Stoughton;
- Expand on the analysis provided in the DEIR/S with a detailed mitigation plan for impacts to significant historic and archaeological resources; and
- Include commitments to specific mitigation measures for any impacts to cultural resources of importance to Native American Tribes.

The former Stoughton Station building is owned by the MBTA but is not part of the functioning station. The MBTA has declared the building to be surplus and offered it for sale. The Transit Realty Authority issued an Invitation to Bid in 2012, and the sale will include a protective covenant to protect the integrity of the historic building. The sale and re-use of the existing former station building is independent of the South Coast Rail project. The station building cannot be re-used as part of the relocated station, as it is not located adjacent to the proposed station.

As described in Section 4.8.5 of this FEIS/FEIR, MassDOT will develop specific cultural resources mitigation measures during the preliminary and final design process. The mitigation measures will be memorialized in a Programmatic Agreement (PA) to be developed after the FEIS/FEIR is completed, and will be executed by the USACE, MassDOT, the Massachusetts Historical Commission, and potentially other consulting parties. MassDOT will analyze specific construction sites and select mitigation measures during National Historic Preservation Act Section 106 consultation. Detailed site investigations and/or data recovery will be conducted where impacts to archaeological resources are unavoidable.

The mitigation measures that may be implemented to minimize impacts to historic resources include preparing historic archival documentation and providing interpretive signs at archaeological sites, designing stations to be compatible with the character of surrounding historic properties, and using the noise and vibration mitigation measures identified above to minimize impacts to cultural resources. The specific mitigation measures proposed for impacts to cultural resources, which are based on the draft PA, are listed in Tables 7.5-1 and 7.5-2.

7.4.6 Air Quality

The Secretary's Certificate on the 2011 DEIR stated that the FEIR should:

- Include commitments to construction-related mitigation measures;
- Include in the mitigation plan an update on consultation with the Massachusetts Department of Energy Resources, Division of Green Communities in regard to developing a joint approach to promote energy efficiency and greenhouse gas reductions in South Coast Rail communities; and
- Describe in detail the specific commitments that MassDOT will make to contribute towards reductions in vehicle miles travelled and related greenhouse gas emissions through the proposed feeder bus system.

Section 4.9.4 of this FEIS/FEIR provides an overview of the air quality mitigation measures for construction activities that will be incorporated during preliminary and final design. The proposed air quality mitigation measures during construction are listed in Tables 7.5-1 and 7.5-2 and include requirements that contractors adhere to all applicable regulations regarding control of construction vehicle emissions, use after-engine emission controls and ultra-low sulfur diesel fuel, and control dust at construction sites. During operation, the Build Alternatives are expected to reduce air quality impacts as compared to the No-Build Alternative. MassDOT will support the feeder bus system to contribute towards reductions in vehicle miles travelled and related greenhouse gas emissions.

MassDOT has not consulted further with the DOER Division of Green Communities or utility companies at this early planning stage of the project. Selection of an Electric Alternative over a Diesel Alternative would reduce GHG emissions from the project, and the reduction of VMT which would result from the

project under any alternative would further reduce GHGs. No further GHG mitigation measures are proposed.

7.4.7 Biodiversity and Wildlife Habitat

The Secretary's Certificate on the 2011 DEIR stated that the FEIR should:

- Include a detailed evaluation of potential mitigation measures to improve habitat connectivity by methods such as wildlife passage structures through the rail bed and improvements to stream crossings to facilitate passage of fish and wildlife designed so as not to compromise the hydrology of wetlands on either side of the rail bed;
- Propose mitigation measures for unavoidable impacts to wetland hydrology from stream crossing modifications;
- Include an analysis of spans and open bottom arches to meet the Stream Crossing Standards, and consider such arches as mitigation measures throughout the entire rail alignment to the extent they are practicable to improve fish and wildlife passage, and do not interfere with safe train operations;
- Clarify commitments to time-of-year restrictions on construction for specific fish species, or demonstrate that they may not be required if construction is located outside of the area used by diadromous species or uses methods that will not affect fish passage or use spawning riffles;
- Include time-of-year construction restrictions to protect migratory birds;
- Describe commitments to specific enhancements in the Hockomock Swamp and other areas along the rail alignment, as well as commitments to biodiversity protection through land acquisition and conservation;
- Describe proposed measures to avoid and minimize construction and train operational noise impacts during critical wildlife breeding season in spring and early summer; and
- Assess barrier effects to wildlife movement in the Acushnet Cedar Swamp and proposed scheduling and/or other measures to minimize impacts to wildlife movement during project construction and operation.

Section 4.14.3.6 of this FEIS/FEIR provides an overview of the biodiversity mitigation measures that will be incorporated during preliminary and final design. These mitigation measures include replacing bridges and culverts that connect areas of high biodiversity with structures that meet Stream Crossing Standards to facilitate fish and wildlife passage through the rail bed, constructing new wildlife crossings (such as between-rail tunnels) for turtles and amphibians, enhancing or replacing disturbed habitat, and phasing construction with time-of-year restrictions to protect species in sensitive areas during migration or breeding seasons. The specific mitigation measures proposed for impacts to biodiversity and wildlife habitat are listed in Tables 7.5-1 and 7.5-2.

7.4.8 Threatened and Endangered Species

The Secretary's Certificate on the 2011 DEIR stated that the FEIR should:

- Explain in detail how the project will meet the long-term "net benefit" standard in 321 CMR 10.23 regarding impacts to state-listed endangered species, including detailed mitigation plans that should be developed in consultation with the Natural Heritage and Endangered Species Program.

Section 4.15.3.6 of this FEIS/FEIR provides an overview of the endangered species mitigation measures that will be incorporated during preliminary and final design. These mitigation measures include the biodiversity and wildlife habitat mitigation measures described above as well as off-site habitat protection and preservation, and funding research programs to benefit state-listed species. MassDOT has coordinated with the Natural Heritage and Endangered Species Program (NHESP) and the agencies are in agreement on the proposed mitigation measures. The specific mitigation measures proposed for impacts to threatened and endangered species are listed in Table 7.5-1.

7.4.9 Wetlands

The Secretary's Certificate on the 2011 DEIR stated that the FEIR should:

- Propose mitigation measures that will allow the project to be conditioned to contribute to Wetland Protection Act interests. Mitigation measures will be required to off-set the project's direct, indirect, and cumulative impacts. The FEIR should describe specific mitigation measures that will directly mitigate wetland impacts, improve wetland conditions and avoid future indirect and cumulative impacts;

- Include detailed plans for Bordering Land Subject to Flooding mitigation and demonstrate how proposed mitigation will meet Wetlands Protection Act requirements;

- Provide details of mitigation plans for riverfront impacts;

- Describe how lost wetland functions and values will be mitigated;

- Evaluate opportunities to enhance wetlands near the Raynham Dog Track on the west side of the alignment as well as potential "undevelopment" and restoration of portions of the dog track site. The FEIR should identify measures that MassDOT is committed to implement; and

- Identify targeted lands for acquisition by MassDOT as mitigation for the cumulative and indirect impacts to wetlands.

The Secretary's Certificate on the 2011 DEIR also stated that the wetlands mitigation plan should include:

- A 2:1 ratio for Bordering Vegetated Wetlands mitigation (at a minimum), at least 1:1 for all other wetlands. Where the USACE requires higher ratios (e.g., for forested wetlands), the mitigation plan should reflect the federal requirements;

- At least a 2:1 mitigation of rare species impacts subject to consultation with NHESP. In some areas mitigation requirements may be considerably higher—because this is a linear project that results in habitat fragmentation and may have disproportionate impacts on some species;
- An evaluation of potential for restoration/preservation of Atlantic White Cedar (*Chamaecyparis thyoides*) wetlands;
- Meaningful Riverfront Area improvements and/or restoration to mitigate for riverfront impacts;
- On-site elevation-specific compensatory storage for lost flood storage, or if such compensatory storage cannot be provided, demonstrate an insignificant increase in flooding, demonstrate that any incremental increase in flooding could be contained on the Proponent's property, or acquire flood easements; and
- Wetland restoration within the Hockomock ACEC.

Section 4.16.10 of this FEIS/FEIR provides an overview of the wetland mitigation measures that will be incorporated during preliminary and final design. A conceptual mitigation design was prepared for each of the seven proposed wetland establishment and restoration sites. The design took into account the size, elevation, and existing conditions at each site, as well as vegetation cover types surrounding each site. These mitigation designs aim to produce wetland establishment and restoration areas that result in no net loss of wetland functions and values.

Conceptual mitigation measures proposed for impacts to wetlands are listed in Tables 7.5-1 and 7.5-2.

The amount of identified wetland establishment and restoration is greater than the amount required according the regulatory mitigation goals, to allow for changes and reductions to wetland mitigation designs where required based on field conditions. Sites identified as candidates for preservation to meet USACE mitigation requirements in excess of the 2:1 ratio wetland replacement required by MassDEP include a broad range of possible sites to ensure that opportunities for preservation can be developed once exact amounts of preservation acreage needed are known.

Wetland mitigation designs have been advanced to the same level of conceptual design as the track and stations. Final wetland mitigation designs will be developed during the subsequent final design process, after MassDOT has committed funding for project design and construction. It would be premature for MassDOT to acquire property and advance wetland mitigation at this stage of project development. MassDOT could secure options on properties for mitigation for the LEDPA once the regulatory agencies have agreed with the proposed mitigation sites.

7.4.10 Water Quality

The Secretary's Certificate on the 2011 DEIR stated that the FEIR should:

- Clearly identify the Environmentally Sensitive Site Design and Low Impact Development measures to which MassDOT is committed to implement at the proposed stations, parking areas, and layover facilities.

Section 4.17.3.6 of this FEIS/FEIR provides an overview of the water quality and stormwater mitigation measures that will be incorporated during preliminary and final design. These mitigation measures include designing stations with ESSD and LID elements, using stormwater BMPs at stations and layover facilities, improving existing drainage ditches, installing sediment forebays and check dams, and using herbicides in accordance with a Vegetation Management Plan. Drainage from the Hockomock Swamp trestle would be managed in place through the use of infiltration trenches located at intervals beneath the trestle. Construction impacts to stormwater would be managed by a SWPPP. The specific mitigation measures proposed for impacts to water quality are listed in Tables 7.5-1 and 7.5-2.

7.4.11 Hazardous Materials

The Secretary's Certificate on the 2011 DEIR did not include any requirements for mitigation of hazardous materials.

Section 4.12.4 of the FEIS/FEIR provides an overview of the hazardous materials mitigation measures that will be incorporated during preliminary and final design. In accordance with MassDEP requirements, any materials that would be excavated from the project areas would be pre-characterized to determine course of action for removal. The specific mitigation measures proposed for hazardous materials are listed in Table 7.5-2.

7.4.12 Waterways

The Secretary's Certificate on the 2011 DEIR stated that the FEIR should:

- Include measures to compensate for impacts to public access to the shoreline.

Work within Chapter 91 jurisdictional non-tidal rivers and streams waterways will be limited to repairing or replacing existing bridges. The South Coast Rail project is expected to maintain or improve navigability that may exist in these streams by replacing multi-span bridges with single- or double-span structures, resulting in a net benefit to public access.

As discussed in Section 4.18.4, the South Coast Rail project will not result in any adverse impacts to public access along the shoreline within Chapter 91 jurisdiction. No mitigation is required. Work within filled tidelands is limited to repair, replacement or rehabilitating existing track, ballast and culverts within filled tidelands along existing railroad rights-of-way. These improvements within existing active rail corridors will not result in any new impacts to public access to the shoreline. A portion of the Weaver's Cove East would be constructed on filled tidelands. Access to the shoreline at this location is presently restricted by the presence of the active rail corridor. The proposed layover facility will not create any new obstacles to public access to the shoreline.

7.4.13 Public Open Space

The Secretary's Certificate on the 2011 DEIR stated that the FEIR should:

- Include a detailed plan to avoid and minimize impacts and/or to mitigate unavoidable impacts to open space; and
- Quantify all open space impacted by the project and describe mitigation commitments.

Section 4.10.3.6 of the FEIS/FEIR provides an overview of the public open space mitigation measures that will be incorporated during preliminary and final design. Only a small portion of one parcel protected by Article 97 would be required for project construction. The required acquisition is a 0.16-acre portion of the 19.38-acre Stoughton Memorial Conservation Land in Stoughton in order to re-route Morton Street. MassDOT will comply with the Article 97 Land Disposition Policy in identifying and acquiring a suitable replacement property on behalf of the Stoughton Memorial Conservation Land during final design. MassDOT will coordinate with the Town of Stoughton to support acquisition of target open space properties such as those identified in the *Open Space and Recreation Plan* (April 2007) to proportionately offset impacts to the Stoughton Memorial Conservation Land. It is anticipated that any acquisitions negotiated by MassDOT and the Town of Stoughton would be consistent with the *Stoughton Community Preservation Plan, FY2012-2015* (Draft, April 2012). The *Open Space and Recreation Plan* identifies 20 parcels that abut the existing Memorial Lands that are identified as “Areas of Conservation Interest” in the Community Preservation Plan, for their ability to provide a more contiguous holding in the Memorial Land. Land acquisition to comply with the provisions of Article 97 would focus on these parcels. Identifying specific parcels is not appropriate at this stage of the project since funds have not been allocated for design and construction.

7.4.14 Environmental Justice

The Secretary’s Certificate on the 2011 DEIR stated that the FEIR should:

- Include a list of specific mitigation commitments to address noise and vibration impacts to Environmental Justice neighborhoods;
- Clarify if there will be a disproportionate impact to an Environmental Justice community with regard to traditional cultural properties, and if so, what mitigation will be implemented; and
- Specify how financial impacts to Environmental Justice communities will be mitigated.

Section 4.4.3 of the FEIS/FEIR provides an overview of the mitigation measures that will be incorporated during preliminary and final design for impacts to resources within environmental justice neighborhoods. No disproportionate impacts, including financial impacts, would occur and mitigation measures for impacts unique to environmental justice populations are not required. Mitigation measures for unavoidable impacts to environmental justice populations address noise and vibration impacts as discussed in Sections 7.4.3 and 7.4.4, above, and will be incorporated during preliminary and final design.

7.4.15 Land Use

The Secretary’s Certificate on the 2011 DEIR stated that the FEIR should:

- Explain how the Corridor Plan will be implemented in parallel with the proposed rail and station development to ensure appropriate timing of mitigation and to optimize the Smart Growth potential of the project.

Chapter 5 of the FEIS/FEIR provides a description of MassDOT’s intent to support and monitor the smart growth components of the Corridor Plan. Implementation of the Corridor Plan is not the responsibility of

MassDOT. Executive Order 525 requires state agencies to support and implement the policies of the Corridor Plan.[2]

7.5 SUMMARY OF PROJECT MITIGATION MEASURES

The proposed South Coast Rail project will result in impacts to social and natural resources, including transportation, land use, social and economic resources, visual and aesthetic resources, noise, vibration, historical and archaeological resources, protected open space and ACECs, biodiversity, threatened and endangered species, wetlands, water quality, and Chapter 91 Waterways. As documented in Chapter 4, the South Coast Rail project will have beneficial effects on transportation, environmental justice populations, regional mobility, land use, economics, air quality, and climate. Implementation of smart growth measures (such as envisioned by the Corridor Plan), as discussed in Chapter 5 will contribute to long-term benefits in land use, land protection, and economic development and will better allow corridor communities to control future sprawl. The analysis of secondary and cumulative impacts demonstrates that smart growth can contribute to additional benefits with respect to air quality and climate.

7.5.1 Permanent Impacts

Permanent impacts resulting from construction of the South Coast Rail project would be mitigated, as described in Section 7.4 and summarized in Table 7.5-1. The proposed mitigation measures will be refined during the preliminary and final design.

Table 7.5-1 Proposed Project Mitigation Measures for Permanent Impacts

Environmental Categories	Mitigation Measure	Implementation Schedule	Implementation Responsibility
Transportation	Improve crosswalks and pedestrian ramps at locations specified in Table 7.4-1.	During construction	MassDOT/MBTA
	Reconfigure driveways and roads at locations specified in Table 7.4-1.	During construction	MassDOT/MBTA
	Pre-empt crossing signals at locations specified in Table 7.4-1.	During construction	MassDOT/MBTA
	Close intersections at locations specified in Table 7.4-1.	During construction	MassDOT/MBTA
	Improve pedestrian timing at locations specified in Table 7.4-1.	During construction	MassDOT/MBTA
	Construct sidewalks at locations specified in Table 7.4-1.	During construction	MassDOT/MBTA
	Improve signage at locations specified in Table 7.4-1.	During construction	MassDOT/MBTA
	Widen streets to provide exclusive turn lanes at locations specified in Table 7.4-1.	During construction	MassDOT/MBTA
	Re-stripe streets at locations specified in Table 7.4-1.	During construction	MassDOT/MBTA
	Modify traffic signal phasing and timing at locations specified in Table 7.4-1.	During construction	MassDOT/MBTA
	Install traffic signals at locations specified in Table 7.4-1.	During construction	MassDOT/MBTA
	Improve grade crossing safety at locations specified in Table 7.4-1.	During construction	MassDOT/MBTA

[2] Governor Deval L. Patrick. 2010. Executive Order 525: Implementation of the South Coast Rail Corridor Plan. http://www.mass.gov/governor/legislationeexecorder/executiveorder/executive-order-no-525.html.

Environmental Categories	Mitigation Measure	Implementation Schedule	Implementation Responsibility
	Remove gates and signals at existing crossings and replace them with new gates, signals, and signal cases at locations specified in Table 7.4-1.	During construction	MassDOT/MBTA
	Remove vegetation at all grade crossings to improve sight distance.	During construction	MassDOT/MBTA
	Coordinate with local emergency service providers regarding grade crossing design.	During design	MassDOT/MBTA
	Install fencing along right-of-way in developed areas to discourage trespassing.	During construction	MassDOT/MBTA
Visual	Install screening in selected locations.	During construction	MassDOT/MBTA
	Select station lighting fixtures, designs, and technologies that minimize night sky impacts.	During design	MassDOT/MBTA
	Install station lighting that minimizes night-sky impacts.	During construction	MassDOT/MBTA
	Design facilities and structures to blend with the surrounding landscape.	During design	MassDOT/MBTA
Noise	Provide noise walls or other noise measures where sensitive land uses would be subject to Severe impacts (if cost-effective according to MBTA and FTA criteria; e.g., less than $30,000 per dwelling unit) at four locations along the alignment in Easton and Fall River: • Center Street Area, Easton (Main St to Bridge St) • Baldwin Street Area, Easton (Bridge St to Parker Terrace) • Murray Street Area, Fall River (Brightman St to Cory St) • Almay Street Area, Fall River (Cory St to President Ave)	During construction	MassDOT/MBTA
	Provide funding for building noise mitigation where sensitive land uses would experience severe impacts but walls are not cost-effective, at a rate of $5,000 per dwelling unit per decibel of noise impact above the Severe level, up to a maximum of $30,000 for 235 residences: • 21 in Stoughton • 56 in Easton • 23 in Raynham • 23 in Taunton • 14 in Berkley • 8 in Lakeville • 25 in Freetown • 12 in New Bedford • 53 in Fall River	During construction	MassDOT/MBTA
Vibration	Incorporate vibration mitigation measures into the design and operating plan, including continuously welded rail, ballast and sub-ballast depth specifications, turnout locations at least 100 feet away from sensitive receptors, and train and track maintenance (such as regular wheel re-truing) schedules.	During design	MassDOT/MBTA

Environmental Categories	Mitigation Measure	Implementation Schedule	Implementation Responsibility
	Install ballast mats under the tracks at up to 39 locations as specified in Section 4.7 of this FEIS/FEIR where mitigation is justified and soil conditions are appropriate.	During construction	MassDOT/MBTA
Cultural Resources	Where impacts to historic resources are unavoidable, prepare archival documentation and provide interpretive signs that describe for the public the site's history, features, and significance	During construction	MassDOT/MBTA
	Develop and implement a Cultural Resource Monitoring Program	During design and during construction	MassDOT/MBTA
	Develop a mitigation plan, in consultation with the USACE and MHC, to minimize adverse impacts to historic properties as identified in the Programmatic Agreement.	During design	MassDOT/MBTA
	Conduct additional archaeological survey in sensitive areas as identified in the Programmatic Agreement	During design	MassDOT/MBTA
	Evaluate specific construction sites (the Route 138 Grade Separation, proposed Stoughton Station) and conduct detailed site investigations and/or data recovery where impacts to archaeological resources are unavoidable	During design and during construction	MassDOT/MBTA
	In areas where there is a potential for vibration damage to historic structures, inspect building foundations prior to construction and monitor foundations during construction	During design and during construction	MassDOT/MBTA
	Install rubber ballast mats (or equivalent) or moveable point frog turnouts (or equivalent) to minimize potential for vibration-induced damage to historic buildings in Easton	During construction	MassDOT/MBTA
	Design Easton Village Station to be compatible with character of surrounding historic properties such as the adjacent railroad station	During design	MassDOT/MBTA
	Use non-contrasting paints on fences, roadway equipment, and signal bungalows; locate signs and fixtures in a sensitive manner within and adjacent to historic properties	During construction	MassDOT/MBTA
	Within historic districts, reduce visual impacts by reducing clearing and using screening planting and landscaping	During design	MassDOT/MBTA
	Minimize number of lighting poles adjacent to historic properties; paint poles a non-contrasting color	During design	MassDOT/MBTA
Air Quality	Consult with the Massachusetts Department of Energy Resources, Division of Green Communities in regard to developing a joint approach to promote energy efficiency and greenhouse gas reductions in South Coast Rail communities	During design	MassDOT/MBTA
	If diesel alternative is selected, use plug-ins and electric block heaters at rail layover facilities	During design	MassDOT/MBTA
Biodiversity	Where possible when engineering constraints and hydrology are taken into consideration, replace bridges and culverts that connect areas of high biodiversity with structures that meet Massachusetts River and Stream Crossing Standards to facilitate fish and wildlife passage through the rail bed. Table 4.14-36 of the FEIS/FEIR lists the culverts to be reconstructed to meet stream crossing standards.	During construction	MassDOT/MBTA
	Replant disturbed areas.	During construction	MassDOT/MBTA

Environmental Categories	Mitigation Measure	Implementation Schedule	Implementation Responsibility
	Develop and implement an invasive species control plan within the Hockomock Swamp	During construction	MassDOT/MBTA
	Install wildlife crossings (tunnel and between-tie crossings) at the locations specified in Chapter 4.14, *Biodiversity* (Table 4.14-37)	During construction	MassDOT/MBTA
	Consider slope modifications to avoid direct impacts to vernal pools	During design	MassDOT/MBTA
	Work with the Town of Easton and Southeast Regional Vocational School to identify measures to protect vernal pools on their respective properties from ATV damage	During design	MassDOT/MBTA
	Enhance natural vegetation within buffer zones to vernal pools, where appropriate.	During design	MassDOT/MBTA
	Adhere to the approved Vegetation Management Plan (see Water Quality section of this table).	During operation	MassDOT/MBTA
Threatened and Endangered Species	Install wildlife crossings (tunnel and between-tie crossings) to maintain population continuity for state-listed wildlife, at the locations specified in Chapter 4.14, *Biodiversity*.	During construction	MassDOT/MBTA
	Provide funding or land acquisition to protect up to 25 acres of land potentially used by the Hockomock Swamp population of Blanding's turtle.	During construction	MassDOT/MBTA
	If required by NHESP in the Conservation and Management Permit, fund a study of the Hockomock Swamp population of Blanding's turtle to assist NHESP in developing long-term protective measures.	During construction	MassDOT/MBTA
	Provide funding or land acquisition to protect up to 11 acres of land potentially used by the Hockomock Swamp population of blue-spotted salamander.	During construction	MassDOT/MBTA
	Provide funding to the NHESP eastern box turtle Mitigation Bank equivalent to protecting up to 17 acres of habitat, or directly protect up to 17 acres of habitat through land acquisition or restriction.	During construction	MassDOT/MBTA
Wetlands	Create/restore up to 33.7 acres of wetlands and waterways at up to seven sites, at ratios determined in consultation with MassDEP, USACE, depending on cover type, for no net loss of wetland functions and values. See Table 4.16-62 of the FEIS/FEIR.	During design and during construction	MassDOT/MBTA
	Create/restore up to 6.7 acres of BLSF to provide compensatory flood storage, as required by the WPA Variance. See Table 4.16-61 of the FEIS/FEIR.	During design and construction	MassDOT/MBTA
	Monitor compensatory wetlands for success and invasive plant species, and implement an Invasive Species Control Plan during a post-construction monitoring period as required by the Section 404 permit.	5-10 year post construction monitoring period	MassDOT/MBTA

Environmental Categories	Mitigation Measure	Implementation Schedule	Implementation Responsibility
	Select and preserve wetlands and adjacent developable uplands at Priority Preservation Area sites if the area of federal wetland mitigation needed would not be fully achieved by wetland establishment, enhancement, or restoration.	During design and construction	MassDOT/MBTA
Water Quality	Improve railroad drainage system to promote settling and infiltration.	During construction	MassDOT/MBTA
	Install sediment forebays and check dams upgradient of discharge points.	During construction	MassDOT/MBTA
	Line drainage ditches within drinking water protection areas.	During construction	MassDOT/MBTA
	Design traction power substations with secondary containment structures.	During construction	MassDOT/MBTA
	Install retention ponds, rain gardens, and other treatment/control features at station sites.	During construction	MassDOT/MBTA
	Design and install stormwater management systems at layover facilities to meet stormwater management standards for LUHPPLs.	During design and during construction	MassDOT/MBTA
	Adhere to the approved Vegetation Management Plan, as implemented with MassDOT's Yearly Operating Plans, which restrict the use of herbicides in areas adjacent to wetlands or sensitive resources.	During operation	MassDOT/MBTA
Article 97	Identify and acquire replacement open space to compensate for the loss of 0.16 acre of public open space in Stoughton.	Prior to construction	MassDOT/MBTA
Land Use	Implement the Smart Growth measures of the Corridor Plan as applicable in accordance with Executive Order 525.	Prior to, during, and after construction	State agencies listed in EO 525
	Provide incentives and guidance to municipalities for Smart Growth implementation.	Prior to, during, and after construction	State agencies listed in EO 525
	Monitor Smart Growth implementation using approved performance metrics.	Prior to, during, and after construction	EOHED

7.5.2 Construction Impacts

Temporary, short-term impacts from construction activities would be mitigated to the extent practicable as summarized in Table 7.5-2. Appropriate construction mitigation measures would be incorporated into the contract documents and specifications governing the activities of contractors and subcontractors constructing elements of the proposed project. Specific mitigation measures for construction impacts would be developed during the final design phase of the South Coast Rail project and would be reviewed by the appropriate regulatory agencies as part of the permit applications. Construction-period mitigation requirements would be incorporated into the final plans and specifications that would serve as the basis for the construction contract(s).

Table 7.5-2 Proposed Project Mitigation Measures for Construction-period Impacts

Environmental Categories	Mitigation Measure	Implementation Schedule	Implementation Responsibility
Visual	Avoid unnecessary tree clearing along rights-of-way	During construction	MassDOT/MBTA
Noise	Maintain mufflers on construction equipment.	During construction	MassDOT/MBTA
	Keep truck idling to a minimum in accordance with MassDEP anti-idling regulations.	During construction	MassDOT/MBTA
	Fit any air-powered construction equipment with pneumatic exhaust silencers.	During construction	MassDOT/MBTA
	Prohibit nighttime construction.	During construction	MassDOT/MBTA
	Institute time-of-year construction restrictions during breeding seasons in sensitive habitat areas including the Hockomock Swamp, Pine Swamp, and Acushnet Cedar Swamp.	During construction	MassDOT/MBTA
Cultural Resources	In areas where there is a potential for vibration damage to structures, inspect building foundations prior to construction and monitor foundations during construction.	During design and during construction	MassDOT/MBTA
Air Quality	Prohibit excessive idling of construction equipment and trucks in accordance with MassDEP anti-idling regulations.	During construction	MassDOT/MBTA
	Require that all diesel equipment used on-site will be fitted with after-engine emission controls, including diesel oxidation catalysts and/or particulate filters. This would include on-road vehicles on which catalysts or filters can be accommodated.	During construction	MassDOT/MBTA
	Require use of ultra-low sulfur diesel fuel for all construction vehicles.	During construction	MassDOT/MBTA
	Provide dust protection at work sites.	During construction	MassDOT/MBTA
Biodiversity	Avoid tree clearing within the right-of-way in the Hockomock Swamp, Pine Swamp, Assonet Cedar Swamp and Acushnet Cedar Swamp from May 1 to July 15.	During construction	MassDOT/MBTA
	Observe time-of-year restrictions for in-water bridge work as identified in Table 4.14-33 of the FEIS/FEIR (generally from March 15 to June 30). Coordinate with DMF to identify restrictions that protect fish spawning in the Taunton River while allowing bridge construction.		
Threatened and Endangered Species	Install staked, entrenched siltation fencing at all limits of work within rare species habitat areas.		
	Install one-way turtle gates within areas of mapped habitat of listed turtle species (Blanding's, eastern box).		
	Daily monitoring of the work area within areas of mapped habitat of listed turtle species from spring through fall, as required by the Conservation and Management permit. Any animals found within the work area would be relocated.		
	Restrict construction in the Hockomock Swamp to daylight hours during amphibian breeding season (March-April).		
Wetlands	Implement erosion and sedimentation control measures according to a Soil Erosion and Sediment Control Plan.	During construction	MassDOT/MBTA

Environmental Categories	Mitigation Measure	Implementation Schedule	Implementation Responsibility
Water Quality	Develop and implement a comprehensive Soil Erosion and Sediment Control Plan in accordance with NPDES and MassDEP standards.	During construction	MassDOT/MBTA
	Apply water to dry soil to prevent dust production.	During construction	MassDOT/MBTA
	Stabilize any highly erosive soils with erosion control blankets and other stabilization methods, as necessary.	During construction	MassDOT/MBTA
	Use sediment control methods (such as silt fences and hay bales), during excavation to prevent silt and sediment entering the stormwater system and waterways.	During construction	MassDOT/MBTA
	Maintain equipment to prevent oil and fuel leaks.	During construction	MassDOT/MBTA
	Design a construction-phase SWPPP that incorporates the following: Erosion and sediment controls Spill control procedures Proper handling of dewatering discharges	During construction	MassDOT/MBTA
Hazardous Materials and Solid Waste	Prepare Hazardous Materials and Solid Waste Management Plan, and Health and Safety Plan, to describe the regulatory context and procedures to be used during construction.	During design	MassDOT/MBTA
	Pre-characterize any materials that would be managed during the project to determine the course of action for excavation and disposal.	During construction	MassDOT/MBTA
	Pre-characterize construction materials in buildings that would be demolished to identify special or hazardous waste and determine the course of action for removal and disposal.	During construction	MassDOT/MBTA

8 REGULATORY COMPLIANCE

8.1 INTRODUCTION

In addition to complying with the NEPA and the MEPA, a number of state and federal permits are needed for the proposed South Coast Rail project. Table 8.1-1 lists the required state and federal permits, determinations, and approvals. All listed agencies also participate in the environmental review of the project through the NEPA and/or MEPA processes. In addition to being presented in a consolidated manner in this chapter they are also discussed in the resource chapters. This chapter focuses on the regulatory compliance of the Stoughton Electric Alternative as the Preferred and LEDPA.

Table 8.1-1 Required Permits and Approvals

Issuing Agency	Approval or Permit
U.S. Army Corps of Engineers	Clean Water Act, Section 404 Individual Permit
	Section 10 of the Rivers and Harbors Appropriation Act of 1899
U.S. Environmental Protection Agency	Clean Water Act, Section 402 National Pollutant Discharge Elimination System, General Permit for Construction Activities & Multi-Sector General Permit for Industrial Activities
U.S. Coast Guard	Section 9 of the Rivers and Harbors Appropriation Act of 1899 and the General Bridge Act of 1946
Massachusetts Office of Coastal Zone Management	Coastal Zone Management Act, Federal Consistency Certification
Massachusetts Executive Office of Energy and Environmental Affairs	Public Benefits Determination
Massachusetts Department of Environmental Protection	Massachusetts Wetlands Protection Act Variance
	Massachusetts Public Waterfront Act (Chapter 91) License(s)
	Clean Water Act, Section 401 Water Quality Certificate Variance
Massachusetts Department of Fish and Game	Massachusetts Endangered Species Act Conservation and Management Permit

The Secretary's Certificate on the DEIR included the following regulatory compliance requirements:

- The project will require several variances from Wetlands regulations performance standards. One of the three criteria for a variance is a demonstration that the variance is necessary to accommodate an overriding public interest. The FEIR should further refine how the proposed Stoughton Electric rail will advance the public interests identified in the DEIR/DEIS.

- To demonstrate eligibility for a variance MassDOT must also propose mitigation measures that will allow the project to be conditioned to Wetland Protection Act interests.

- The FEIR should include a comprehensive description of how MassDOT proposes to meet MESA regulatory requirements, including the standards for authorizing a take of a state-listed species through a Conservation and Management Plan.

- The FEIR should expand upon the evaluation in the DEIR/DEIS to demonstrate consistency with EEA Article 97 Land Disposition Policy.

- The FEIR should identify permits required for layover facilities and document how the proposed facilities will comply with applicable regulatory requirements. Consistency with Chapter 91 licensing requirements and requirements for location within a Designated Port Area (DPA) should be described as applicable.

- The FEIR should describe how the project will comply with the Massachusetts Stormwater Standards for work proposed in wetland resource areas and buffer zones pursuant to 310 CMR 10.05(6)(k) and 314 CMR 9.06(6), as well as other state and federal requirements (including Total Maximum Daily Load [TMDL] requirements) for stormwater discharges to existing outfalls and/or for the proposed layover facilities.

- The FEIR should include an assessment of the ability of the proposed project to meet the ten Massachusetts Stormwater Standards or specify if a variance to the standards specified at 310 CMR 10.05(6)(k) and 314 CMR 9.06(6) may be required.

- The FEIR should describe in detail how the project will meet licensing standards at 310 CMR 9.54 and 9.55 (for non-water-dependent) and 301 CMR 9.31-9.40 (for water dependent).

The following sections describe the required permits and approvals for the South Coast Rail project, and how the project complies with each.

8.2 CLEAN WATER ACT SECTION 404

This section describes the regulatory context, regulatory requirements, and how the South Coast Rail project would comply with the federal Clean Water Act[1] Section 404 permit program.

8.2.1 Regulatory Context

Section 404 of the Clean Water Act regulates the discharge of dredged or fill material into "Waters of the United States," including adjacent wetlands. The South Coast Rail project would require the issuance of a Section 404 Individual Permit (i.e., would not be eligible for the Massachusetts Programmatic General Permit) as it would result in the loss of more than 1 acre of waters of the United States.

On May 8, 2008, MassDOT submitted an application to the USACE for Individual Permit authorization under the Section 404 program.

8.2.2 Regulatory Requirements

Fill activities are evaluated using the USEPA's Guidelines for Specification of Disposal Sites for Dredged or Fill Material promulgated pursuant to Section 404(b)(1) of the Clean Water Act[2] (Section 404(b)(1) Guidelines). The Section 404(b)(1) Guidelines are designed to avoid unnecessary filling of special aquatic sites, which are defined as:

[1] Formally, the Federal Water Pollution Control Act.
[2] 40 CFR 230 *et seq*.

"Geographic areas, large or small, possessing special ecological characteristics of productivity, habitat, wildlife protection, or other important and easily disrupted ecological values. These areas are generally recognized as significantly influencing or positively contributing to the general overall environmental health or vitality of the entire ecosystem of a region."[3]

Wetlands and riffle and pool complexes are both categories of special aquatic sites. The Guidelines state that "all practicable alternatives to the proposed discharge [of dredged or fill material], which do not involve a discharge into a special aquatic site, are presumed to have less adverse impact on the aquatic ecosystem, unless clearly demonstrated otherwise." As described in 40 CFR 230.10 (with some exceptions),

- No discharge of dredged or fill material shall be permitted if there is a practicable alternative to the proposed discharge which would have less adverse impact on the aquatic ecosystem, so long as the alternative does not have other significant adverse environmental consequences;
- No discharge of dredged or fill material shall be permitted if it:
  - Causes or contributes to violations of any applicable State water quality standard;
  - Violates any applicable toxic effluent standard or prohibition;
  - Jeopardizes the continued existence of species listed as endangered or threatened or results in the destruction or adverse modification of designated critical habitat; or
  - Violates any requirement to protect any designated marine sanctuary;
- No discharge of dredged or fill material shall be permitted which will cause or contribute to significant degradation of the waters of the United States; and
- No discharge of dredged or fill material shall be permitted unless appropriate and practicable steps have been taken which will minimize potential adverse impacts of the discharge on the aquatic ecosystem.

8.2.3 Regulatory Compliance

This section describes how the South Coast Rail project would comply with the four Section 404(b)(1) Guidelines listed above.

8.2.3.1 Practicable Alternatives

Practicable means available and capable of being done after taking into consideration cost, existing technology, and logistics in light of the overall project purpose. The practicability of the alternatives is considered by the USACE in determining whether there is a less environmentally damaging practicable alternative to that which is proposed.

The overall project purpose is used by the USACE to evaluate whether there are less environmentally damaging practicable alternatives available. The overall project purpose for the South Coast Rail project

[3] 40 CFR 230.3(q-1)

is defined by the USACE as: “to more fully meet the existing and future demand for public transportation between Fall River/New Bedford and Boston, MA, and to enhance regional mobility.” This definition is specific enough to define MassDOT’s needs, but not so restrictive as to constrain the range of alternatives that must be considered under the Section 404(b)(1) Guidelines.

Chapter 3, *Alternatives*, describes the range of alternatives considered for the South Coast Rail project and identifies the Stoughton Electric Alternative as the recommended LEDPA. There are no less environmentally damaging practicable alternatives that meet the overall project purpose. The evaluation of the environmental impacts of the alternatives is provided in Chapter 4, *Affected Environment and Environmental Consequences*, and Chapter 5, *Indirect Effects and Cumulative Impacts*.

8.2.3.2 Water Quality

The South Coast Rail project has been designed by MassDOT to comply with Massachusetts Stormwater Standards. The project includes proposed stormwater management systems to minimize impacts to water quality by controlling runoff velocities and removing pollutants from the stormwater runoff discharging from the railroad bed, layover facilities, and station locations to downstream surface water resources. Due to the potential impacts to Outstanding Resource Waters (ORWs), the project would require a variance from the state water quality standards (Clean Water Act Section 401), as described in Section 8.8 of this chapter.

8.2.3.3 Threatened and Endangered Species

Section 7 of the Endangered Species Act requires Federal agencies to consult with the Secretary (of the Interior or Commerce Departments; generally as represented by the Fish and Wildlife Service and the National Marine Fisheries Service [NMFS], respectively) on any action that is likely to jeopardize the continued existence of a species listed or proposed for listing on federal threatened and endangered species lists. The South Coast Rail project would not affect any federally listed endangered species, because there are none within the action area. Since the publication of the DEIS, Atlantic sturgeon (*Acipenser oxyrinchus*; NY Bight population) has been listed as federally endangered. The Taunton River “mouth” is specifically named in the Federal Register listing (FR77-5912, Feb 6, 2012). Although the Taunton River crossings are upstream of the river mouth, the Corps contacted the NMFS to inquire about the possible effects of South Coast Rail on this species. NMFS has determined that “no species listed under [their] jurisdiction are likely to be exposed to any direct or indirect effects of the proposed project.” Therefore, no further Section 7 consultation is required.

8.2.3.4 Waters and Wetlands

The Section 404(b)(1) Guidelines stipulate that “no discharge of dredged or fill material shall be permitted which will cause or contribute to significant degradation of the waters of the United States.” Measures to protect and avoid impacts to wetlands and water resources were incorporated into the conceptual design. Construction practices (such as use of BMPS) would be implemented in accordance with state and federal guidelines to prevent unnecessary impacts to wetland and water resources. Unavoidable impacts would be mitigated.

Avoidance was considered along the South Coast Rail project corridor when designing track layout at the current conceptual level. Tracks were kept within the existing railbed footprint where possible. Complete avoidance is only possible through the No-Build Alternative, which does not achieve the project purpose and need. Minimization was achieved through structures such as retaining walls to reduce grading of slopes where the existing railroad embankment was widened. Single track design was

used wherever possible to minimize widening of the right-of-way. Special construction techniques, such as retaining walls to minimize the lateral extent of the project footprint and the Hockomock Trestle to pass over the Hockomock Swamp, have been incorporated into the design of the Stoughton Alternative to minimize adverse impacts to wetlands.

For the Stoughton Electric Alternative, a total of just over 1 acre of palustrine emergent wetlands would be permanently impacted, requiring 2.1 acres of mitigation. A total of 0.9 acre of palustrine scrub-shrub wetlands would be permanently impacted, requiring 1.8 acres of mitigation. A total of 8.5 acres of palustrine forested wetlands would be permanently impacted, requiring 25.5 acres of mitigation. A total of 1.9 acres of open water would be permanently impacted, requiring 1.9 acres of mitigation. An additional 2.4 acres of temporary impacts to palustrine forested wetlands would require mitigation. Mitigation would seek to replace the functions and values lost due to wetland impacts. During final design, a comprehensive assessment of functions and values would be performed onsite including wildlife habitat assessments, in order to refine the information on functions and values provided by wetlands along the project corridor.

8.3 CLEAN WATER ACT SECTION 402

This section describes the regulatory context, regulatory requirements, and how the South Coast Rail project would comply with the Clean Water Act Section 402 requirements.

8.3.1 Regulatory Context

Section 402 of the Clean Water Act regulates the discharge of pollutants to surface waters. Under the National Pollutant Discharge Elimination System (NPDES) program that is authorized by Section 402, owners and operators of point source discharges and certain non-point discharges (such as stormwater runoff) are required to obtain a permit prior to discharging. The NPDES program includes both General and Individual Permits. The General Permit for Construction Activities regulates erosion control, pollution prevention, and stormwater management at construction sites over 1 acre. A Multi-Sector General Permit for Industrial Activities is appropriate for operations at sites such as the proposed South Coast Rail layover facilities, and regulates discharges of site-specific pollutants. An Individual Section 402 Permit is not required for the South Coast Rail project.

8.3.2 Regulatory Requirements

Two types of permits would be required to construct and operate the South Coast Rail project. The NPDES General Permit for Construction Activities requires construction contractors to prepare a Stormwater Pollution Prevention Plan (SWPPP) that describes the BMPs that will be implemented to minimize or eliminate discharges of pollutants from construction sites. A NPDES Multi-Sector General Permit for Industrial Activities would establish site-specific conditions that must be met by the site operator, and also include SWPPP requirements.

8.3.3 Regulatory Compliance

This section describes how the South Coast Rail project would comply with the NPDES General Permit for Construction Activities requirements and the Multi-Sector General Permit for Industrial Activities to address stormwater dischargers from each of the proposed layover facilities.

MassDOT would prepare a Notice of Intent (NOI) to request authorization for coverage of the South Coast Rail project under the NPDES General Permit for Construction Activities. A SWPPP would be developed by the construction contractor that specifies proper stormwater management procedures for any disturbed areas. Construction period impacts to water quality would be reduced or eliminated through the use of appropriate BMPs that would be documented in the SWPPP. The BMPs would include perimeter sedimentation controls (silt fence, hay bales, filter berms, siltation booms), temporary stabilization of disturbed areas, and temporary siltation basins where appropriate. The SWPPP would be completed during the final design phase and is required to be implemented by the project contractor.

MassDOT would also prepare a NOI to request authorization for coverage under the Multi-Sector General Permit for Industrial Activities for each of the proposed layover facilities. Both of the layover facilities have been conceptually designed to meet Massachusetts Stormwater Standards, and further refinement would be made during preliminary and final design. A site-specific SWPPP would be completed for each facility that provides an assessment of potential sources of pollutants in stormwater runoff and control measures that will be implemented at the layover facility to minimize the discharge of these pollutants in runoff from the site. These control measures include site-specific BMPs, maintenance plans, inspections, employee training, and reporting.

8.4 SECTION 10 OF THE RIVERS AND HARBORS ACT OF 1899

Section 10 of Rivers and Harbors Appropriation Act of 1899, (33 U.S.C. 403) requires a Department of the Army permit for structures and/or work in or affecting navigable waters of the United States. In the case of South Coast Rail, the Taunton River is a tidal navigable water of the United States up to the South Street East Bridge in Taunton, and the Mill River in Taunton is navigable to Spring Street in Taunton. Should the South Coast Rail proposal involve any placement of structures or work (except bridges) in or affecting the Taunton or Mill Rivers, it will be necessary for MassDOT to obtain Department of the Army authorization under Section 10, in addition to the authorization to discharge dredged or fill material under Section 404 of the Clean Water Act. On May 8, 2008, MassDOT applied for a Department of the Army permit and that application is accepted pursuant to Corps' authority under both Section 10 and 404.

The Corps does not have authority over bridges under the Rivers and Harbors Act of 1899, as that authority has been delegated to the U.S. Coast Guard (see below). Corps authority over bridges is limited to appurtenant structures such as abutments and bank stabilization, the construction of which may involve discharges of dredged or fill material, and as such are regulated under Section 404 of the Clean Water Act.

8.5 COASTAL ZONE MANAGEMENT ACT

This section describes the regulatory context, regulatory requirements, and how the South Coast Rail project would comply with federal Coastal Zone Management Act requirements and the Massachusetts Coastal Zone Management Standards and Policies.

8.5.1 Regulatory Context

Section 307(c) of the Coastal Zone Management Act of 1972, as amended (16 U.S.C. 1456(c)) requires federal agencies conducting activities, including development projects, directly affecting a state's coastal zone, to comply to the maximum extent practicable with an approved state coastal zone management

program. The Act also requires any non-federal applicant for a federal license or permit to conduct an activity affecting land or water uses in the state's coastal zone to furnish a certification that the proposed activity will comply with the state's coastal zone management program. Generally, no permit will be issued until the state has concurred with the non-federal applicant's certification.

The Massachusetts Coastal Zone Management Plan (CZMP) and regulations implement the federal Coastal Zone Management Act. The Coastal Zone Management Act established federal statutory authority to manage the nation's coastal resources in order to balance economic development with environmental conservation. The Massachusetts Coastal Zone Management Act established local authority to implement the Massachusetts CZMP.

8.5.2 Regulatory Requirements

The following CZM regulations are applicable to the South Coast Rail project:

- 301 CMR 21.00 requires a federal consistency certification issued by the Office of Coastal Zone Management for projects in the coastal zone deemed likely to affect the coastal zone and that require a federal action.
- 301 CMR 23.00 establishes state procedures for the preparation of Municipal Harbor Plans. Approved plans provide municipalities a mechanism for modifying certain requirements of Chapter 91 Licensing.
- 301 CMR 25.00 establishes state authority to delineate DPAs within the coastal zone to protect the unique capacity of developed ports and port infrastructure to support water-dependent industrial activities.

These regulations, in concert with the Waterways Regulations (310 CMR 9.00), create a regulatory framework for planning, licensing and implementing projects in the Massachusetts Coastal Zone. The South Coast Rail project includes track, stations and layover facilities within the Massachusetts Coastal Zone and would require compliance with these regulations.

8.5.3 Regulatory Compliance

The following subsections describe how South Coast Rail project elements within the Massachusetts Coastal Zone and DPAs comply with applicable water quality policies, and the DPA regulations.

8.5.3.1 Compliance with Water Quality Policies

Compliance with state water quality policies is a requirement for federal consistency under the CZMP and 301 CMR 21.98. This regulation establishes the CZMP’s programmatic policies and management principles which form the basis for federal consistency. Three water quality policies are applicable to the South Coast Rail project.

Water Quality Policy #1

Ensure that point-source discharges in or affecting the coastal zone are consistent with federally approved state effluent limitations and water quality standards.

Table 8.5-1 lists the applicable state and federal water quality regulations regarding point-source, nonpoint-source, and subsurface discharges at proposed stations and layover facilities. The South Coast Rail project has been designed to meet these environmental protection requirements through compliance with all applicable federal and state regulations governing sources of air and water pollution and wetland protection.

Water Quality Policy #2

Ensure that nonpoint pollution controls promote the attainment of state surface water quality standards in the coastal zone.

Compliance with the NPDES General Permit for Construction Activities would be achieved as described in Section 8.3.3; compliance with the Wetlands Protection Act stormwater regulations is described in Section 8.7.

Table 8.5-1 Water Quality Regulations

Law or Regulation	Program	Applicable?	Compliance
310 CMR 10.05(k)	Massachusetts Wetlands Protection Act: Stormwater Regulations	Applicable to all track, stations and layover facilities within 100 feet of state-regulated wetlands.	MassDOT would seek a Variance under the Wetlands Protection Act for wetland alteration but will comply with all applicable stormwater regulations. See Section 8.7.
314 CMR 3.00	Surface Water Discharge Permit Program	No	The project does not include any discharges to waters of the Commonwealth.
314 CMR 4.00	Surface Water Quality Standards	No	No discharges to surface water are proposed.
314 CMR 5.00	Groundwater Discharge Program	No	No discharges of pollutants to groundwater are proposed.
314 CMR 9.00	Clean Water Act Section 401 Water Quality Certification	The South Coast Rail project will require an Individual Water Quality Certificate.	The project would be designed and constructed in compliance with the Water Quality Certificate. See Section 8.8.
33 USC 1342 (Clean Water Act)	NPDES General Permit for Construction Activities	Yes	MassDOT would submit an NOI requesting authorization for stormwater discharges under the General Permit for Construction Activities. See Section 8.3.
	NPDES Multi-Sector General Permit for Industrial Activities	Yes	MassDOT would submit and NOI requesting authorization for stormwater discharges under the Multi-Sector General Permit for operations at the proposed layover facilities. See Section 8.3.
	NPDES Remediation General Permit (RGP)	TBD	An application for coverage under the RGP would be submitted as needed to authorize the collection, treatment and discharge for groundwater from applicable sites containing oil and hazardous materials.

Water Quality Policy #3

Ensure that activities in or affecting the coastal zone conform to applicable state requirements governing sub-surface waste discharges and sources of air and water pollution and protection of wetlands.

A summary of compliance with each of these conditions is provided below.

Subsurface Waste Discharges

The South Coast Rail project does not include any subsurface waste discharges.

Air Pollution

The South Coast Rail project would result in a net reduction in air pollution and a net benefit to regional air quality as described in detail in Chapter 4.9, *Air Quality.* The Stoughton Electric Alternative would not result in any direct project emissions from the locomotives, layover facilities, or stations. Motive power and electric service to proposed stations and layover facilities would be supplied by existing electric generating facilities with adequate capacity to serve the project without requiring expansion.

The South Coast Rail project would comply with the Clean Air Act Amendments (CAAA) and the Executive Office of EEA policy on greenhouse gas emissions, and is not anticipated to require any new local, state, or federal permit related to air pollution.

Water Pollution

The South Coast Rail project would meet all applicable local, state, and federal requirements regarding potential water pollution, and MassDOT would obtain all needed permits under these regulations as described in Table 8.5-1. No point source discharges are proposed. All stormwater collected at stations and layover facilities would be treated in accordance with the Massachusetts Stormwater Regulations and in accordance with applicable NPDES discharge requirements.

Wetland Protection

The South Coast Rail project would protect state and federally regulated wetlands by adherence to all applicable regulations. The project has been designed to avoid, minimize, and mitigate wetland impacts to the greatest extent practicable and are subject to permit requirements under Section 404 of the federal Clean Water Act, the Massachusetts Wetlands Protection Act, and Section 401 of the Clean Water Act (Water Quality Certificate), as described in Sections 8.2, 8.7, and 8.8, respectively.

8.5.3.2 Compliance with Designated Port Area Regulations

Massachusetts regulations at 301 CMR 25.00 establish state authority to delineate DPAs within developed industrial waterfronts. The purpose of delineating DPAs is to identify geographic areas of particular state, regional and national significance with respect to the promotion of commercial fishing, shipping and other vessel-related activities associated with water-bourne commerce, and of manufacturing, processing, and production activites.

The South Coast Rail project includes track work in the the Mount Hope Bay (Fall River) and New Bedford/Fairhaven DPAs. The only South Coast Rail project elements within these DPAs are the following existing track segments:

- Mount Hope Bay
  - Reconstruct 2,000 + LF of track south of the proposed Weaver's Cove East Layover Facility

- Reconstruct 500 + LF of track north of the proposed Battleship Cove Station

- New Bedford/Fairhaven

  - Reconstruct 500 + LF of track south of the proposed Wamsutta Layover Facility

The project-related work proposed within these DPAs is the reconstruction of existing track, ballast, and associated infrastructure. The South Coast Rail project has been designed to avoid construction of stations and layover facilities within the DPAs.

The CZM regulations include port and harbor infrastructure policies and management principles for projects located in the Massachusetts Coastal Zone. Two policies and management principles are applicable to the South Coast Rail project.

Ports Policy #3

Preserve and enhance the capacity of DPAs to accommodate water-dependent industrial uses, and prevent the exclusion of such uses from tidelands and any other DPA lands over which a state agency exerts control by virtue of ownership, regulatory authority or other legal jurisdiction.

Reconstructing the existing track, ballast and related infrastructure would result in a direct benefit to the DPAs' capacity to support water-dependent industrial uses by improving the railroad transportation infrastructure serving these ports. The South Coast Rail project would improve the freight transportation capacity on the New Bedford Main Line from Taunton to the Port of New Bedford and on the Fall River Secondary to Fall River. These improvements would improve the capacity of the DPAs to support water-dependent industrial uses without developing land within the DPAs for non-water dependent uses.

Ports Management Principle #1

Encourage, through technical and financial assistance, expansion of water dependent uses in designated ports and developed harbors, re-development of urban waterfronts, and expansion of visual access.

The proposed improvements within the Mount Hope Bay (Fall River) and New Bedford/Fairhaven DPAs will provide substantial financial assistance to these ports by replacing and upgrading existing rail infrastruture. These upgrades will substantially improve the load capacity of the existing tracks serving these ports, increasing the capacity for the DPAs to serve as as sea/land intermodal freight node and improve their potential to serve water-dependent industrial uses. The South Coast Rail project has been designed to avoid the construction of any non-water dependent use facilities within the DPAs while substantially improving transportation infrastructure.

The proposed track reconstruction will not adversely affect public views of the shoreline because the work is limited to the reconstruction of existing at-grade railroad infrastructure. No new stations or layover facilities are proposed in any DPA.

8.6 MASSACHUSETTS PUBLIC BENEFITS DETERMINATION

This section describes the regulatory context, regulatory requirements, and how the South Coast Rail project would comply with requirements to obtain a Public Benefit Determination.

8.6.1 Regulatory Context

Portions of the South Coast Rail project are subject to the requirements of Chapter 168 of the Acts of 2007[4] because they are located on landlocked filled tidelands. The South Coast Rail project exceeds review thresholds as defined in 301 CMR 11.03 and would require a Public Benefit Determination by the Secretary of the Executive Office of EEA in accordance with the regulations at 301 CMR 13.00. Projects subject to MEPA are required to consider potential impacts on groundwater and, in cases where projects are located in areas of known low groundwater, include measures to avoid, minimize, or mitigate potential impacts.

8.6.2 Regulatory Requirements

When making a Public Benefit Determination, the Secretary is required to consider the:

- Purpose and effect of the development;
- Impact on abutters and the surrounding community;
- Enhancement of the property;
- Benefits to the public trust rights in tidelands or other associated rights;
- Community activities on the development site;
- Environmental protection and preservation;
- Public health and safety, and
- General welfare.

The Secretary is also instructed by 301 CMR 13.00 to consider the differences between tidelands, landlocked tidelands and great ponds when assessing the public benefit and shall consider the practical impact of the public benefit on development.

8.6.3 Regulatory Compliance

The South Coast Rail project elements proposed within landlocked tidelands have been sited and preliminarily designed to protect the public interests in tidelands and result in public benefits. The project would result in substantial net benefits to the public interest in filled tidelands by revitalizing and expanding public infrastructure in a manner which meets all applicable state and federal environmental protection standards while minimizing potential impacts to abutters to these sites and the community.

The project elements that are located on filled tidelands, located at least 250 feet landward of existing flowed tidelands, and are completely separated from flowed tidelands by one or more intervening roads are:

- Battleship Cove Station,
- Whale's Tooth Station, and

[4] An Act Relative to Licensing Requirements for Certain Tidelands: Section 8, Chapter 168 of the Acts of 2007.

- Wamsutta Layover Facility.

The following sections describe how these project elements would provide public benefits and are adequately protective of the public's inherent rights in present and former waterways, held in trust by the Commonwealth for the benefit of the public.

8.6.3.1 Battleship Cove Station

The Battleship Cove Station would be a new station constructed at the southern terminus of the Fall River Secondary, on Water Street in Fall River. The station would be a platform-only station that would operate during peak hours. It would serve downtown Fall River and the Battleship Cove tourist area. The site is approximately 825 feet from the nearest flowed tidelands of the Taunton River. A portion of the site is located on filled tidelands entirely separated from the flowed tidelands by Water Street. The public benefits of the proposed Battleship Cove Station are described below.

Purpose and Effect of the Development

The purpose of the Battleship Cove Station is to provide new passenger rail access to the Fall River downtown and tourist waterfront area, improving access to the MBTA and regional public transportation network. The station would be accessible to passengers walking, biking, or driving to the station.

The effects of the development would be:

- Creation of a new public transportation facility providing regional commuter rail service to downtown Fall River and the Battleship Cove area where none presently exists; and
- Construction within approximately 10,000 square feet of filled tidelands for the platform.

Impact on Abutters and Community

The Battleship Cove Station is expected to be a net benefit to abutting properties and the Fall River community. Adverse impacts to abutters are expected to be minimal because the adjacent private uses are light commercial/industrial and warehousing. Beneficial impacts to the community would result from revitalizing the existing rail infrastructure and providing a new transportation link to the regional MBTA system. There would be no impact on the existing Ponta Delgada Monument and plaza.

Enhancement of the Property

The Battleship Cove Station would enhance the site by rehabilitating the existing rail infrastructure along this section of the Fall River Secondary and activating the property for public transportation use.

Benefits to the Public Trust Rights in Tidelands or Other Associated Rights

The Battleship Cove Station would benefit public trust rights in filled tidelands at the site by providing new access to the planned passenger rail network and adjacent land. The site contains an open grassy landscaped area adjacent to the Ponta Delgada Monument and plaza, and is open to the public. Access to these areas would not be affected by the station.

Community Activities on the Site

The Battleship Cove Station would increase community activities at the site by providing new access to the regional rail transportation network. The MBTA estimates that approximately 240 passengers would use the station on a daily basis.

Environmental Protection/Preservation

The Battleship Cove Station would meet all local, state, and federal environmental protection and preservation requirements and comply with all applicable regulations.

Public Health and Safety

Providing passenger rail service to the Battleship Cove Station and adjacent downtown Fall River area would result in net benefits to public health and safety resulting from a reduction in single passenger vehicle trips, air pollution, and regional traffic.

General Welfare

The Battleship Cove Station would promote the general welfare by providing new public access to the proposed regional transportation system. MassDOT would use public funds to provide direct and tangible benefits to the residents and visitors in the Battleship Cove area. The station has been designed to promote use by local residents. The potential for traffic impacts has been mitigated by limiting the number of parking spaces at the station site to the required handicapped-accessible spaces only, and by promoting pick-up/drop-off and local bus connections.

Protection of Groundwater

The Battleship Cove Station site is not within an area of known low groundwater, and would not have any adverse impacts to the existing groundwater conditions. The station would be a platform constructed essentially at-grade. No subsurface construction such as a basement, extensive excavation, or groundwater cut-off wall are proposed and no short- or long-term impacts to groundwater are anticipated.

8.6.3.2 Whale’s Tooth Station

Whale’s Tooth Station would be a new train station constructed in New Bedford. It would be located near the intersection of Acushnet Avenue and Hillman Street, near the southern terminus of the New Bedford Main Line. The City of New Bedford has constructed a parking lot on the approximately 14-acre site in anticipation of the South Coast Rail project.

The majority of the Whale’s Tooth Station would be located on landlocked filled tidelands because the station site is entirely separated from the mean high water mark of New Bedford Harbor by interconnected public ways and is at least 250 feet landward of the mean high water mark. The public benefits of the proposed Whale’s Tooth Station are described below.

Purpose and Effect of the Development

The purpose of the Whale’s Tooth Station is to provide new passenger rail access to the New Bedford downtown waterfront area, improving access to the MBTA and regional public transportation network. The station would be adjacent to an existing City of New Bedford parking lot and would be accessible to passengers walking, biking, or driving to the station.

The effects of the development would be:

- Creation of a new public transportation facility providing commuter rail service to the downtown New Bedford area; and
- Activation of filled tidelands for public use for construction of the proposed station and vehicle circulation areas.

Impact on Abutters and Community

The Whale's Tooth Station would result in minimal adverse impacts to abutters and a net benefit to the New Bedford community. Adjacent properties consist primarily of a highway, industrial and trucking properties, vacant land and the Greater New Bedford Career Center; none of these existing uses are likely to be disrupted either by construction or operation of the station.

The New Bedford community at large would benefit by gaining short-term construction related jobs and long-term improved access to the regional transportation network.

Enhancement of the Property

The Whale's Tooth Station would enhance the property by providing new public transportation infrastructure adjacent to an existing paved parking lot.

Benefits to the Public Trust Rights in Tidelands or Other Associated Rights

The Whale's Tooth Station would provide a net benefit to the public trust rights in filled tidelands at the site by providing new access to the planned passenger rail network. The proposed station would enhance the public's use of the landlocked tidelands by increasing utilization of the site and providing access to additional regional transportation options.

Community Activities on the Site

The Whale's Tooth Station would increase community activities at the site by increasing utilization of the existing 14-acre paved parking facility.

Environmental Protection/Preservation

The Whale's Tooth Station construction would meet all local, state and federal environmental protection and preservation requirements and comply with all applicable regulations.

Public Health and Safety

Providing passenger rail service to the site and the downtown New Bedford area would result in net benefits to public health and safety resulting from a reduction in single passenger vehicle trips, air pollution, and regional traffic.

General Welfare

The Whale's Tooth Station would promote the general welfare by providing area residents with new public access to the proposed regional transportation system. MassDOT would use public funds to provide direct and tangible benefits to the residents and visitors to New Bedford. The station's proximity to Route 18 and existing local bus services would take advantage of the existing road network, reducing potential adverse transportation impacts that could result from the South Coast Rail project. The 14-

acre surface parking lot constructed by the City of New Bedford at the site would minimize potential impacts to parking in the vicinity of the site.

Protection of Groundwater

The Whale's Tooth Station site is not within an area of known low groundwater, and would not have any adverse impacts to the existing groundwater conditions. The station would be a single platform constructed at grade. No subsurface construction such as a basement, extensive excavation or groundwater cut-off walls are proposed and no short- or long-term impacts to groundwater are anticipated.

8.6.3.3 Wamsutta Layover Facility

The Wamsutta Layover Facility would be constructed near the southern terminus of the New Bedford Main Line, near the intersection of Wamsutta Street and Herman Melville Boulevard. This location is just north of the Whale's Tooth Station site described above. A portion of the site is currently an active CSX rail yard used for freight. The existing and proposed rail yard is located on top of a capped hazardous waste landfill.

The Wamsutta Layover Facility would be entirely within landlocked tidelands because the site is entirely separated from the water sheet of New Bedford Harbor by Herman Melville Boulevard (a public way in existence on January 1, 1984) and it is located at least 250 feet from the existing mean high water mark.

The public benefits of the proposed Wamsutta Layover Facility are described below.

Purpose and Effect of the Development

The purpose of the Wamsutta Layover Facility is to provide an overnight storage site for equipment needed for the early morning trains departing from New Bedford for Boston. Making use of a terminal layover facility avoids the need to run empty equipment to Boston for overnight storage and then back to New Bedford in the morning for the first northbound train. This would reduce fuel consumption, operation and maintenance costs, and potential environmental impacts with extra late night and early morning trains.

Potential impacts to the community are expected to be minimal because the proposed site is currently an active CSX freight rail yard located along the waterfront in an area dominated by commercial, industrial, and warehouse properties. No air quality effects are anticipated because the preferred rail alternative would use electric motive power. No diesel locomotives or power generation is proposed at the facility.

Impact on Abutters and Community

The Wamsutta Layover Facility would have minimal adverse impacts to abutters, a net benefit to the New Bedford community, and a substantial benefit to abutters in other communities along the New Bedford Main Line and the Stoughton Line. Adverse impacts to abutters are expected to be minimal because the site is currently used as an active freight rail yard and construction would be limited.

The Wamsutta Layover Facility would result in a net benefit to each community adjacent to the New Bedford Main Line and the Stoughton Line because the layover facility would eliminate the need to shuttle empty passenger trains, reducing the potential for noise impacts to these communities.

Enhancement of the Property

The proposed Wamsutta Layover Facility would marginally enhance the property by replacing one rail use with another.

Benefits to the Public Trust Rights in Tidelands or Other Associated Rights

The Wamsutta Layover Facility would improve the capacity of the site to protect the public trust rights in filled tidelands by converting a private freight rail yard to a public transportation facility. As a matter of public safety, the existing use precludes public access for any purpose. While the proposed facility would also prohibit public access to these filled tidelands, the change in use would benefit trust rights in these lands by providing a vital transportation infrastructure facility.

Community Activities on the Site

The Wamsutta Layover Facility would not increase community activities at the site because all public access with continue to be prohibited as a matter of public safety.

Environmental Protection/Preservation

The Wamsutta Layover Facility construction and operation would meet all local, state, and federal environmental protection and preservation requirements and comply with all applicable regulations.

Public Health and Safety

The cap for the soils containing oil and hazardous materials present at the site would remain in place under the Wamsutta Layover Facility. The site would be fenced and lighted to further protect public health and safety. Additionally, siting an overnight layover facility at the New Bedford Main Line terminus would eliminate the need to shuttle empty trains, reducing the potential for noise impacts.

General Welfare

The Wamsutta Layover Facility would promote the general welfare by activating the filled tidelands at the site for a public purpose and reducing extra train trips which would otherwise be required, resulting in fewer potential environmental impacts and substantial saving in fuel and operations and maintenance costs for the life on the project.

Protection of Groundwater

The Wamsutta Layover Facility is not within an area of known low groundwater, and would not have a discernible impact on groundwater because the location is a capped hazardous materials disposal site that is designed to prevent infiltration of surface runoff to groundwater.

8.7 MASSACHUSETTS WETLANDS PROTECTION ACT

This section describes the regulatory context, regulatory requirements, and how the South Coast Rail project would comply with requirements of the Massachusetts Wetlands Protection Act.

8.7.1 Regulatory Context

The South Coast Rail project would require a Variance under the Wetlands Protection Act pursuant to 310 CMR 10.05(10), subject to approval by the MassDEP Commissioner. The Commissioner may waive certain regulations when mitigating measures are proposed that would allow the project to be

conditioned so as to contribute to the public interests in wetlands. The project would also be required to meet Wetlands Protection Act stormwater standards, or require a waiver if certain standards could not be met.

8.7.2 Regulatory Requirements

The South Coast Rail project would not meet the Wetlands Protection Act performance standards for any of the wetland resource areas affected by the project because the proposed project would exceed the area (acreage) thresholds for alteration, would result in short- or long-term impacts to the habitat of state-listed rare wildlife species, and would not provide compensatory mitigation in strict accordance with the performance standards for Bordering Vegetated Wetland (BVW) or, potentially, other resource areas.

MassDOT would seek a variance under the Wetlands Protection Act, in accordance with 310 CMR 10.05(10), for wetland alteration and would comply with all applicable stormwater regulations. This section describes the applicable variance criteria and stormwater management standards.

The Wetlands Protection Act regulations establish performance standards for work proposed within the wetland resource areas, and require review of any work proposed within 100 feet of a wetland resource to determine if that work will result in the alteration of wetland resources. "Alteration" is defined to "include a change in vegetation, hydrology, or water quality of the wetland."

Three criteria of the Wetlands Protection Act regulations (310 CMR 10.05) must be met to grant a Variance request:

- Demonstrate that there are no reasonable conditions or alternatives that would allow the project to proceed in compliance with the wetlands regulations;
- Propose mitigation measures that will allow the project to be conditioned so as to contribute to the protection of the interests identified in the Wetlands Protection Act; and
- Demonstrate that the variance is necessary to accommodate an overriding community, regional, state or national public interest, or that it is necessary to avoid an Order that so restricts the use of property as to constitute an unconstitutional taking of property without compensation

8.7.3 Regulatory Compliance

The Stoughton Alternative would comply with the Wetlands Protection Act Variance criteria and stormwater standards, as described below.

8.7.3.1 Variance Criteria

The project would directly impact wetlands as a result of reconstructing the existing active and inactive rail lines. In some cases, it is necessary to widen the existing berm where sections of multiple tracks are planned. Retaining walls, regraded existing slopes, and replaced or upgraded culverts and bridges will all have permanent and/or temporary impacts on wetlands.

The Stoughton Electric Alternative would impact 9.6 acres of BVW, exceeding the 5,000-square foot threshold of area of alteration to BVW and requiring the Commissioner of MassDEP to issue a variance

from the performance standards of the Wetlands Protection Act regulations. The variance regulation allows performance standards to be waived if the following three criteria are met.

Criterion 1: There are no reasonable conditions or alternatives that would allow the project to proceed in compliance with 310 CMR 10.21 through 10.60.

An extensive alternatives analysis was undertaken for the South Coast Rail project, as described in Chapter 3. Seven alternatives were examined to determine whether they could meet the project purpose and would be practicable to construct and operate. Six of the alternatives were dismissed from further consideration because they could not meet the project purpose and/or would not be practicable to construct and operate. MassDOT has identified the Stoughton Alternative as the Preferred Alternative, and was directed by the Executive Office of Energy and Environmental Affairs to advance the Stoughton Electric Alternative. This alternative best meets the project purpose and would be practicable to construct and operate.

None of the alternatives considered could be constructed in strict compliance with the Wetlands Protection Act regulations; all of the alternatives would have unavoidable impacts to wetland resource areas that would exceed the relevant performance standards in 310 CMR 10.21 through 10.60, as documented in Chapter 4.16, *Wetlands*. As noted above, the Stoughton Electric Alternative would impact 9.6 acres of BVW, well in excess of the 5,000 square foot threshold.

Although the loss of wetlands has and will continue to be minimized through preliminary and final design, there are no reasonable conditions that would allow the project to proceed in compliance with these regulations due to the length of the corridor and the proximity of wetlands to the railbed.

Criterion 2: Mitigating measures are proposed that will allow the project to be conditioned so as to contribute to the protection of the interests identified in M.G.L. c.131, §40.

Proposed mitigation measures are described in Chapter 7, *Proposed Mitigation Measures and MassDOT Proposed Section 61 Findings*, as well as in Chapter 4.16, *Wetlands*. In summary, wetland restoration or establishment at up to seven potential sites is proposed to meet state 2:1 mitigation goals by providing mitigation of at least:

- 19.2 acres of wetlands to offset impacts to BVW;
- 1.9 acres of wetlands to offset impacts to land under water (LUW); and
- 6.7 acres of wetlands or compensatory flood storage to offset impacts to bordering land subject to flooding (BLSF). Final design of BLSF mitigation will also assess the volume of compensatory storage to be provided.

While the areas under consideration for mitigation are larger than the required mitigation, MassDOT would commit to constructing the amount of mitigation necessary to satisfy the required mitigation goals. At the current level of design for the project, mitigation plans are not sufficiently accurate to determine the amount of wetland establishment that is practicable in a given area and will likely change when detailed field conditions are evaluated. The proposed mitigation plans cover larger areas than are required and allow for changes or reductions in the area of wetland mitigation from unknown site constraints.

MassDOT would further refine the mitigation measures during preliminary and final design. The proposed wetland mitigation plan identifies specific locations to serve as suitable wetland resource mitigation areas, demonstrates its ability to successfully replicate wetland functions and ecological values, and provides wetland mitigation at a ratio of 2:1 or greater.

In addition, a list of potential wetland preservation sites has been developed to identify candidates for wetland preservation to address USACE-specific mitigation requirements of state requirements. Wetland preservation is one of a suite of mitigation options to meet the USACE-specific mitigation requirements, in addition to the wetland establishment and restoration discussed above.

Criterion 3: The variance is necessary to accommodate an overriding community, regional, state or national public interest; or that it is necessary to avoid an Order that so restricts the use of the property as to constitute an unconstitutional taking without compensation.

Regulation 310 CMR 10.05(10) provides that the Commissioner may waive the application of the regulations if it is found "that the variance is necessary to accommodate an overriding community regional, state or national public interest ..." This first element of the criterion requires a showing that the project is being pursued by, or under the auspices of, a public authority or a private entity found to be serving a public function. Since the MBTA is pursuing this project, the first element of this test is met in that the applicant is a public entity pursuant to MGL Chapter 161A, Section 2.

The second element of this criterion requires that the applicant show that the project is one of such unusual merit or necessity in serving a public interest that it overrides MassDEP's interest in enforcing its wetland regulations. The public interest served by the Stoughton Electric Alternative is that it would address the need for public transportation from the South Coast region to Boston and provide benefits to the South Coast region in terms of public transit equity, service distribution and ridership, air quality and climate change improvements, and opportunities for smart growth and sustainable development as an alternative to sprawl.

This FEIS/FEIR documents the need for transportation improvements in the South Coast region (see Chapter 2, *Purpose and Need*). The South Coast Rail project is an initiative of MassDOT and the MBTA who have defined its purpose as "to more fully meet the existing and future demand for public transportation between Fall River/New Bedford and Boston, and to enhance regional mobility, while supporting smart growth planning and development strategies in affected communities." The need for the project establishes the public benefits that would be met. The current transportation system serving the South Coast region is inadequate to meet the current needs of the region and will not meet the future demand placed upon it, as indicated by increasing traffic congestion and accidents. Major transportation needs and deficiencies that would be addressed by the South Coast Rail project include:

- Lack of transportation capacity to downtown Boston;
- Congestion on highway and transit facilities serving the region; and
- Air quality that does not meet federal Clean Air Act standards.

Overriding public interests that arise from these from a MEPA perspective include:

- Improving regional air quality;

- Adding transportation capacity between Fall River, New Bedford, and downtown Boston;
- Reducing congestion on highway and transit facilities;
- Improving travel times;
- Improving regional mobility;
- Improving access to jobs;
- Providing equity to Environmental Justice populations; and
- Promoting smart growth planning.

The commuter rail would increase the number of travelers that would choose to use public transit for work trips from the South Coast to Boston and Cambridge and reduce the vehicle miles of travel by automobiles. The improvements to public transportation services in the South Coast Rail corridor are consistent with regional goals that envision diversion of auto trips to transit, and rely on improved transit services to provide more attractive and lower-impact travel choices to peak period travelers as the regions highway system becomes increasingly congested due to the growth in automobile travel.

Transportation benefits of the proposed commuter rail line include a reduction in automobile trips to access transit (since feeder bus service would provide rides to new stations and current South Coast residents accessing commuter rail in Stoughton will be able to walk to or make a shorter trip to closer stations); fewer side trips made by automobile commuters during the day since they would not be driving their cars; and diversion of commuters from automobile or other transit services that would reduce the demand for parking in downtown Boston and at major transit stations.

Air quality would benefit from the South Coast Rail project, as described in Chapter 4.9. Vehicle miles traveled (VMT) would be reduced as commuters shift travel mode from private automobiles to public transit, reducing emissions from cars. The electric motive power of the trains would not emit air pollutants, and emissions from remote power plants to produce the electric power would be lower than those of diesel-powered trains. The mode shift would also reduce greenhouse gas emissions, with less of an impact on climate than the No-Build Alternative.

The project would also support smart growth development, reducing sprawl as compared to the No-Build Alternative. The new station locations were selected in part to support TOD, and station sites are near development blocks. The Corridor Plan outlines measures that the municipalities served by the South Coast Rail may take, with support from the Commonwealth, to promote smart growth development in selected areas and preserve open space in other areas. The Commonwealth will support municipalities through incentives and technical assistance. Executive Order 525 directs state agencies to implement Corridor Plan when making decisions affecting the South Coast region.

On November 8, 2002, MassDEP issued a Variance under its Wetlands Protection Act regulations for the Greenbush Project. Like the proposed South Coast Rail project, the 2002 project was undertaken to improve the regional transportation system. The reasoning behind the 2002 MassDEP Variance Decision remains current and applicable to the South Coast Rail project now proposed, even though the South Coast Rail project is not a component of the State Implementation Plan (SIP, for air quality). The 2002 MassDEP Variance Decision for the Greenbush Project concluded that:

> *"In sum, the proposed project has demonstrated an overriding public interest because it will provide additional transit services in the South Shore region, reduce automobile use and vehicle miles traveled, and allow for compliance with the [Central Artery/Tunnel] commitments and the SIP."*

As MassDEP has found in this previous Variance, transit improvements constitute an overriding public need. The South Coast Rail project would improve transit and therefore serves an overriding public interest.

8.7.3.2 Stormwater Management Standards

The Stoughton Alternative is currently at a conceptual level of design. The preliminary designs for the track, stations, and layover facilities have been developed to demonstrate that the project would comply with the MassDEP Stormwater Management Standards. During the final design, each element of the South Coast Rail project would be developed in full compliance with the Standards. Based on the current level of design, the Standards and how the South Coast Rail project would comply with each one are provided below.

Standard 1: No new stormwater conveyances may discharge untreated stormwater directly to or cause erosion in wetlands or waters of the Commonwealth.

BMPs proposed upgradient from any new discharge have been designed in accordance with the Massachusetts Stormwater Handbook and provide the required treatment volume. All proposed stormwater outlets and conveyances have been designed to not cause erosion or scour to wetlands or receiving waters.

Standard 2: Stormwater management systems shall be designed so that post-development peak discharge rates do not exceed pre-development peak discharge rates. This Standard may be waived for discharges to land subject to coastal storm flowage as defined in 310 CMR 10.04.

Stormwater BMPs with volume storage are proposed at each location where post-development peak discharges would require attenuation. Sites with discharges to coastal waters (Fall River Depot Station, Battleship Cove Station, Whale's Tooth Station, Weaver's Cove East Layover Facility, and Wamsutta Layover Facility) may waive this standard and are not required to incorporate attenuation structures.

Standard 3: Loss of annual recharge to ground water shall be eliminated or minimized through the use of infiltration measures including environmentally sensitive site design, low impact development techniques, stormwater best management practices, and good operation and maintenance. At a minimum, the annual recharge from the post-development site shall approximate the annual recharge from pre-development conditions based on soil type. This Standard is met when the stormwater management system is designed to infiltrate the required recharge volume as determined in accordance with the Massachusetts Stormwater Handbook.

Groundwater recharge requirements would be met for each project element. Environmentally Sensitive Site Design (ESSD) techniques and LID features have been incorporated into the conceptual design of each station site and layover facility. ESSD techniques include reducing impervious area by removing unnecessary pavement, maintaining existing drainage patterns, and maintaining existing mature vegetation. LID features include disconnecting runoff from impervious surfaces, using sheet flow and

surface conveyances instead of closed drainage systems, and promoting groundwater recharge through bioretention and infiltration basins.

Standard 4: Stormwater management systems shall be designed to remove 80 percent of the average annual post-construction load of Total Suspended Solids (TSS). This Standard is met when:

- Suitable practices for source control and pollution prevention are identified in a long- term pollution prevention plan, and thereafter are implemented and maintained;
- Structural stormwater BMPs are sized to capture the required water quality volume determined in accordance with the Massachusetts Stormwater Handbook; and
- Pretreatment is provided in accordance with the Massachusetts Stormwater Handbook.

Structural practices such as deep sump catch basins with hoods, oil/grit separators, and gravel and grass filter strips have been incorporated as appropriate in each site design in order to provide pretreatment of stormwater flows. Bioretention swales, bioretention basins, and infiltration basins have been incorporated as appropriate in each site design to provide treatment that meets or exceeds the 80 percent TSS removal requirement.

The only location where the water quality volume and 80 percent TSS removal requirement would not be met is along the Hockomock Swamp Trestle. Runoff from the trestle would be treated to the extent practicable and would meet all of the requirements of the *de minimis* standard described in Volume 3 of the Massachusetts Stormwater Handbook.

In order to comply with the on-going requirements of this standard, a long-term SWPPP would be included as part of the final design.

Standard 5: For land uses with higher potential pollutant loads, source control and pollution prevention shall be implemented in accordance with the Massachusetts Stormwater Handbook to eliminate or reduce the discharge of stormwater runoff from such land uses to the maximum extent practicable. If through source control and/or pollution prevention all land uses with higher potential pollutant loads cannot be completely protected from exposure to rain, snow, snow melt, and stormwater runoff, the proponent shall use the specific structural stormwater BMPs determined by the Department to be suitable for such uses as provided in the Massachusetts Stormwater Handbook. Stormwater discharges from land uses with higher potential pollutant loads shall also comply with the requirements of the Massachusetts Clean Waters Act, M.G.L. c. 21, §§ 26-53 and the regulations promulgated thereunder at 314 CMR 3.00, 314 CMR 4.00 and 314 CMR 5.00.

Three sites qualify as Land Uses with Higher Potential Pollutant Loads (LUHPPLs): North Easton Station, Weaver's Cove East Layover Facility, and Wamsutta Layover Facility. These sites incorporate structural stormwater BMPs such as deep sump catch basins with hoods, oil/grit separators and sediment forebays. The layover facilities also incorporate drip pans beneath the layover tracks to catch drips or spills from the trains stored at the facility.

Appropriate source control and pollution prevention measures must be documented in a post-construction SWPPP. This plan would be completed in conjunction with the NOI for authorization of stormwater discharges under the NDPES Multi-Sector General Permit for Industrial Activities, prior to stormwater discharges from the layover facilities.

Standard 6: Stormwater discharges within the Zone II or Interim Wellhead Protection Area of a public water supply and stormwater discharges near or to any other critical area require the use of the specific source control and pollution prevention measures and the specific structural stormwater best management practices determined by the Department to be suitable for managing discharges to such areas as provided in the Massachusetts Stormwater Handbook. A discharge is near a critical area, if there is a strong likelihood of a significant impact occurring to said area, taking into account site-specific factors. Stormwater discharges to Outstanding Resource Waters and Special Resource Waters shall be removed and set back from the receiving water or wetland and receive the highest and best practical method of treatment. A "storm water discharge" as defined in 314 CMR 3.04(2)(a)1 or (b) to an Outstanding Resource Water or Special Resource Water shall comply with 314 CMR 3.00 and 314 CMR 4.00. Stormwater discharges to a Zone I or Zone A are prohibited unless essential to the operation of a public water supply.

Stormwater discharges to ORWs would receive treatment and would be set back from the receiving water to the maximum extent practicable. Discharges to ORWs are limited to locations along the Hockomock Swamp Trestle and along track segments located near vernal pools. No discharges are proposed within a Zone 1 or Zone A of a public water supply. Appropriate treatments for each location would be selected during final design as part of detailed grading plans and drainage analysis.

Standard 7: A redevelopment project is required to meet the following Stormwater Management Standards only to the maximum extent practicable: Standard 2, Standard 3, and the pretreatment and structural best management practice requirements of Standards 4, 5, and 6. Existing stormwater discharges shall comply with Standard 1 only to the maximum extent practicable. A redevelopment project shall also comply with all other requirements of the Stormwater Management Standards and improve existing conditions.

All but three of the station sites (North Easton Station, Taunton Depot Station, and Freetown Station) and both of the layover facilities qualify as redevelopment projects. The station sites where new parking lots are proposed (Raynham Park and Taunton) and the Weaver's Cove East Layover Facility have been designed to fully comply with all of the stormwater standards.

Standard 8: A plan to control construction related impacts including erosion, sedimentation and other pollutant sources during construction and land disturbance activities (construction period erosion, sedimentation, and pollution prevention plan) shall be developed and implemented.

The project would obtain coverage under the NPDES General Permit for Construction Activities prior to the start of earthmoving activities. A construction-period SWPPP would be developed during final design as part of the NOI submittal. Recommended construction period BMPs are described in Chapter 4.17 of this FEIS/FEIR.

Standard 9: A long-term operation and maintenance plan shall be developed and implemented to ensure that stormwater management systems function as designed.

MassDOT would develop a detailed Operations and Maintenance Plan (O&M Plan) during final design as part of the NOI submittal.

Standard 10: All illicit discharges to the stormwater management system are prohibited.

Proposed stations and layover facilities have been designed so that they are in full compliance with current standards. In locations where previous development has occurred, storm drainage structures remaining from those developments would be removed within the redevelopment area. New sanitary facilities at the two layover facilities would be designed in accordance with the sanitary code.

8.8 CLEAN WATER ACT SECTION 401—MASSACHUSETTS CLEAN WATER ACT

This section describes the regulatory context, regulatory requirements, and how the South Coast Rail project would comply with requirements of Section 401 of the Clean Water Act as administered by MassDEP under the Massachusetts Clean Water Act and implementing regulations.

8.8.1 Regulatory Context

Section 401 of the Clean Water Act (33 U.S.C. 1341) requires any applicant for a federal license or permit to conduct any activity that may result in a discharge of a pollutant into waters of the United States to obtain a certification from the state in which the discharge originates or would originate, that the discharge would comply with the applicable (i.e., Commonwealth of Massachusetts) effluent limitations and water quality standards.

Under the Clean Water Act, MassDEP is required to issue Water Quality Certifications for projects that result in discharge of fill to a wetland or waterbody, pursuant to the Massachusetts Clean Water Act (MGL Ch. 21 § 26-53). MassDEP executes its responsibilities pursuant to Section 401 under the Massachusetts Clean Water Act (M.G.L. c 21 §§ 26-53) and is the final arbiter as to whether a water quality certification will be issued, denied, or waived. The Order of Conditions issued by local conservation commissions automatically assumes the issuance of a water quality certificate for projects impacting less than 5,000 square feet of wetlands. This project would require MassDOT to obtain an Individual Water Quality Certificate from MassDEP as impacts would exceed 5,000 square feet. However, because the project cannot meet two performance criteria, as described in Section 8.8.3, MassDOT will seek a Variance from certification.

8.8.2 Regulatory Requirements

Massachusetts regulations[5] cover construction, operation, and maintenance of activities related to dredged or fill material within waters of the United States within the Commonwealth of Massachusetts, and discharge of waters to wetlands and waterways subject to state and federal jurisdiction if a NPDES permit is required for a project. Any activity that would result in a discharge of dredged material, dredging, or dredged material disposal greater than 100 cubic yards that is also subject to federal regulation under Clean Water Act Section 404 must obtain a Clean Water Act Section 401 Water Quality Certification.

There are seven criteria for the evaluation of applications for discharge of dredge or fill material (314 CMR 9.06):

[5] 314 CMR 9.00, 401 Water Quality Certification for Discharge of Dredged or Fill Material, Dredging, and Dredged Material Disposal in Waters of the United States Within the Commonwealth. http://www.mass.gov/dep/service/regulations/314cmr09.pdf, accessed 28 June 2012.

- No discharge of dredged or fill material shall be permitted if there is a practicable alternative to the proposed discharge which would have less adverse impact on the aquatic ecosystem;

- No discharge of dredged or fill material shall be permitted unless appropriate and practicable steps have been taken which would minimize potential adverse impacts to the bordering or isolated vegetated wetlands or land under water, including a minimum of 1:1 restoration or replication of isolated or bordering wetlands;

- No discharge of dredged or fill material shall be permitted to ORWs, except for the activities specified in 314 CMR 9.06(3)(a) through (I), which remain subject to an alternatives analysis and other requirements of 314 CMR 9.06;

- Discharge of dredged or fill material to an ORW specifically identified in 314 CMR 4.06(1)(d) (e.g., vernal pools, within 400 feet of a water supply reservoir and any other area so designated) is prohibited as provided therein unless a variance is obtained under 314 CMR 9.08;

- No discharge of dredged or fill material is permitted for the impoundment or detention of stormwater for the purposes of controlling sedimentation or other pollutant attenuation;

- Stormwater discharges shall be provided with BMPs to attenuate pollutants and provide a set back from receiving water or wetland; and

- No discharge of dredged or fill material shall be permitted in the rare circumstances where the activity meets the criteria for evaluation but would result in substantial adverse impacts to the physical, chemical, or biological integrity of surface waters of the Commonwealth.

8.8.3 Regulatory Compliance

The Stoughton Alternative would comply with five of the seven criteria outlined above for the discharge of dredged or fill material within waterways or wetlands.

- As described in Section 8.2.3.1 of this chapter, there are no practicable alternatives to the Stoughton Electric Alternative that would have less adverse impact on aquatic ecosystems.

- As described in Chapter 7.3, all appropriate and practicable steps have been taken to minimize adverse impacts to bordering or isolated vegetated wetlands and land under water. The proposed mitigation measures described in Section7.4.9 include the creation or restoration of up to 89 acres of wetlands at up to seven sites, at ratios determined in consultation with MassDEP, USACE, and the EPA, depending on cover type, for no net loss of wetland functions and values. Additionally, MassDOT will select and preserve wetlands at Priority Preservation Area sites if the area of federal wetland mitigation needed would not be fully achieved by wetland establishment and restoration.

- As described in Chapter 4.17, *Water Resources*, stormwater discharges would be managed in accordance with Massachusetts Stormwater Management Regulations. No dredged or fill material would be discharged into wetlands for the impoundment or detention of stormwater for the purposes of controlling sedimentation or other pollutant attenuation.

- Also as described in Chapter 4.17, stormwater discharges would be provided with BMPs to attenuate pollutants and would be set back from receiving waters and wetlands, in accordance with Massachusetts Stormwater Management Regulations.

- The South Coast Rail project would not result in substantial adverse impacts to the physical, chemical, or biological integrity of surface waters of the Commonwealth.

The Stoughton Alternative would require fill in ORWs (vernal pools) and would not meet either of the performance standards prohibiting the discharge of dredged or fill material in ORWs. This alternative would also require fill in wetlands associated with Fall Brook, a public water supply ORW. MassDOT would seek a Variance from Clean Water Act Section 401 Certification, in accordance with 314 CMR 9.08, for placement of fill into ORWs. The MassDEP Commissioner may issue a Variance of the criteria for evaluation of Section 401 Certification applications if the applicant demonstrates that:

- All reasonable measures have been proposed to avoid, minimize, and mitigate adverse effects on the environment; and

- The Variance is justified by an overriding public interest or necessary to avoid a certification that so restricts the use of property as to constitute an unconstitutional taking without compensation.

The MassDEP Commissioner may consolidate variance decisions under 314 CMR 9.00 (Section 401 Certification regulations), 310 CMR 10.36 and 10.58 (Wetlands Protection Act regulations), and 310 CMR 9.21 (Waterways regulations). These criteria are met pursuant to the description of the Variance from Wetlands Protection Act regulations provided in Section 8.7.3.1. The proposed project avoids impacts to the extent practicable, has minimized impacts, will mitigate for unavoidable wetland impacts, and serves an overriding public interest.

8.9 MASSACHUSETTS PUBLIC WATERFRONT ACT LICENSE (CHAPTER 91)

This section describes the regulatory context, regulatory requirements, and how the South Coast Rail project would comply with requirements of the Massachusetts Public Waterfront Act, as codified in MGL Chapter 91.

8.9.1 Regulatory Context

Chapter 91 is the Commonwealth's primary tool for protection and promotion of public use of its tidelands and other waterways. The South Coast Rail project would require approvals under the waterways licensing program of Chapter 91 and the waterways regulations at 310 CMR 9.00 for construction, reconstruction, minor modifications to existing structures, changes in use of filled tidelands and culvert and bridge replacement within non-tidal rivers and streams. No work is proposed within flowed tidelands.

Chapter 91 Sections 1 through 63 require a waterways license, issued by MassDEP, for work on or use of fill or structures within the geographic jurisdiction of Chapter 91. That jurisdiction extends to:

- All waterways of the Commonwealth subject to tidal action;

- All filled tidelands up to and including the historic high water mark, except for landlocked tidelands as defined by Chapter 168 of the Acts of 2007; and
- Navigable portions of non-tidal rivers and streams upon which public funds have been spent for channel improvement, flood control, or stream clearance.

8.9.2 Regulatory Requirements

Chapter 91 regulations at 310 CMR 9.31 establish minimum licensing standards for projects requiring a new Waterways license under Chapter 91. They include the following:

- **Basic Requirements**—The regulations at 310 CMR 9.31 establish the basic licensing requirements for all projects subject to Chapter 91. This regulation requires compliance with all applicable standards contained in 310 CMR 9.32 through 310 CMR 9.40.
- **Proper Public Purpose Requirements**—The regulations at 310 CMR 9.31(2) require MassDEP to determine that all projects requiring a Waterways license meet a proper public purpose which provides greater benefit than detriment to the inherent public rights in said land. Water Dependent Use projects are assumed by 310 CMR 9.31(2)(a) to meet this standard. Non-water dependent use projects must comply with the standards at 310 CMR 9.51 through 310 CMR 9.55, as applicable to demonstrate they serve a proper public purpose.

The South Coast Rail project includes 22 locations where the track crosses a non-tidal river or stream subject to the jurisdiction of Chapter 91, and are therefore considered infrastructure crossing facilities per 310 CMR 9.02. The proposed Weaver's Cove East Layover Facility is also subject to licensing under Chapter 91 because it meets the regulatory definition of an infrastructure facility provided in 310 CMR 9.02.

8.9.3 Regulatory Compliance

This section describes the South Coast Rail project elements subject to licensing or other Chapter 91 approvals, their water dependency and provides a summary of how each would comply with the applicable waterways regulations at 310 CMR 9.00 and the municipal harbor planning process described at 301 CMR 23.00. The Stoughton Alternative includes existing track, ballast, and drainage structures located within filled tidelands subject to jurisdiction under 310 CMR 9.04(2), and bridges and culverts crossing non-tidal rivers and streams subject to jurisdiction under 310 CMR 9.04(1)(e). Many of the existing bridge crossings are presently licensed under Chapter 91. The smaller stream crossings are generally not licensed. The proposed Weaver's Cove East Layover Facility is also not yet licensed under Chapter 91.

8.9.3.1 Infrastructure Crossing Facilities

The South Coast Rail project includes 22 bridges or culverts that span a Chapter 91 jurisdictional water body from one bank to the opposite bank.[6] These crossings therefore meet the regulatory definition of infrastructure crossing facilities provided in 310 CMR 9.02. Table 8.9-1 summarizes the proposed bridge and culvert replacements that would be subject to Chapter 91.

[6] The bridge over the Taunton River at MP 34.73 crosses a small cove along the west side of the river and does not span the river itself.

Table 8.9-1 Proposed Bridge and Culvert Replacement Subject to Chapter 91

Waterbody	Presently Licensed	Proposed Alteration	Anticipated Chapter 91 Application
Pequit Brook	No	No change to historic arch structure. Addition of second track, expansion of footprint over waterway, no change in navigability.	New License
Beaver Meadow Brook	No	No change to abutment location. New structure proposed above or adjacent to existing historic arch.	New License
Whitman Brook	No	New abutments would be constructed behind existing abutments, which would then be removed.	Maintenance
Black Brook (CV-ST 10.95)	No	Replacement of existing culvert, not presently designed.	Maintenance
Unnamed tributary to Black Brook (CV-ST 11.59)	No	Replacement of existing culvert, not presently designed.	Maintenance
Black Brook (CV-ST 12.68)	No	New bridge would be constructed to replace washed out culvert.	New License (if deemed navigable)
Unnamed tributary to Pine Swamp Brook (CV-ST 16.00)	No	Replacement of existing culvert, not presently designed.	Maintenance
Pine Swamp Brook (CV-ST 17.37)	No	Replacement of existing culvert, not presently designed.	Maintenance
Taunton River	Lic. 3118 Oct. 19, 1906	Reconstruction of existing crossing outside existing structure, removal of existing abutments.	New License or License Amendment
Taunton River	Lic. 3118 Oct. 19, 1906	Existing piles to be replaced by one mid-stream concrete pier. New abutments to be constructed outside existing structure which would then be removed.	New License or License Amendment
Taunton River	Lic. 2909 Nov. 1, 1904	Existing piles to be replaced by one mid-stream concrete pier. New abutments to be constructed outside existing structure which would then be removed.	New License or License Amendment
Mill River	Lic. 3118 Oct. 19, 1906	Reconstruction of existing crossing outside existing structure, removal of existing abutments.	New License or License Amendment
Taunton River	Yes	Bridge replacement: existing piles would be removed and one new cast-in-place concrete pier would be constructed in the center span. New abutments would be constructed behind existing abutments which would then be removed.	New License
Unnamed tributary to Cotley River (CV-NB 14.52)	No	Replacement/expansion of existing culvert.	New License
Cotley River	No	Bridge replacement: New abutments would be constructed behind the existing abutments, which would then be	New License

Waterbody	Presently Licensed	Proposed Alteration	Anticipated Chapter 91 Application
		removed.	
Cotley River	No	Bridge replacement: New abutments would be constructed behind the existing abutments, which would then be removed.	New License
Unnamed tributary to Cedar Swamp River (CV-NB 17.89)	No	Replacement of existing culvert, not presently designed.	Maintenance
Assonet River	No	Bridge replacement: existing piles to be replaced by one mid-stream concrete pier. New abutments to be constructed outside existing structure which would then be removed.	New License
Cedar Swamp River	No	New abutments would be constructed behind the existing abutments, which would then be removed.	New License
Unnamed tributary to Fall Brook	No	Replacement of existing culvert, not presently designed.	Maintenance
Fall Brook	No	Bridge replacement: new abutments would be constructed behind existing abutments, which would then be removed.	Minor modification
Unnamed (CV-NB 26.96)	No	Replacement of existing culvert, not presently designed.	Maintenance

The 22 locations where the track crosses a non-tidal river or stream subject to the jurisdiction of Chapter 91 meet the regulatory definition of Infrastructure Crossing and must comply with three Chapter 91 licensing requirements (water dependence, public purpose, and reconstruction) as well as the basic requirements, as described in the following subsections.

Water Dependence

Pursuant to 310 CMR 9.12(d), infrastructure crossing facilities may be determined to be water dependent by MassDEP only upon a finding by the Secretary that such facilities cannot be located away from such waters. The Stoughton Alternative includes use of existing railroad corridors which require numerous bank-to-bank crossings of jurisdictional non-tidal rivers and streams. A range of alternatives were previously considered and all would require numerous non-tidal river and stream crossing to extend passenger rail service as dictated by the project.

MassDOT has requested that the Secretary determine that all existing and proposed bank-to-bank rail crossings of jurisdictional non-tidal rivers cannot be relocated away from inland waters, authorizing MassDEP to find them to be water dependent pursuant to 310 CMR 9.12(2)(b).

Public Purpose

310 CMR 9.31(2) requires projects on tidelands and Great Ponds to serve a proper public purpose which provides greater benefit than detriment to the rights of the public. Water-dependent use projects are presumed to meet this requirement under the provisions of 310 CMR 9.31(2)(a). All of the existing and

proposed infrastructure crossing facilities over non-tidal rivers and streams are presumed to meet this standard.

Proposed Reconstruction

As listed in Table 8.9-1, new Chapter 91 Licenses are anticipated where there would be substantial structural alteration (enlargement) of an existing exempt structure to accommodate a second track. New or amended licenses would be required when there would be substantial structural alteration to an existing structure in terms of size, configuration, materials and design and fabrication parameters, but the number of tracks would not change. Reconstructing structures would be considered “maintenance” where it includes replacement of an existing exempt structure needed to restore the serviceability of existing railroad infrastructure without substantial enlargement.

Basic Requirements

The list below provides the applicable Basic License Requirements referenced in 310 CMR 9.31(1) and identifies the standards that apply to the proposed non-tidal river and stream crossings listed in Table 8.9-1 and provides a rationale for compliance. Only standards applicable to the South Coast Rail project are included.

310 CMR 9.31(1)(a): No new fill is permitted in flowed tidelands for non-water dependent use projects.

All existing and proposed South Coast Rail crossings are water dependent infrastructure crossing facilities pursuant to 310 CMR 9.02 and 310 CMR 9.12(2)(d).

310 CMR 9.31(1)(b): Projects must comply with all applicable state environmental protection requirements.

The South Coast Rail project would obtain all required state and federal permits and approvals.

310 CMR 9.31(1)(c): Projects must comply with applicable local zoning and Municipal Harbor Plans (MHPs).

Section 8.9.3.3 describes the South Coast Rail project’s consistency with local economic plans and MHPs. Although two South Coast Rail project elements (Wamsutta Layover Facility and Whale’s Tooth Station) are within an MHP area, they are not subject to Chapter 91 licensing as they would be located on landlocked filled tidelands.

310 CMR 9.31(1)(d): This standard prohibits projects from significantly interfering with:

- Public rights of navigation which exist in all waterways;
- Free passage over and through the water; and
- Access to town landings.

Existing culverts along the South Coast Rail corridor crossing non-tidal rivers and streams provide limited navigation. The existing bridges are generally licensed structures and provide passage for small vessel navigation. Proposed culvert and bridge improvements would maintain or enhance existing navigability at jurisdictional crossings.

310 CMR 9.31(1)(e): The project shall preserve the availability and suitability of tidelands, Great Ponds and other waterways that are in use for water-dependent purposes, or which are reserved primarily as locations for maritime industry or other specific types of water-dependent use. The project shall not significantly interfere with littoral or riparian property owners' rights to approach their property from a waterway and to approach the waterway from said property.

The South Coast Rail project does not include any new non-tidal river and stream crossings and therefore would not significantly interfere with any littoral or riparian property owners' rights of access. Existing crossings would be maintained or upgraded to support passenger rail traffic. Where feasible, upgrades would widen culverts to improve wildlife passage resulting in a net benefit to navigation.

310 CMR 9.31(1)(e): The project shall not significantly disrupt any water-dependent use in operation, as of the date of license application, at an off-site location proximate to the vicinity of the project site.

The South Coast Rail project would enhance the capacity for the existing water-dependent infrastructure crossing facilities to support public transportation and this public service project.

310 CMR 9.31(1)(e): The project shall not displace any water-dependent use that occurred on the site within the last five (5) years.

The existing South Coast Rail railroad crossings are all located on land owned and/or operated as a railroad for many years. The project would restore, maintain or enhance these existing water-dependent infrastructure crossing facilities.

8.9.3.2 Infrastructure Facility

The proposed Weaver's Cove East Layover Facility is the only project infrastructure facility potentially subject to licensing under Chapter 91. This facility meets the regulatory definition in 310 CMR 9.02:

> *"Infrastructure Facility means a facility which produces, delivers, or otherwise provides electric, gas, water, sewage, transportation, or telecommunications services to the public."*

The Weaver's Cove East Layover Facility compliance with applicable Chapter 91 licensing requirements is provided below.

Water Dependency

The Weaver's Cove East Layover Facility would be a non-water dependent infrastructure facility, as defined by 310 CMR 9.55. This facility does not meet the regulatory criteria at 310 CMR 9.12(2) defining water-dependent use projects because it does not require access to or located in tidal or inland waters.

MassDEP has confirmed that the Weaver's Cove East Layover Facility would be subject to licensing under 310 CMR 9.55 (Standards for Nonwater-Dependent Infrastructure Facilities.)

Public Purpose

310 CMR 9.31(2) requires projects on tidelands and Great Ponds to serve a proper public purpose which provides greater benefit than detriment to the rights of the public. Non-water dependent projects are reviewed under the requirements of 310 CMR 9.31(2)(b).

The Weaver's Cove East Layover Facility would comply with the requirements of 310 CMR 9.55 and the additional standards contained in 310 CMR 9.54, and is consistent with the applicable programmatic policies and management principles of the Massachusetts CZMP, which is described in Section 8.5.

Standards for Non-Water Dependent Infrastructure Facilities

The regulations at 310 CMR 9.55 waive the provisions of 310 CMR 9.51 through 310 CMR 9.53 for non-water dependent infrastructure facilities. The regulations at 310 CMR 9.55(1) requires projects to include mitigation and/or compensation measures as deemed appropriate by MassDEP to ensure that all feasible measures are taken to avoid or minimize detriments to water-related interest of the public.

The proposed Weaver's Cove East and Wamsutta layover facilities meet the definition of non-water dependent use infrastructure facilities and are therefore potentially subject to 310 CMR 9.55. The proposed Wamsutta Layover Facility would be constructed on landlocked filled tidelands and would not be subject to licensing. The proposed Weaver's Cove East Layover Facility would be located on filled tidelands and is subject to licensing and review under 310 CMR 9.55.

The public interests protected by 310 CMR 9.55(1) and listed below describe how the proposed Weaver's Cove East Layover Facility would comply with each.

Protection of Maritime Commerce, Industry, Recreation and Associated Public Access

The proposed Weaver's Cove East Layover Facility site is undeveloped and does not provide public access to the shoreline due to the presence of the existing Fall River Secondary rail corridor. The site is separated from the Taunton River by the Fall River Secondary and does not support any maritime commerce or industry.

Protection, Restoration, and Enhancement of Living Marine Resources

The proposed layover facility is located on filled tidelands approximately 100 feet from the Taunton River shoreline and approximately 20 feet above the river. Since it was filled between 1865 and 1893, the site does not support the protection, restoration or enhancement of living marine resources.

Attainment of Water Quality Goals

The proposed layover facility will meet all applicable state and federal water quality standards and will comply fully with this standard.

Reduction of Flood and Erosion-Related Hazards on Lands Subject to the 100-Year Storm Event or Sea Level Rise

The proposed layover facility will be located approximately 20 feet above the Taunton River, well above the 100-year storm event. The site is not subject to inundation during predicted storm events or sea level rise and is not damage prone or a natural buffer area.

Protection or Enhancement of Public Views and Visual Quality in the Natural And Built Environment of the Shoreline

The primary public views of the Taunton River shoreline potentially affected by the proposed layover facility are from the North Main Street corridor east of the site and the adjacent private residences and

side-streets. These public views, and the associated visual quality will not be substantively affected by the project because the North Main Street corridor is approximately 20 feet above the elevation of the proposed site. The ground elevation continues to rise east of North Main Street to approximately 80 feet above the site at Route 79.

The public views of the layover facility could be further mitigated by screening if deemed necessary during licensing. However, this would be of limited effect in light of the small potential changes in public views resulting from the project.

Preservation of Historic Sites and Districts, Archaeological Sites, and Other Significant Cultural Resources Near Waterways

The proposed layover facility site is filled land and does not contain any known site, district, archaeological site, or other culturally significant resource.

8.9.3.3 Municipal Harbor Plans

The municipal harbor planning process is voluntary, established by the regulations at 301 CMR 23.00. Municipalities may implement local planning goals for their waterfronts. An approved MHP is intended to guide state agency actions related to waterfront development, permitting, and planning, and provides a formal mechanism for local input to the Chapter 91 licensing process. Approved MHPs may substitute numerical provisions regarding building height, setbacks, open space, and ground floor uses within Commonwealth tidelands.

The South Coast Rail project includes construction activities and changes in use within the geographic planning area for two MHPs:

- New Bedford/Fairhaven Municipal Harbor Plan, and
- Fall River Municipal Harbor and Downtown Economic Development Plan.[7]

The following sections describe the South Coast Rail project’s consistency with these MHPs.

New Bedford/Fairhaven Municipal Harbor Plan

The New Bedford/Fairhaven MHP was prepared through a collaborative effort by the Cities of New Bedford and Fairhaven, OCZM, MassDEP, and the Seaport Advisory Council. The New Bedford/Fairhaven MHP was approved by the Secretary of Energy and Environmental Affairs on June 14, 2012.

This planning area includes the proposed sites for the Wamsutta Layover Facility and the Whale’s Tooth Station. However, these facilities are not subject to licensing under Chapter 91 as they would be located on landlocked filled tidelands; they are not required to be consistent with the approved MHP to comply with the provisions of 310 CMR 9.34.

Pursuant to 301 CMR 23.05(3), MassDOT has been an active participant in the development of the New Bedford/Fairhaven MHP as it relates to the South Coast Rail project. The MHP recognizes the importance of restoring rail service as a critical component of transportation and industrial infrastructure in the port of New Bedford.

[7] The Fall River Harbor and Downtown Economic Development Plan is not an approved plan under 301 CMR 23.00 or 310 CMR 9.00.

The New Bedford/Fairhaven MHP identifies the combined Whale's Tooth Station as a suitable location to support commuter rail, local and regional bus service, taxis, and waterfront trolley service, and potentially accommodate future rail and pedestrian links to a water terminal.

Fall River Harbor and Downtown Economic Development Plan

In October 2002, the City of Fall River completed an Economic Development Plan in consultation with a diverse group of regional stakeholders including the OCZM and MassDEP. The plan was prepared with the goal of obtaining approval by the Massachusetts Secretary of Energy and Environmental Affairs under the provisions of Municipal Harbor Plan Approval regulations (301 CMR 23.00). While the Economic Development Plan was submitted to the Secretary for approval, it was not approved, pending further revisions. Therefore, the Economic Development Plan does not meet the regulatory criteria for approved harbor plans and does not serve as formal regulatory guidance for the licensing process.

None of the bridges or culverts subject to Chapter 91 licensing (as listed in Table 8.9-1) are located within Fall River. Nonetheless, the South Coast Rail project has been planned and conceptually designed in a manner consistent with the Fall River Harbor and Downtown Economic Development Plan in terms of supporting water dependent uses and improving public access to the Fall River waterfront while avoiding non-water dependent uses in the DPA or filled tidelands subject to licensing.

8.10 MASSACHUSETTS ENDANGERED SPECIES ACT

This section describes the regulatory context, regulatory requirements, and how the South Coast Rail project would comply with requirements of the MESA protecting state-listed rare species.

8.10.1 Regulatory Context

MESA protects rare plants and animals and their designated critical habitats; the Massachusetts Wetlands Protection Act protects wildlife habitat. NHESP has determined that the Stoughton Alternative would result in a "take" of state-listed rare species and would require a Conservation and Management Permit (CMP). There would be no impacts to federally listed endangered species.

8.10.2 Regulatory Requirements

MESA prohibits "taking" any state-listed rare plants and animals unless specifically permitted for scientific, educational, or propagation purposes, or where a CMP is issued. "Take" includes protection of rare species habitat, and is defined as "*in reference to animals to harass, harm, pursue, hunt, shoot, hound, kill, trap, capture, collect, process, disrupt the nesting, breeding, feeding or migratory activity or attempt to engage in any such conduct, or to assist such conduct, and in reference to plants, means to collect, pick, kill, transplant, cut or process or attempt to engage or to assist in any such conduct. Disruption of nesting, breeding, feeding or migratory activity may result from, but is not limited to, the modification, degradation or destruction of Habitat.*"

The regulations implementing MESA (321 CMR 10.05) state that "[a]ll State Agencies shall review, evaluate, and determine the impact on Endangered, Threatened and Special Concern species or their habitats… and use all practicable means and measures to avoid or minimize damage to such species or their habitats." State agencies are responsible for demonstrating to the Secretary that all practicable means and measures to protect rare species and their habitats have been incorporated into the project

design. A project that would result in a “take” requires a CMP from the NHESP. Additional regulatory requirements of MESA are:

- 321 CMR 10.23(2)(a) requires that an applicant adequately assess alternatives to both temporary and permanent impacts to State-listed species.
- 321 CMR 10.23(2)(b) requires that a CMP may only be issued where “an insignificant portion of the local population would be impacted by the Project or Activity”.
- 321 CMR 10.23(2)(c) requires that a CMP may only be issued where “the applicant agrees to carry out a conservation and management plan that provides a long-term Net Benefit to the conservation of the State-listed species”.
- 321 CMR 10.23(7) establishes certain performance standards including mitigation ratios to achieve the long-term Net Benefit performance standard. These ratios are based on the amount of habitat impacted and the category of State-listed species:
  - Endangered species require a mitigation ratio of 3:1 (three times the amount of affected habitat).
  - Threatened species require a mitigation ratio of 2:1.
  - Special Concern species require a mitigation ratio of 1.5:1.

The Director may approve an alternative mitigation approach that differs from these ratios where the alternative approach is appropriate, considering factors that include but are not limited to:

- The size and configuration of the habitat impact;
- The threats to the affected State-listed species posed by uses or activities located adjacent to or in close proximity to the project;
- The size, configuration and quality of the habitat proposed to be protected;
- The population density of the affected State-listed species; and
- The habitat management and research needs associated with the affected species.

8.10.3 Regulatory Compliance

NHESP has determined that the Stoughton Alternative would result in a “take” of three state-listed rare species: Blanding’s turtle, eastern box turtle, and blue-spotted salamander. The amount of habitat impacted would be determined during the permitting process, based on actual field delineation of rare species habitat, and would include a detailed analysis of actual habitat boundaries. Coordination with NHESP would continue through the selection of a final design and development of a detailed mitigation plan, as described in Chapter 7 of this FEIS/FEIR.

As documented in Chapter 3, MassDOT has evaluated four route alternatives (Attleboro, Stoughton, Whittenton, and Rapid Bus) and determined that none of these alternatives would avoid impacts to rare

species habitat. The USACE has determined that the Stoughton Electric Alternative is the LEDPA, as all of the other alternatives would not meet the project purpose, not be practicable or not be less environmentally damaging than the Stoughton Electric Alternative or a combination of the above. The As demonstrated in Chapter 4.15, *Threatened and Endangered Speices*, the impacts to habitat of each of the state-listed species affected by the Stoughton Alternative would be a negligible portion of the total available habitat.

The Stoughton Electric Alternative is not anticipated to affect the long term persistence of these species' populations. MassDOT has developed a draft Conservation and Management Plan, which has been provided to NHESP for review and comment. MassDOT would implement the final, approved Plan to provide a long-term benefit to impacted species. Elements of the Plan include:

- On and/or off-site permanent habitat protection;
- On and/or off-site habitat restoration and management;
- Measures to protect listed species during construction and to mitigate for barrier effects of the reconstructed track system;
- Research to enhance conservation efforts and rare species recovery; and
- Contribution toward development or implementation of an off-site conservation and protection plan for the impacted species.

Species-specific mitigation ratios and measures for direct impacts that achieve the net-benefit standard are:

- For Blanding's turtle (State Threatened), a 2:1 mitigation ratio is required. To provide a net benefit, MassDOT has agreed to provide funding to protect 25 acres of land potentially used by the Hockomock Swamp population of Blanding's turtle, as well as to fund a study of this population that would determine the size and status of the population, identify nesting areas, identify important non-breeding areas, and identify locations where migratory pathways cross Route 138.
- For eastern box turtle (State Special Concern), a 1.5:1 mitigation ratio is required. To provide a net benefit, MassDOT has agreed to provide funding to the eastern box turtle mitigation bank equivalent to protecting 17 acres, or to protect 17 acres of habitat available to this population.
- For the blue-spotted salamander (State Special Concern), a 1.5:1 mitigation ratio is required. To provide a net benefit, MassDOT has agreed to provide funding to protect approximately 11 acres of land potentially used by the Hockomock Swamp population of blue-spotted salamander.
- MassDOT anticipates that the land protection for the Blanding's turtle and blue-spotted salamander may overlap, and may be combined with wetlands preservation required for wetland mitigation.

NHESP has determined that minor impacts to the habitat of invertebrate species, and other species present along the active New Bedford Main Line and Fall River Secondary (the Southern Triangle), would not constitute a "take" based on the conceptual design.

Implementation of the CMP will ensure that the affected species will realize a net benefit from the South Coast Rail project.

8.11 WILD AND SCENIC RIVERS ACT

Section 7(a) of the Wild and Scenic River Act (16 U.S.C. 1278 *et seq.*) provides that no department or agency of the United States shall assist by loan, grant, license, or otherwise in the construction of any water resources project that would have a direct and adverse effect on the values for which such river was established, as determined by the secretary charged with its administration (33 CFR 320.3(l)).

As discussed in Chapter 4.5, *Visual Resources*, the South Coast Rail project is subject to the Wild and Scenic Rivers Act since portions of the Taunton River were designated as "scenic" or "recreational" river areas under the Act in March 2009. Specifically, the segment along the Fall River Secondary and the segment through Taunton from Weir Street to Route 24 were designated as a "recreational river area," which is defined by the Act as a segment with a partially developed shoreline and ready access.

Consultation with the NPS would be necessary to obtain concurrence that the effects of the South Coast Rail project on the recreational values of the Taunton River would be neither invaded nor unreasonably diminished. The applicability of this consultation requirement for the Stoughton Alternative is summarized below.

The Stoughton Electric Alternative includes the New Bedford Main Line, which crosses the Taunton River just south of Weir Junction. The Stoughton Line also crosses the Taunton River at three locations north of Weir Junction, as well as a tributary to the Taunton River (the Mill River) within 0.25 mile of the Taunton River's main stem. Bridge replacement at all of these locations would affect the visual environment of the Taunton River as regulated by the NPS under the Wild and Scenic Rivers Act. The layover facility site along the Fall River Secondary (Weaver's Cove East) also would affect the visual environment of the Taunton River. The NPS was contacted for consultation. A meeting between MassDOT and representatives from the NPS Wild and Scenic Rivers Program was held in January 2012 to discuss the proposed project. Detailed descriptions of the South Coast Rail project's potential impacts to the Taunton River from the proposed bridge replacement and Fall River Depot Station were provided to the NPS and are described in Chapter 4.10, *Protected Open Space and Areas of Critical Environmental Concern*. Further consultation with NPS is anticipated as the project advances through the design process.

Determining if a project would result in a direct and adverse effect to a designated river requires consideration of aspects of the project potentially impacting the river, and the scope of the evaluation should be consistent with the magnitude and complexity of the project. The evaluation of the potential impact to the Wild and Scenic River designation that may result from the proposed replacement of the Taunton River bridges under the Stoughton Electric Alternative, as required by Section 7[8], is presented below.

[8] Interagency Wild and Scenic Rivers Coordinating Council. 2004. Appendix C: Evaluation Procedure Under "Direct and Adverse."

1. Define the proposed activity.

   The project proponent, MassDOT, proposes to replace four bridges over the Taunton River because the existing bridges are in deteriorating condition and do not meet the safety and performance requirements for the South Coast Rail project. The four bridges are located in Taunton, Massachusetts, as shown on Figure 4.10-23. The bridge replacement project would require 4 years to complete and the bridges would be in operation indefinitely thereafter. The existing multi-span bridges, piers, and abutments would be removed; new abutments and superstructure would be installed. The replacement bridges would be one- or two-span structures. The riverbank would be graded to allow for wildlife passage.

2. Describe how the proposed activity will directly alter within-channel conditions.

   The replacement activities would be conducted at the locations of the existing four bridges, largely within the footprint of the existing bridges. The new abutment locations, behind the existing abutment sites, would slightly extend the bridge length. There would be no changes to the active channel location, channel geometry, channel shape, channel form, or water quality parameters. Navigability of the river would be improved by replacing multi-span structures by one- or two-span structures. There would be no adverse impacts to outstanding resources values of the river channel.

3. Describe how the proposed activity will directly alter riparian and/or floodplain conditions.

   New abutments would be constructed behind the existing abutments, expanding the riparian area and floodplain slightly. The riverbank at these locations would be re-graded consistent with the slope of the bank up- and downstream from the bridge location. The floodplain would be slightly expanded as a result of replacing the abutments. There would be no adverse impacts to outstanding resources values of the riparian area.

   Describe how the proposed activity will directly alter upland conditions.

   The project would not alter upland conditions. The work would be conducted within the existing railroad footprint, using rail-mounted equipment.

5. Evaluate and describe how changes in on-site conditions can/will alter existing hydrologic or biologic processes.

   The project would not adversely alter existing hydrologic or biologic processes. All aspects of the bridge replacement would improve river flow characteristics by replacing the existing multi-span structures with one- or two-span bridges and moving the abutment locations up-bank. Potential impacts to water quality during construction would be managed in accordance with regulatory requirements of the National Pollutant Discharge Elimination System program, specifically described in a project-specific Stormwater Pollution Prevention Plan.

6. Estimate the magnitude and spatial extent of potential off-site changes.

   There would be no off-site changes from the bridge replacement activities that would impact the river.

7. Define the time scale over which steps 3 through 6 are likely to occur.

The bridge construction activities are expected to require 4 years to complete. The bridges would be used indefinitely thereafter.

8. Compare project analyses to management goals.

   The bridge replacements are not expected to adversely affect the achievement or timing of achievement of the management goals and objectives for the Taunton River, as described in the *Taunton River Stewardship Plan*.[9]

9. Make the Section 7 determination.

   The bridge replacements would improve riparian area and floodplain conditions, and would not affect water quality, outstanding resources values, or the recreational river classification. Replacing and using four bridges over the Taunton River is not expected to result in a direct and adverse effect to the recreational nature of the Taunton River in this reach.

8.12 NATIONAL HISTORIC PRESERVATION ACT AND MASSACHUSETTS GENERAL LAW CHAPTER 9

As discussed in detail in Chapter 4.8, cultural resources are regulated at the federal and state levels and are always considered in NEPA and MEPA analyses. At the federal level, Section 106 of the National Historic Preservation Act of 1966 as amended (36 CFR 800) provides the regulatory framework for the compliance guidelines for the identification and evaluation of cultural resources. At the state level, Massachusetts General Laws Chapter 9, Chapter 254, Sections 26-27C, as amended; and 950 CMR 71.00, 950 CMR 70.00 provides the regulatory framework for the state compliance guidelines, under the jurisdiction of the Massachusetts Historical Commission (MHC). Other relevant legislation and regulations include the National Environmental Policy Act of 1969, as amended;[10] Executive Order 11593, “Protection and Enhancement of Cultural Environment;”[11] Sections 106 and 110 of the National Historic Preservation Act of 1966, as amended,[12] implementing regulation 36 CFR 800, as revised January 2001; and, the Procedures for the Protection of Historic Properties (Appendix C) at 33 CFR Part 325 - Processing of Department of the Army Permits.

The historic and archaeological resources intensive surveys for the South Coast Rail project were undertaken in accordance with the Secretary of the Interior’s *Standards and Guidelines for Identification* (48 FR 44720-23), the Massachusetts Historical Commission (MHC) standards and guidelines set forth in *Public Planning and Environmental Review: Archaeology and Historic Preservation* (MHC 1985), and the MHC historic resources survey standards. The survey complies with the standards of the MHC, state archaeologist’s permit regulations (950 CMR 70), the Secretary of the Interior’s *Standards and Guidelines for Identification* (48 FR 44720-23), The Standards of the Massachusetts State Register of Historic Places (State Register), and NPS guidelines for assessing eligibility for listing in the National Register, specifically *National Register Bulletin 15: How to Apply the National Register Criteria for Evaluation*. While the surveys conducted to date have informed the impact analysis, additional surveys

[9] Taunton River Stewardship Council. 2005. *Taunton River Stewardship Plan, Taunton River Wild & Scenic River Study.* Prepared by the Taunton Wild and Scenic River Study Committee, Southeastern Regional Planning & Economic Development District, and National Park Service-Northeast Region.

[10] National Environmental Policy Act of 1969, as amended (42 .S.C. $$ 4321-4347).

[11] Executive Order No. 11593. “Protection and Enhancement of the Cultural Environment,” CFR 154 (1971) reprinted in 16 U.S.C.$470 note.

[12] Advisory Council on Historic Preservation. Sections 106 and 110 of the National Historic Preservation Act of 1966 (January 2001) 36 CFR 800.

will be conducted as necessary when more design information is available to further and more specifically assess potential impacts to cultural resources.

8.12.1 National Historic Preservation Act

Section 106 of the National Historic Preservation Act of 1966 (NHPA) seeks to accommodate historic preservation concerns with the needs of federal undertakings through consultation among agency officials and other parties with an interest in the effects of the undertaking on historic properties. The goal of the consultation is to identify historic properties with the potential to be impacted by the undertaking, assess its effects, and seek ways to avoid, minimize, or mitigate any adverse effects on historic properties.[13]

As the lead federal agency for the South Coast Rail project, the Corps has compliance responsibilities regarding cultural resources under the Procedures for the Protection of Historic Properties (Appendix C) at 33 CFR Part 325 - Processing of Department of the Army Permits, Section 106 of the NHPA as amended, the regulations of the Advisory Council on Historic Preservation (Council) at 36 CFR 800, and NEPA.

8.12.2 Massachusetts General Law Chapter 9

MassDOT serves as the lead state agency and is responsible for identifying and evaluating properties through archaeological and historic architectural surveys in accordance with MGL Ch. 9 Sections 26-27C, as amended; 950 CMR 71.00, 950 CMR 70.00 and MEPA. MGL Chapter 9 Section 26 27C stipulates that any project that requires funding, licenses or permits from any state agency must be reviewed by the MHC.

8.13 GENERAL CONFORMITY WITH CLEAN AIR ACT AND NATIONAL AMBIENT AIR QUALITY STANDARDS (NAAQS)

As discussed in Chapter 4.9, *Air Quality*, the South Coast Rail project is subject to General Conformity (Title 40 CFR Part 93, Subpart B). General conformity provisions only apply in nonattainment and maintenance areas. Given that the project area is nonattainment for the 8 -hour ozone standard, the relevant pollutants for consideration are the two ozone precursors: volatile organic compounds (VOC) and nitrogen oxides (NO_x). The long-term effect of the Stoughton Alternative on VOC and NO_x emissions is beneficial (e.g. reduced emissions relative to the No-Build alternative). Therefore, a conformity determination would not be required to address long-term operational emissions, even if such emissions could be practically controlled by USACE. As discussed in Section 4.9.1.2, long-term operation emissions (such as from diesel locomotives under the diesel rail alternatives), are not indirect emissions within the scope of General Conformity because USACE cannot control them and has no continuing program control over the rail line.

However, General Conformity also applies to peak year construction emissions. The construction-related emissions of this project are a reasonably foreseeable consequence of the USACE Section 404 permit decision. If construction emissions exceed certain *de minimis* criteria, a General Conformity determination could be required. The *de minimis* criteria for this project (ozone nonattainment area in an ozone transport region) are 50 tons/year for VOC and 100 tons/year for NO_x.

[13] Advisory Council on Historic Preservation. Section 106 of the National Historic Preservation Act of 1966 (June 17, 1999) 36 CFR 800.1(a).

The construction schedule and staging of the Stoughton Electric Alternative has not been defined in sufficient detail at this point in the development of the project to quantify construction period VOC and NO_x emissions for comparison to the *de minimis* criteria. The Corps will require the preparation of a General Conformity applicability analysis for peak construction year emissions of the preferred alternative prior to the NEPA Record of Decision. If the *de minimis* criteria are not exceeded, no further review will be required. If the criteria are exceeded, a General Conformity determination (including 30-day public review period) will be required prior to project implementation.

8.14 ARTICLE 97 OF THE COMMONWEALTH OF MASSACHUSETTS

The Secretary of the Executive Office of EEA has defined lands subject to Article 97 as "land or interests in … land owned or held by the Commonwealth or its political subdivisions"[14] that protect these interests. It is assumed that the publicly owned open spaces below that have been identified are Article 97 lands subject to the EEA Article 97 Land Disposition Policy.

The goal of the EEA Policy is to ensure no net loss of Article 97 lands. As a general rule, the EEA and its agencies "shall not sell, transfer, lease, relinquish, release, alienate, or change the control or use of any right or interest of the Commonwealth in and to Article 97 land." Exceptions to this goal are included in the EEA Policy; disposition of Article 97 land is not supported unless exceptional circumstances exist. All other options to avoid use of Article 97 land must be explored and no feasible and substantially equivalent alternatives exist.

The policy requires that EEA agencies minimize land disposition occurrences. All Article 97 land disposition proposals are to be coordinated with the EEA, and any Article 97 land disposition that is recommended must be justified and explained to the Secretary of the EEA. Any Article 97 land disposition must be authorized by enacted legislation and approved by all municipal, state, and federal agencies, authorities, or other governmental bodies as required and empowered.

According to the EEA Policy, Article 97 land disposition cannot be supported unless EEA and its agencies determine that exceptional circumstances exist. A determination of "exceptional circumstances" is subject to all of the following conditions being met:

- All other options to avoid the Article 97 disposition have been explored and no feasible and substantially equivalent alternatives exist;
- The disposition of the subject parcel and its proposed use do not destroy or threaten a unique or significant resource;
- As part of the disposition, real estate of equal or greater fair market value or value in use of proposed use, whichever is greater, and significantly greater resource value are granted to the disposing agency or its designee;
- The minimum acreage necessary for the proposed use is proposed for disposition and, to the maximum extent possible, the resources of the parcel proposed for disposition continue to be protected;

[14] EEA. *1998. Article 97 Land Disposition Policy.* Commonwealth of Massachusetts, Executive Office of Energy and Environmental Affairs, Massachusetts Environmental Policy Act Office: Boston.

- The disposition serves an Article 97 purpose or another public purpose without detracting from the mission, plans, policies and mandates of EEA and its appropriate department or division; and

- The disposition of a parcel is not contrary to the express wishes of the person(s) who donated or sold the parcel or interests therein to the Commonwealth.

To the extent possible based upon readily available information and conceptual engineering plans, an evaluation of the project with respect to these six criteria is provided in Chapter 4.10, *Protected Open Space and Areas of Critical Environmental Concern*. The Stoughton Electric Alternative would require approximately 0.16 acre of Article 97 land acquisition. As described in Section 4.10.4.2, compliance with the Article 97 land disposition exceptional circumstances criteria would be completed for the selected alternative once the engineering design is finalized and replacement sites identified.

8.15 AREAS OF CRITICAL ENVIRONMENTAL CONCERN (ACEC) PROGRAM

As discussed in Chapter 4.10, *Protected Open Space and Areas of Critical Environmental Concern*, ACECs are "those areas within the Commonwealth where unique clusters of natural and human resource values exist and which are worthy of a high level of concern and protection."[15] ACECs are designated by the EEA, and the ACEC program is administrated by the Massachusetts Department of Conservation and Recreation.

Commonwealth regulations[16] indicate that all EEA agencies must take action, administer programs, and revise regulations in order to acquire useful scientific data on the ACEC; preserve, restore, or enhance the resources of the ACEC; and ensure that activities in or impacting on the ACEC are carried out so as to minimize adverse effects on seven environmental resources, as addressed in other chapters of this FEIS/FEIR:

- Marine and Aquatic Productivity: Chapter 4.18, *Chapter 91 Compliance and Coastal Zone Consistency*; Chapter 4.14, *Biodiversity, Wildlife, and Vegetation*; Chapter 4.15, *Threatened and Endangered Species*; Chapter 4.16, *Wetlands*; Chapter 4.17, *Water Resources*.

- Surface and Groundwater Quality: Chapter 4.17, *Water Resources*.

- Habitat Values: Chapter 4.14, *Biodiversity, Wildlife, and Vegetation*; Chapter 4.15, *Threatened and Endangered Species*.

- Storm Damage Prevention or Flood Control: Chapter 4.16, *Wetlands*.

- Historic and Archaeological Resources: Chapter 4.8, *Cultural Resources*.

- Scenic and Recreational Resources: Chapter 4.5, *Visual and Aesthetic Resources*.

- Other Natural Resource Values of the Area: Chapter 4.16, *Wetlands* and Chapter 4.11, *Farmland Soils*.

---

[15] EEA. 2009. 301 CMR 12.03 Areas of Critical Environmental Concern, General Provisions. Commonwealth of Massachusetts, Executive Office of Energy and Environmental Affairs: Boston.

[16] EEA. 2009. 301 CMR 12.12: Effects of Designation. Commonwealth of Massachusetts, Executive Office of Energy and Environmental Affairs: Boston.

The Stoughton Electric Alternative would require the acquisition of one publicly owned parcel within the Hockomock Swamp ACEC in Easton: 0.50 acre of the Southeastern Regional Vocational Tech School land. This land would be used for a traction power substation. The area represents a small proportion of the ACEC and acquisition would not substantively affect any of the resource areas of concern.

8.16 FARMLAND PROTECTION POLICY ACT

The FPPA, P.L. 9798,[17] authorizes the USDA to develop criteria to identify the effects of federal programs on the conversion of farmland to non-agricultural uses. If it is determined that farmland conversion may involve land protected under the FPPA, formal coordination is required per 7 CFR Part 658. The NRCS reviews potential impacts to farmland to determine if the land qualifies as prime or unique farmland or farmland of statewide importance. Forms AD-1006 and CPA-106, which outline direct and indirect impacts to farmland and assign an impact rating at each location, would be submitted by the project for review and scoring by the NRCS. Impacts with scores less than 160 are considered insignificant, between 161 and 200 potentially adverse, and scores over 200 are considered potentially significant. Scores over 160 may require the project to further assess the implications of the proposed action on the farmland and potentially consider alternatives to further minimize or avoid farmland losses. During the environmental review process, agencies having jurisdiction or special use expertise may provide a letter which may include recommended measures to mitigate project effects.

As discussed in Chapter 4.11, *Farmland Soils*, the NRCS has not been requested to complete a Farmland Conversion Impact Rating for any of the South Coast Rail project alternatives at this time because the impacts are not expected to be significant. Drafts of the NRCS Farmland Conversion Impact Rating Forms AD-1006 and CPA-106 have been prepared for sites larger than 2 acres where designed farmland soils may be impacted. These forms are included in Appendix 4.11-A. Subject to comments from agencies with jurisdiction or special use expertise concerning important farmland, mitigation measures may be developed as appropriate.

None of the sites that impact farmland soils resulted in a score greater than 160 on the draft Form AD-1006 or CPA-106. These findings indicate that the Stoughton Electric Alternative would not have a detrimental impact on agricultural lands nor would it convert land from active agricultural use to nonagricultural use.

8.17 MASSACHUSETTS EXECUTIVE ORDER 193

EO 193 directs state agencies to avoid conversion of agricultural lands to non-agricultural uses. Three criteria are evaluated to determine if a parcel is considered agricultural land for purposes of EO 193:

- the presence of soil types capable of supporting or contributing to present or potential commercial agriculture
- current and historic use for agriculture, and
- absence of non-farm development

Impacts to mapped areas of farmland soils were evaluated where conversion of previously undeveloped land is proposed as part of the South Coast Rail project. Although several sites are located within

[17] United States Department of Agriculture, Farmland Protection Policy Act, 1981, (Public Law 97-98, 7 U.S.C. 4201).

mapped areas of farmland soils, none are currently in agricultural production. All non-corridor sites are adjacent to existing rail corridors and public roadways and are located in areas that are at least partially developed and are therefore less suitable for conversion to agricultural usage.

The Stoughton Electric Alternative would not convert land from active agricultural use to nonagricultural use.

8.18 MASSACHUSETTS CONTINGENCY PLAN (310 CMR 40.0000)

As discussed in Chapter 4.12, *Hazardous Materials*, the spill or release of Oil or Hazardous Materials (OHM) in the process of constructing the South Coast Rail project is an unlikely event, and measures would be required to prevent and control any such spills. The construction contractors would implement a Spill Control Program in compliance with the Massachusetts Contingency Plan (310 CMR 40.0000, “the MCP”) and MBTA policy. These measures would be employed both at the rail reconstruction sites and station construction sites.

Properties with confirmed OHM impacts are generally managed in accordance with the MCP, 310 CMR 40.0000 and associated policies or guidance issued by the DEP. However, depending on the type and concentrations of OHM present at a property, other regulations implemented by the Commonwealth of Massachusetts or the USEPA may apply.

The Stoughton Electric Alternative would require acquisition of properties with RECs that would require further investigation. In each case, remediation or soil/groundwater management during construction could be required.

For contaminated property owned by MassDOT, response actions would be required pursuant to the milestones outlined in the MCP. Notification to the DEP would be required if a reporting condition is identified as per the MCP or if OHM is detected in soil and/or groundwater above the applicable standards, referred to as the Reportable Concentrations. A Licensed Site Professional (LSP) would then most likely need to be retained to verify that notification is required, to further assess and manage the site, direct response actions, and specify procedures for work performed in the contaminated areas, such as soil excavation, in accordance with the MCP and, if need be, to render appropriate Opinions. The LSP would also determine if risk reduction measures are required.

To extend MCP deadlines for response action and report submittals so that the response actions can be coordinated with the construction of the stations, layovers, and expansion of the rail lines, the application for a Special Designation Permit (as per 310 CMR 40.0060 of the MCP) may be warranted.

At many sites containing impacted soil, it is often not possible to reach a regulatory endpoint by using soil excavation and off-site disposal as the only type of remediation. It is advisable to explore other options such as the re-use of soil in order to minimize the quantity of soil to be excavated and disposed off-site. For low levels of impacted soil where a risk assessment shows an unacceptable risk for current and future unrestricted use, a deed restriction consisting of an Activity and Use Limitation (AUL) may be implemented after construction is completed to meet a regulatory endpoint. As per 310 CMR 40.1012(3)(c) of the MCP, AULs are not required within railroad rights-of-way.

Soil impacted with OHM above the Reportable Concentrations that is encountered during the implementation of the South Coast Rail project would be managed appropriately in accordance with the MBTA Design Construction Standard Specifications, Section 02282, entitled “Handling, Transportation

and Disposal of Excavated Material." Preliminary assessment activities may assist in identifying the type and quantity of OHM impacted media which would require management under these protocols and help select the optimal disposal methods and/or destination prior to generation. A summary of the MBTA Specification is provided in the following sections of Chapter 4.12, *Hazardous Materials*:

- 4.12.4.1 Management of Impacted Soil
- 4.12.4.2 Management of Impacted Groundwater;
- 4.12.4.3 Management of Hazardous Demolition Debris and Used Railroad Ties
- 4.12.4.4 Health and Safety Requirements
- 4.12.4.5 Closure Reports

9 PUBLIC INVOLVEMENT AND AGENCY COORDINATION

9.1 INTRODUCTION

This chapter provides a summary of public involvement and agency coordination activities conducted by the Corps and/or MassDOT in the development of the FEIS/FEIR.

9.2 PUBLIC INVOLVEMENT

The Corps published a NOI to prepare an Environmental Impact Statement on the South Coast Rail Project Section 404 permit application in the Federal Register on October 31, 2008.[1] For the MEPA process, the South Coast Rail ENF was noticed in the Environmental Monitor on November 24, 2008. Comments on the NOI and ENF were accepted until January 9, 2009. On February 20, 2009, additional information on ridership studies was provided for public review and the deadline for comments on the ENF was extended until March 17, 2009.

The Corps and the MEPA Office of the Massachusetts Executive Office of EEA held joint Corps/MEPA-sponsored public scoping meetings on December 2 and 3, 2008.[2] The scoping meetings provided an opportunity for the public, interested groups and local, state and federal agencies to comment on potential issues or concerns associated with the proposed project. The outcome of the scoping meetings and the public comment period following those meetings was used to help shape the issues studied in the DEIS/DEIR.

ENF comments were received from federally- and state-elected officials; USEPA; the National Park Service; eight state agencies; four regional agencies; ten municipalities; 13 non-governmental organizations; and 45 individuals and businesses. Pursuant to existing MEPA requirements,[3] MassDOT prepared a Response to Comments on the ENF, which was included as an appendix to the DEIS/DEIR. While the responses to the ENF comments were prepared solely by MassDOT, the Corps considered all comments received as part of the preparation of the DEIS/DEIR and this FEIS/FEIR.

In addition to the public scoping meetings by the Corps/MEPA office, MassDOT has conducted its own public meetings and workshops throughout the study process. MassDOT notified interested parties, elected officials, and residents of upcoming meetings and new information through fact sheets, newspaper announcements, flyers and posters, cable-televised meetings, and/or e-mail notifications. Additional information on MassDOT's public outreach is provided on the project website (http://www.mass.gov/southcoastrail).

In March 2011, the Corps released the DEIS/DEIR for the South Coast Rail project[4] for public review and comment. The Corps published a public notice announcing the availability of the joint DEIS/DEIR on March 23, 2011, as well as a notice in the Federal Register on March 25, 2011. The notices provided information about the DEIS/DEIR availability, including the website where an electronic version of the

[4] U.S. Army Corps of Engineers, New England District. 2011. *Draft Environmental Impact Statement/Draft Environmental Impact Report: South Coast Rail Project, Bristol, Plymouth, Norfolk and Suffolk Counties, Commonwealth of Massachusetts.* U.S. Army Corps of Engineers New England District, Concord, MA.

DEIS/DEIS is posted;[5] a listing of the 24 public libraries where copies of the DEIS/DEIR were made available for public review; the comment period and deadline; and public hearing dates and locations. The DEIS/DEIR was publicized in the MEPA Environmental Monitor on March 23, 2011. After detailed review, on June 29, 2011 the Secretary issued a Certificate on the 2011 DEIR.

Two public hearings were held to receive comments on the DEIS/DEIR. On the evening of May 4, 2011, a public hearing was held at Qualters Middle School, 240 East Street in Mansfield. On the evening of May 5, 2011, a second hearing was held at the Keith Middle School, 225 Hathaway Boulevard in New Bedford. Public hearing transcripts are included in Volume III of the FEIS/FEIR. Written comments on the DEIS/DEIR were accepted until the close of the public comment period on May 27, 2011, and are available on the MassDOT project website.[6] Responses to DEIS/DEIR comments are provided in Volume III of this FEIS/FEIR.

MassDOT will host two open houses to provide information on the FEIS/FEIR. Subject area experts will be available to talk directly with participants and answer questions. The open houses will be scheduled in the Taunton area and in the Fall River/New Bedford area. The meetings will be scheduled during the comment period on the FEIS/FEIR, probably in early October. The dates will be posted on the project website, shared in an email blast to everyone on the database, and announced in regional and local publications on the South Coast. Comment sheets will be available at the open houses, should a participant want to comment on site, and there will be information on how to submit comments in writing during the comment period. MassDOT will ask local cable television stations to provide coverage of the open houses and/or Task Force meeting.

MassDOT will also present the FEIS/FEIR at a meeting of the Commuter Rail Task Force on October 16 (this meeting will take place on the south coast; the location has not been determined). The project team will also present information on the document by request, to elected officials and organizations in the region.

Given the size of the document, MassDOT is producing a Guide to the FEIS/FEIR. The guide will summarize the principal conclusions of the document and highlight the material contained in each section so that the public can easily locate and review topics of interest. In addition, MassDOT will publish a Fact Sheet with similar information at a higher level, also advising the public on how to participate in the open houses, where to find the FEIS/FEIR or get a copy of the document, and how to comment on the FEIS/FEIR.

MassDOT will announce the availability of the FEIS/FEIR as widely as possible, release a statement to the media; post information on the project website; send an email announcement to the database; and share information through the Commuter Rail Task Force, elected and municipal officials.

In accordance with the CEQ NEPA regulations, the Corps can issue a Record of Decision no sooner than thirty days after publication in the Federal Register of the notice of availability of the FEIS/FEIR (40 CFR § 1506.10).

9.3 AGENCY COORDINATION

Cooperating agencies are federal agencies that have legal jurisdiction or special expertise in the issues being addressed in an EIS and assist the lead agency in the NEPA process (40 CFR 1501.6). Four federal

[5] http://www.nae.usace.army.mil/Missions/ProjectsTopics/SouthCoastRail.aspx.
[6] http://www.southcoastrail.com/env_Review.html.

agencies accepted the Corps' request to serve as cooperating agencies for the preparation of the South Coast Rail EIS: the USEPA, the FHWA, the FTA, and the FRA. Copies of the cooperating agency status acceptance letters from the above listed agencies are provided in Appendix 9.3-A.

MassDOT convened an Interagency Coordinating Group of federal and state regulatory agencies to inform the environmental review process. In addition to the South Coast Rail Project Manager for the Corps, representatives of the following entities were invited to participate in the Interagency Coordinating Group:

- United States Environmental Protection Agency
- United States Fish and Wildlife Service
- Federal Highway Administration
- Federal Transit Administration
- National Marine Fisheries Service
- Narragansett Indian Tribe
- Wampanoag Tribe of Gay Head (Aquinnah)
- Massachusetts Executive Office of Energy and Environmental Affairs
- Massachusetts Environmental Policy Act Office
- Massachusetts Bay Transportation Authority
- Massachusetts Department of Environmental Protection
- Massachusetts Office of Coastal Zone Management
- Massachusetts Department of Conservation and Recreation, Areas of Critical Environmental Concern Program
- Massachusetts Department of Fish and Game, Natural Heritage and Endangered Species Program
- Massachusetts Historical Commission
- Southeastern Regional Planning and Economic Development District

This group began meeting in September 2007 and met monthly through November 2009, and less frequently through July 2010. The group meets with the objective of informing the environmental review process for the project by discussing key items, including project purpose and need, scope of alternatives for study, methodology for obtaining data, and analysis of data. Table 9-1 lists Interagency Coordinating Group meeting topics and dates.

In addition, as required by the Secretary's Certificate on the ENF, a working group was formed to develop a scope for the analysis of greenhouse gas emissions and the potential secondary effects of the proposed project with and without the implementation of the Corridor Plan. Participants in this working group included representatives of the USEPA, Corps, and DEP. Two subgroups were also formed. A wetland subgroup was created to review wetland impacts and potential mitigation sites, which met from May through September 2012. The second subgroup was formed to develop smart growth monitoring plans and metrics, and met in Spring 2012.

A full record of group-approved meeting minutes is posted on MassDOT's project website: www.mass.gov/southcoastrail.

Table 9-1 Interagency Coordinating Group Meetings to Date

Meeting Topic	Date
Project Kickoff and Introduction	September 25, 2007
Project Purpose and Need – Draft	October 23, 2007
Project Purpose and Need – Draft: Phase 1 Screening Criteria	November 27, 2007
Project Purpose and Need – Draft: Phase 1 Screening Criteria; Review of Civic Engagement Input	December 19, 2007
Project Purpose and Need – Final: Phase 1 Screening Criteria	January 3, 2008
Phase 1 Screening Criteria – Final: Range of Phase 1 Alternatives	January 10, 2008
Phase 1 Analysis – Step 1 Screening Criteria Results	February 14, 2008
Phase 1 Analysis – Concurrence on Step 1 Screening Criteria Results; Review Step 2 Results	February 21, 2008
Phase 1 Analysis – Step 2 Concurrence; Review Step 3 Results and Conclusion of Phase 1	February 28, 2008
Phase 1 Analysis – Concurrence on Step 3 Results	March 4, 2008
Phase 1 Analysis – Draft Report; Review of Civic Engagement Input; Step 4 (Circling Back) Analysis	March 21, 2008
Phase 1 Analysis – Concurrence on Advancing Alternatives	April 1, 2008
Smart Growth Corridor Plan	May 27, 2008
Ridership Modeling; Role of the Interagency Coordinating Group	June 19, 2008
Environmental Data Collection Protocols, Potential Station Locations and Rail Operational Analysis	July 17, 2008
Proposed Station Locations; Environmental Review; Data Collection Protocols and Modeling	September 16, 2008
Preliminary Assessment of Alternatives; Environmental Notification Form	October 24, 2008
Discussion on Content of Environmental Notification Form	December 15, 2008
ENF Comments from MEPA; Priority Mapping; Ridership Memo	January 22, 2009
Supplemental Ridership Memo	February 26, 2009
Subcommittee Meeting on Wetlands	April 16, 2009
Subcommittee Meeting on Greenhouse Gases	May 5, 2009
Subcommittee Meeting on Secondary and Cumulative Growth Impacts	May 7, 2009
CAPS model; Secondary Growth Methodology; Wetlands Mapping Methodology	June 18, 2009
CAPS model; Secondary Growth and GHG methodology	July 21, 2009
Rail and Bus operations; Corridor Plan	August 20, 2009
DEIS Process; Secondary Growth Impacts Methodology and Results: Alternatives Analysis	October 22, 2009
CAPS Results' Secondary Growth Impacts	November 12, 2009
Subcommittee meeting on wetland mitigation	February 1, 2010
Subcommittee meeting on wetland mitigation	May 22, 2010
Alternatives Analysis	July 21, 2010
DEIS Review	March 30, 2011
Alternatives Analysis	June 13, 2012

Meeting Topic	Date
Wetland Impacts and Mitigation	May 4, 2012
Wetland Impacts and Mitigation	July 9, 2012
Wetland Impacts and Mitigation	August 29, 2012
Wetland Impacts and Mitigation	September 10, 2012
Smart Growth Monitoring Plan	April 26, 2012
Smart Growth Monitoring Plan	June 27, 2012

13 ACRONYMS AND ABBREVIATIONS

AAI	All Appropriate Inquiry
ACEC	Area of Critical Environmental Concern
ADA	Americans with Disabilities Act
AHCW	Automatic Highway Crossing Warning
APE	Area of Potential Effect
APR	Agricultural Preservation Restriction
ASTM	American Society for Testing and Materials
ATR	Automatic Traffic Recorder
BLSF	Bordering Lands Subject to Flooding
BM	BioMap
BMP	Best Management Practice
B.P.	Before Present
BVW	Bank, Bordering Vegetated Wetlands
CAAA	Clean Air Act Amendments
CAPS	Conservation Assessment and Prioritization System
CEQ	Council on Environmental Quality
CERCLIS	Comprehensive Environmental Response, Compensation and Liability Information System
CFR	Code of Federal Regulations
Chapter 91	Massachusetts General Law Chapter 91
CIR	Color-Infrared
CMP	Conservation and Management Plan
CO	Carbon Monoxide
CO_2	Carbon Dioxide
COC	Constituents of Concern
Corps	U.S. Army Corps of Engineers (also USACE)
CPI	Consumer Price Index
CSO	Combined Sewer Overflow
CSX	CSX Transportation, Inc.
CTEC	Centralized Electric and Traffic Control
CTPS	Central Transportation Planning Staff
CVP	Certified Vernal Pool
CWA	Clean Water Act
CWCS	Comprehensive Wildlife Conservation Strategy
CWR	Continuous Welded Rail
CZM	Coastal Zone Management
CZMP	Coastal Zone Management Plan
dB	Decibels
DCAM	Division of Capital Asset Management
DCR	Department of Conservation and Recreation (Massachusetts)
DEIR	Draft Environmental Impact Report
DEIS	Draft Environmental Impact Statement
DEP	Massachusetts Department of Environmental Protection (also MassDEP)

DFW	Massachusetts Division of Fisheries and Wildlife
DIF	District Improvement Financing
DO	Dissolved Oxygen
DOT	Department of Transportation
DPA	Designated Port Area
EEA	Massachusetts Executive Office of Energy and Environmental Affairs
EIR	Environmental Impact Report
EIS	Environmental Impact Statement
ENF	Environmental Notification Form
EO	Executive Order
EOHED	Executive Office of Housing and Urban Development (Massachusetts)
EOT	Massachusetts Executive Office of Transportation and Public Works (now MassDOT)
EPA	U.S. Environmental Protection Agency (also USEPA)
EPH	Extractable Petroleum Hydrocarbon
ERNS	Emergency Response Notification System
ESA	Environmental Site Assessment
ESA	Endangered Species Act (Federal)
FEIR	Final Environmental Impact Report
FEIS	Final Environmental Impact Statement
FHWA	Federal Highway Administration
FRA	Federal Railroad Administration
FREP	Fall River Executive Park
FPPA	Farmland Protection Policy Act
FTA	Federal Transit Administration
GATRA	Greater Attleboro Taunton Regional Transit Authority
GHG	Greenhouse Gases
GIS	Geographic Information Systems
GWSA	Global Warming Solution Act
HCM	*Highway Capacity Manual*
HOV	High Occupancy Vehicle
HSIPR	High Speed Intercity Passenger Rail
HSR	High-speed Rail
Hz	Hertz
IBA	Important Bird Area
ICG	Interagency Coordinating Group
IEI	Index of Ecological Integrity
ISO	Independent System Operator
ips	Inches per Second
IWPA	Interim Wellhead Protection Area
JTW	Journey-to-Work
kV	Kilovolt
Ldn	Day-Night Averaged Sound Level
LEDPA	Least Environmentally Damaging Practicable Alternative
Leq	Energy-Averaged Equivalent Sound Level
LID	Low Impact Development
LOS	Level of Service
LNG	Liquid Natural Gas

LRTP	Long Range Transportation Plan
LSF	Land Subject to Flooding
LSP	Licensed Site Professional
LUHPPL	Land Use with Higher Potential Pollutant Loads
LUW	Land Under Waterbodies and Waterways
MAPC	Metropolitan Area Planning Council
MAS	Maximum Authorized Speed
MassDEP	Massachusetts Department of Environmental Protection (also DEP)
MassDOT	Massachusetts Department of Transportation
MBTA	Massachusetts Bay Transportation Authority
MCP	Massachusetts Contingency Plan
MCRR	Massachusetts Coastal Railroad
MCZMP	Massachusetts Coastal Zone Management Program
MEPA	Massachusetts Environmental Policy Act
MESA	Massachusetts Endangered Species Act
MGL	Massachusetts General Law
MHC	Massachusetts Historical Commission
MIPAG	Massachusetts Invasive Plant Advisory Group
mips	Micro Inch per Second
$MMTCO_2e$	Million Metric Tons of Carbon Dioxide Equivalent
MOA	Memorandum of Agreement
MOVES	Motor Vehicle Emissions Simulator
MPO	Metropolitan Planning Organization
MRA	Multiple Resource Area
MSAT	Mobile Source Air Toxic
MUTCD	Manual of Uniform Traffic Control Devices
NAAQS	National Ambient Air Quality Standards
NAICS	North American Industry Classification System
National Register	National Register of Historic Places
NCHRP	National Cooperative Highway Research Program
NEC	Northeast Corridor
NEPA	National Environmental Policy Act
NHESP	Natural Heritage and Endangered Species Program
NHL	National Historic Landmark
NHPA	National Historic Preservation Act
NLEV	National Low Emission Vehicle
NMFS	National Marine Fisheries Service
NO_x	Nitrogen Oxides
NOAA	National Oceanic and Atmospheric Administration
NOI	Notice of Intent
NPDES	National Pollutant Discharge Elimination System
NPL	National Priorities List
NPS	National Park Service
NRCS	Natural Resources Conservation Service
O&M	Operations and Maintenance
OCC	Operational Control Center
OCPC	Old Colony Planning Council
OCS	Overhead Catenary System

OCS	Overhead Contact System
OHM	Oil or Hazardous Materials
ORAD	Order of Resource Area Delineation
ORW	Outstanding Resource Water
OSRD	Open Space Residential Development
PA	Programmatic Agreement
PAH	Polynuclear Aromatic Hydrocarbon
PCB	Polychlorinated Biphenyl
PDA	Priority Development Area
PE	Preliminary Engineering
PEM	Palustrine Emergent Marsh
PFO	Palustrine Forested Wetland
PM	Particulate Matter
POW	Palustrine Open Water
PPA	Priority Preservation Area
ppm	Parts Per Million
PSS	Palustrine Shrub Scrub
PTC	Positive Train Control
PVP	Potential Vernal Pool
RA	Riverfront Area
RAO	Response Action Outcome
RCRA	Resource Conservation and Recovery Act
REC	Recognized Environmental Condition
RFG	Reformulated Gasoline
RMS	Root Mean Square
ROS	Remedy Operation Status
ROSP	Regional Open Space Plan
ROW	Right-of-Way
RPA	Regional Planning Agency
RTA	Regional Transit Authority
RTDM	Regional Travel Demand Model
RTN	Release Tracking Number
RTP	Regional Transportation Plan
SCADA	Supervisory Control and Data Acquisition
SHPO	State Historic Preservation Office
SIP	State Implementation Plan (for air quality)
SRPEDD	Southeastern Regional Planning and Economic Development District
SRTA	Southeastern Regional Transit Authority
SSA	Sole Source Aquifer
STIP	State Transportation Improvement Program
SWL	Solid Waste Landfill
SWPPP	Stormwater Pollution Prevention Plan
TAZ	Traffic Analysis Zone
TCP	Traditional Cultural Property
TDR	Transfer of Development Rights
THPO	Tribal Historic Preservation Officer
TIF	Tax Increment Financing
TIGER	Transportation Investment Generating Economic Recovery

TIP	Transportation Improvement Program
TMC	Turning Movement Count
TMDL	Total Maximum Daily Load
TNM	Traffic Noise Model
TOD	Transit-oriented Development
TREDIS	Transportation Economic Development Impact System Model
TSD	Storage and Disposal
TSS	Total Suspended Solids
USACE	U.S. Army Corps of Engineers (also Corps)
USDA	U.S. Department of Agriculture
USDOI	U.S. Department of the Interior
USEPA	U.S. Department of Environmental Protection
USFWS	U.S. Fish and Wildlife Service
USGS	U.S. Geological Survey
USPS	United States Postal Service
UST	Underground Storage Tank
v/c	Volume–to–Capacity (ratio)
VdB	Vibration Velocity Levels in Decibels
VMT	Vehicle Miles Travelled
VOC	Volatile Organic Compound
VPH	Volatile Petroleum Hydrocarbon
WMA	Wildlife Management Area
WPA	Massachusetts Wetlands Protection Act
WSC	Wooded Swamp Coniferous
WSD	Wooded Swamp Deciduous
WSM	Wooded Swamp Mixed
µPa	Micropascals
